TABLE OF CONTENTS

MINING AND SCIENTIFIC PRESS

ESTABLISHED MAY 24, 1860.

CONTROLLED BY T. A. RICKARD.

H. FOSTER BAIN - - - - - - EDITOR
THOMAS T. READ - - - - ASSOCIATE EDITOR
T. A. RICKARD - - - EDITORIAL CONTRIBUTOR

SPECIAL CONTRIBUTORS:

A. W. Allen. Charles Janin.
Leonard S. Austin. James F. Kemp.
Courtenay De Kalb. C. W. Purington.
J. R. Finlay. C. F. Tolman, Jr.
F. Lynwood Garrison. Horace V. Winchell.

PUBLISHED WEEKLY
BY THE DEWEY PUBLISHING COMPANY AT
420 MARKET STREET, SAN FRANCISCO.
Telephone: Kearny 4777. Cable Address: Pertusola.
Code: Bedford McNeill (2 editions).

BRANCH OFFICES:

CHICAGO—734 Monadnock Bdg. Tel.: Harrison 1620 and 636.
NEW YORK—29 Broadway. Telephone: Rector 4439.
LONDON—The Mining Magazine, 819 Salisbury House, E. C. Cable Address: Oligoclase.

ANNUAL SUBSCRIPTION:

United States and Mexico.... $3
Canada $4
Other Countries in Postal Union.....21 Shillings or $5
News Stands, 10c. per Copy.
On Library Cars of Southern Pacific Coast Trains.

L. A. GREENE - - - - - Business Manager

Entered at San Francisco Postoffice as Second-Class Matter.

EDITORIAL

Greeting

Editors, as well as other people, enjoy writing their friends at Christmas and New Year. Unfortunately, speaking for ourselves at least, preparation of an annual review number interferes sadly with holiday pleasures. No great good comes except through elimination, and it is probably safe to assume that the wealth of material appearing in this issue of the *Mining and Scientific Press* will be received as sufficient substitute for the individual letters the Editors would have liked to send to their many friends around the world. After all, it is the primary function of the editor of a technical journal to gather and spread before his readers the best there is of current knowledge regarding practice. The pleasant friendships that are formed are by-products, though to the editor himself they may represent the difference between success and failure; just as by-products do in many another instance. No editor may succeed save through the help of friends, and therefore, gentlemen, for myself and my associates, I wish first of all to thank you for your generous friendship. The men who have helped in preparation of this issue; those who in the course of the past year have contributed articles, new items, or friendly suggestions; those who when requested have patiently dug up facts from records, or collected

notes on processes: the engineers who have sent their cards for publication in our professional directory; the advertisers who, through a year none too good from a selling viewpoint, have given generously of their business; and, last but most numerous of all, you, the widely scattered and usually "gentle" readers;—to all of you our thanks are due, and are gladly given. Your continued support demonstrates that there is a field for high-class technical journalism, for something better and more informing than thinly disguised manufacturer's catalogs or stock-broker's letters, for something more timely and more human than severely technical proceedings of learned societies. It is this field that the *Mining and Scientific Press* claims for its very own. If we print less of market news than others, if there be counties in the United States or districts abroad that occasionally fail of mention, if we leave ancient details of practice mainly to text-books, it is because we believe that mining engineers care most for fresh technological data and next for discussion of the larger currents of human affairs that vitally influence their work. I repeat that success comes only through elimination of the less important, and, while editors are not infallible of judgment, the fact that the *Press* has grown while pursuing the policy outlined, indicates that it has won approval. Life's success is measured not alone in dollars, even among miners who devote their energies to increasing the world's stock of gold and silver, and the *Mining and Scientific Press* wants more than the largest circulation and the greatest advertising clientele. It wants the greatest measure of confidence of the men of the mining world, and with the continued help of our friends we shall strive always to merit and to hold that confidence. Having this, we have faith to believe that all these other things will be added unto us.

During the year just closed, fortune has been kind in that there have been but few changes in our staff. Death took from among our special correspondents T. Lane Carter, one especially gifted, having the eye to see and the pen to describe the interesting places of the world. Mr. M. W. von Bernewitz, whose experience in Australasia has given him a fund of practical knowledge, has come to strengthen our force.

It would be invidious to single out the names of those to whom especial thanks are now due. The table of contents and the advertising pages show those who have mainly contributed. The lists include the leaders in the profession and among the manufacturers. We are proud of their support, and we believe that it indicates that the *Mining and Scientific Press*, with a record of over half a century of useful work, is today the 'organ of the profession'—rather than a private money-making venture. This is at least the ideal of the editors, the publisher, and the stockholders. The degree to which we shall continue to realize our ideals rests with you, gentlemen of the ancient and honorable profession of mining. And so, on behalf of myself and associates, I again thank you for your past and present support and, wishing you all good things in the New Year, confidently ask its continuance.

H. Foster Bain.

ESTIMATES of the production of the Butte district for the year just closed place it at 320,000,000 pounds of copper, 50,000,000 pounds of zinc, and $8,000,000 in silver and gold, having a total value of between $65,000,000 and $70,000,000.

CLOSE of the year in Australia found labor troubles prevalent or impending in many districts. Kalgoorlie advices are to the effect that a general strike may come at any time. Drought, injuring the crops, has raised the cost of living, and the men are restive. Decreasing yield and steadily mounting expense multiply the troubles of the operator, and just where the balance shall rest is not easily determined.

FIFTY YEARS AGO, as we learn from the *Mining and Scientific Press* of January 4, 1862, then in its third volume and still "the only mining, mechanical, and scientific paper on this continent," floods were interfering with the gold yield of California, J. D. Whitney was about to present his report to the legislature, and "Augustin's Method of Extracting Silver with Salt Water' was sufficiently new to warrant careful description.

COMMODITY prices during the year, according to Bradstreet's index numbers, have shown a marked upward tendency, the number for November being 9.478 as compared with an average of 8.713 for 1911. The composite pig iron price December 1 was 17.400, compared with 17.226 for November and 14.005 for 1911, according to *The Standard Metal Digest*. The index for general metal prices shows an increase greater than for general commodities.

FEW contributions of more general and immediate importance to miners have been made by geologists than the discovery of the phenomenon of secondary enrichment, its analysis, and the formulation of criteria for its recognition. We are especially glad to present this week the first part of a general discussion of the subject written by Mr. C. F. Tolman, Jr., whose wide experience in Mexico and the Southwest gives him especial familiarity with those types of copper deposits in which secondary enrichment is especially well displayed.

MINING companies in British Columbia have had an unusually prosperous year, having declared in dividends during 1912 a total of $1,312,876. The Hedley Gold Mining Company leads with a declaration of $360,000, or at the rate of 30 per cent, while the Standard Silver-Lead Mining Company, with $425,000, exceeds in amount, but not in rate, having paid 21¼ per cent. The British Columbia Copper Company has paid $177,512 and declared an additional dividend of $88,756, payable early this month, while the Le Roi No. 2, Ltd., has paid $29,400, or at the rate of one shilling per share. The gratifying total of dividends would have been considerably larger, under normal circumstances, for the Granby Consolidated Mining, Smelting & Power Company, Ltd., made large operating profits during the year that were retained to finance the construction of the new plant at Hidden Creek.

PHILIPPINE statistics for 1912 are not yet available. In 1911 the total value of the mineral output was $1,381,402. The output has been growing at the rate of a quarter to a half million dollars each year. The increase in gold production alone in 1912 amounted to more than $200,000. A full report will be presented later.

METALLURGICAL advances are treated with unusual fullness in this number of the *Mining and Scientific Press*, in accordance with our established policy of giving first place to technology rather than market news. Even this does not exhaust our ammunition. Mr. J. W. Hutchinson has prepared an account of his methods of treating concentrate that fittingly supplements his series of articles on the 'Operation of the Goldfield Consolidated Mill,' which we published in 1912. Originally planned for this number, the article has been held over in order to allow adequate room for illustrations.

LEAD SMELTING in 1912 did not attract the attention that was lavished upon copper smelting. Nevertheless, the year was not without significant events, among which first place must be given to the opening of the Pine Canyon smelter of the International Smelting & Refining Company. The entry of this company into the field long dominated by the American Smelting & Refining Company has already resulted not only in competition in buying but in stimulating development. Mr. L. S. Austin has prepared for us a most interesting description of the new plant. We had hoped to include it in this, our review number, but have been compelled regretfully to set it aside for later publication.

AMONG features of this issue that we present with especial pleasure are letters to Western mining men from the efficient and hard-working directors of two of the great bureaus at Washington, Mr. J. A. Holmes of the Bureau of Mines, and Mr. George Otis Smith of the United States Geological Survey. Both speak for institutions of much usefulness that are justly esteemed, not only in the Western states, but wherever mining is looked upon as a dignified calling and a serious business. In turn, the good opinion of the men in the field is highly regarded at Washington. The recent suggestion of the Prospectors Alliance that all Government bureaus be boycotted shows a lamentable lack of ability to discriminate between good and evil.

ONE of the features of 1912 on the Pacific Coast was the revival of the California Miner's Association, which held a particularly successful session in December. Workingmen's compensation, tailing disposal, the Panama-Pacific Exposition, and other topics were discussed, but the keenest interest was evinced when speakers touched upon the relations of the miner to the Government. With admirable poise, Mr. W. C. Ralston, president and chairman of the committee in charge, had arranged for speakers on both sides of each question. In editorial comment at the time, we pointed out that, to one listening, the debate appeared one-sided, since it happened that more of those criticizing than defending the Government were able to attend. We take especial pleasure, therefore, in presenting this week the first part of the excellent general statement in behalf of the Government prepared by Mr. W. C. Mendenhall, himself a citizen of California, at the request of the Secretary of the Interior. In debate each necessarily argues but one side of a case, and in a sense it is fair to say each speaks from a selfish viewpoint—from the one nearest his own heart. We are sure, however, that readers of Mr. Mendenhall's paper, however much they may have been stung by a sense of injustice suffered, will recognize the earnest purpose to be fair that is the underlying motive. The Government has been occasionally unfortunate in its choice of agents, as have the miners in choice of advocates. We believe that there is no necessary conflict and that nothing will so promote agreement as further frank interchange of ideas.

IDENTITY of names leads often to confusion, and when to it is added similarity in position, it is not surprising that credits and debits get sadly mixed. Mr. Robert Bell, late acting director of the Geological Survey of Canada, has been given undesirable publicity in connection with the Hawthorne trial and some of it has fallen undeservedly on Mr. J. Mackintosh Bell, formerly director of the Geological Survey of New Zealand. Mr. Robert Bell is a geologist of the old school mainly known for his work as an explorer. He has excellent things to his credit, but no especial qualifications for passing upon mining properties. Mr. J. M. Bell is a younger man, who after service in Canada and graduation at Queen's and Harvard, served with distinction in New Zealand. Later he joined an excellent firm of engineers and has recently been in Canada on professional work. We can not imagine that he or his firm would have made the mistake of endorsing the Hawthorne schemes.

DIAMOND mining is in bad repute in New York, where Brazilian ventures have turned out badly. Nevertheless, men associated with the Canadian Mining & Exploration Company have taken an option upon the Arkansas diamond field that has been worked in a small way for the last few years. The geological features, as pointed out some years since by Mr. John C. Branner, at that time state geologist, are entirely favorable. Diamonds of good quality have been found, and since the United States purchases 60 per cent of the world's annual output and there is a heavy tariff on importations, there is every inducement to develop the field if possible. As an excellent illustration of the scale of modern mining, it may be noted that Mr. W. W. Mein, the engineer in charge, proposes to mine and crush 100,000 tons by way of sampling the property. Nothing less, it is felt, will safely determine the average yield of the ground. Mr. Ralph Stokes, at one time by the way our correspondent in South Africa, is in immediate charge of the work. He has recently written most informingly of the Premier diamond mine, in *The Mining Magazine*, and is especially competent to undertake the task.

The Future of Gold Production

Because of its intrinsic worth and the enhancement of interest due to its employment as a standard of value, gold will always remain the metal of premier concern. The basis of the currency of all the chief nations of the world, it functions in a vital, though esoteric, way to influence every phase of life. During recent years world-wide concern has been expressed regarding the steady increase of commodity prices or, to use the stock phrase, 'the high cost of living.' In some quarters the theory is vigorously asserted that this is due to the great increase of gold production in the past decade, and in other quarters it is no less vigorously denied. With these collateral phases of the gold-mining industry, we have no present concern, purposing here to consider present sources of production and what may reasonably be expected to be the course of development in the near future. But we may add in passing that, in our view, the cost of high living is frequently confused with the high cost of living, and the structure of the modern social fabric is so complex that it is highly improbable that there can exist so simple relationship between commodity prices and gold production as some students have been led to believe.

Almost anything can be proved by the judicious use of statistics, and serious blunders may result from indiscriminating tabulations. But when employed with caution, statistics are useful to exhibit relationships and tendencies not otherwise discernible. The table below, showing the annual gold production of the world at three-year intervals since 1906, will be found significant. The figures for 1906 and 1909 are from the report of the Director of the Mint, while those for 1912 are estimates from various sources.

Gold Production of the World, Fine Ounces

	1906.	1909.	1912.
Africa	6,553,484	8,271,575	9,117,600
United States	4,565,333	4,821,701	4,436,400
Australasia	3,985,684	3,435,007	2,671,800
Russia	943,056	1,566,443	1,070,000
Mexico	896,615	1,153,400	1,212,600
India	584,744	501,097	532,000
Canada	581,657	473,591	.....
The Guianas	201,113	191,446	.....
Colombia	105,982	153,826	.....
Total, world	19,366,550	21,982,713	.....

The table makes evident that the rate of increase of production is steadily declining. Production in all the principal regions, with the exception of South Africa and Mexico, is decreasing at a faster rate than can long be compensated by the growing yield of those two countries, the decline in Russia alone more than offsetting the increase in Mexico. Mr. H. C. Hoover, in a recent interview given to the New York *Sun*, discussed at some length the probable future production of gold, reaching the conclusion that the 'first crop' of easily won gold in placers and outcrops has been mainly harvested. Elsewhere in this issue Mr. T. A. Rickard treats in detail of the output during the past year. It would be unprofitable to thresh over old straw, but certain features of the matter may well be emphasized. The table below shows the production of the leading states of the United States for 1905, 1908, and 1911, and may serve to make clear the present situation. The total production of the United States for 1912,

Gold Production of the United States

	1905.	1908.	1911.
California	$19,197,100	$19,329,700	$19,928,500
Colorado	25,701,100	22,871,000	19,138,800
Nevada	5,359,100	11,689,400	18,096,900
Alaska	14,925,600	19,858,800	16,665,200
South Dakota	6,913,900	7,742,200	7,429,500
Utah	5,140,900	3,946,700	4,486,200
Montana	4,889,300	3,160,000	3,649,700
Arizona	2,691,300	2,500,000	3,521,400
Total, U. S.	$88,180,700	$94,560,000	$96,890,000

as estimated by the Director of the Mint, is $91,700,000; a decline of over $5,000,000 as compared with 1911. It will be noticed that the increase in 1908 over 1905 was roughly measured by that shown by Nevada, while 1911 as compared with 1908 shows a total increase of only one-third of that of the same state. The Goldfield Consolidated, which has been such a tremendous producer, is nearing its end, and the detailed figures for 1912 by states, presented on another page, seem to show that the declining output of the Goldfield Consolidated is the chief factor in the lessened yield of the country for the past year. This illustrates an essential feature of gold-mining: the more productive a gold mine is, the faster it is worked out and the sooner it ceases to produce. It is good business policy to 'gouge' a rich mine. The rapid rate of increase in production which the Rand has shown since the close of the Boer war is, however, to be deprecated rather than acclaimed, since it signifies the earlier approach of a period of declining yield. In many of our states, as well as in many of the chief producing countries abroad, the larger part of the output is derived from but a few large mines, the closing down of one of which would serve to more than offset any probable increase in production elsewhere in the area. When mosquitoes die no one misses them; when a Goldfield Consolidated, a Robinson, or a Homestake ceases to produce, a whole new district will scarcely serve to counterbalance the loss.

Over against the certain exhaustion, in course of time, of the mines now productive, may be set the possibility of the discovery of important new mines, the increased yield from present ore reserves through improvements in metallurgical processes, and the possible yield from old tailing. The former has been so thoroughly covered by Mr. Hoover that it is not worth while to do more here than repeat that, now that both the north and south poles have been reached, geographical exploration has fairly thoroughly covered every important part of the earth's surface. This does not mean that everything has been discovered: Cripple Creek lay for years unnoticed, though but a few miles from the capitol of Colorado; but the chances for important discoveries are greatly decreased. It is doubtful if a new Rand or a new Cripple Creek will ever be discovered, though it might be unsafe to assert that no new

source of supply as important as these will ever be developed. The possibilities of Europe, Asia, Africa, and Australasia now appear to have been pretty thoroughly appraised; North and South America are more uncertain. Canada has shown tremendous development in recent years, and the skirmish line of prospectors is steadily forging toward the north from her southern border. Exploration is difficult in a boreal region, prospecting even more so, and it does not seem unreasonable to assume that in her unexplored areas Canada contains potential producing districts of considerable importance. Mining in South America has been hampered by unfavorable climatic conditions in many cases; consequent upon that disadvantage follow a whole train of governing conditions which conspire to increase working cost and decrease profits. It may be urged that the work done on the Panama Canal Zone is prophetic of what will shortly be the order of the day in all tropical countries, but it is easy to obtain a perverted view of the significance of such an achievement. The outlay of $13,000,000 on sanitation in the course of the expenditure of $250,000,000, to June 30, 1911, in the carrying out of a definitely planned enterprise, is one thing; procuring of healthful conditions in mining districts not yet proved to offer great profits, is another matter. Working conditions will assuredly be better as a result of our experience at Panama, but tropic lowlands will not be widely converted into pleasure resorts, for the present at least. It must not be forgotten that the cost of labor is steadily rising the world over, so that future changes will not be all net gain.

The possibilities of metallurgical improvement are similarly difficult to gauge, but do not appear to be great. Improvements will eventuate so long as earnest men continue to put their hearts and brains into their work, but it can scarcely be questioned that the margin is now small and the general manager already has to consider the saving of pennies where dollars were once a possibility. The stage of mechanical and chemical perfection to which the cyanide process has been brought is such that but little more can be gained: the cream has been skimmed, the skim-milk turned into cheese, and not much can be made of the whey. Generalization concerning mining costs is impossible; as cheap work has been done by primitive as by the most refined of modern methods. Nor is there much hope of salvation through the steadily increasing production of base metals, which it may be safely assumed will increase in proportion to man's needs. In the preceding table Utah, the sixth in the list, is the only state where an important part of the total gold production is obtained from base metal ores. In Colorado a little over one per cent of the total gold is obtained from lead ores, and a little less from copper ores; in Nevada two per cent of the total gold is from copper ores and only three-tenths of one per cent from lead ores; while in Montana copper ores contribute one-fifth and in Arizona one-third of the entire output of the yellow metal. Great increases in base metal output would not, therefore, serve to overcome even a slight decline in the yield of the Rand. The past decade has been characterized by a rapidly increasing output of gold, and the conclusion seems unavoidable that the coming decade will be characterized by a slowly declining output; a decline which, so far as can now be foreseen, there is little hope of ever again permanently converting into an increase. Be that as it may, we are firmly of the belief that industry and civilization will continue to progress, and that man will more and more completely subdue the material things of earth to serve his comfort and convenience.

Mexico in Unrest

The chief lesson of the epidemic of revolutions that has undone the pacification of Mexico which Porfirio Diaz had effected, is the need of proper legislation, and rigid enforcement of the laws when made, to prevent participation by our own citizens in such uprisings. The matter may be stated even more pointedly. Penalties of such severity should follow conviction for offenses of this nature as to render it so unsafe for financial interests in the United States to foment and encourage revolutions in foreign countries that capitalists and corporation managers would no more risk playing at the dangerous game of wholesale murder by proxy than they would risk the committing of murder personally to achieve some financial advantage. It is impossible to draw a line between the hiring of an assassin to kill a competitor on Wall Street and the furnishing of money and supplies to a disgruntled political agitator abroad to redden his country with the blood of civil war for the sake of some expected monetary benefits. It is rumored with such circumstantial detail as to produce moral conviction, that within the last twenty years three of the greatest corporations in America have deliberately unchained the dogs of war in countries with which we had concluded solemn treaties of amity and commerce. Venezuela, Nicaragua, and Mexico all have the United States to thank for revolutions which have torn them as only civil wars can do, and that have set them back in their course of development. If our consciences are so seared in respect to international ethics that we remain unmoved and take no effective measures to terminate nefarious proceedings of this kind, we might as well legalize the scheme, jestingly proposed by a shrewd and humorous Yankee in the Argentine, who saw an opportunity for a lucrative business in organizing a war company, ready to hire its soldiers and fleet to the highest bidder, whether revolutionist or representative of a government *de facto*. In all seriousness, the open and ruthless violation of our treaty engagements with Colombia, committed by the Roosevelt administration, was less discreditable than the shallow pretense of observing the neutrality laws which has brought our country into disrepute among all the Latin-American nations during the past two years.

The consequence of the pernicious activities of American citizens, and the connivance of our authorities at revolutionary efforts south of the Rio Grande, has been to let loose the basest passions of brutal men in a long series of rebellions, great and small.

marked by hideous savagery and by frightful destruction of life and property. The Mexican people fully understand the delicate and difficult position in which the Government at Washington has placed itself, and this is part of the cause for the contempt in which they hold Americans in that Republic. The threats from the White House sound even more hollow to the Mexican than they do to our own people. It is embarrassing to admonish a boy not to shoot firecrackers where he may among us, after we have put the firecrackers in his hand.

In addition, the Department of State has stultified itself with a series of absurd communications, both to the Mexican Government and to Americans resident in Mexico. The warnings sent to Americans through consuls made us seem so ridiculous that even the newsboys in the streets hurled insulting epithets at the *gringo* after it became evident that there was neither any intention to protect the lives of those who lingered nor to stop the revolution by intervention. The paltriest of all things is a threat. The stupid communication, indirectly recognizing the belligerency of Orozco, when followed by the announcement that the Madero administration would be held responsible for loss of life and property in any part of Mexico, brought forth a curt retort, so correctly framed in accord with the accepted tenets of international law as to admit of no reply. This added to the contempt of the Mexicans for our country and our people. The preposterous folly of the Administration at Washington in avowing that no intervention would occur gave the Mexicans practically a loose rein. We are not aware of any other country in the world that would commit so childish an indiscretion as to publish its purposes to the winds. The habit of diplomats is to say nothing until the time comes for some decisive action. It is part of the international game to leave the other country in doubt as to what you mean to do. So far as we can see, the present Administration has missed few opportunities to humiliate and endanger those of its citizens who are compelled to reside in Mexico. The last step, taken in the face of a formidable presentation of authenticated acts of violence against Americans, has been to announce that the *status quo* will be suffered to continue until the inauguration of a new president.

The moral effect of this pusillanimous policy has been to encourage revolutionary activity in all parts of Mexico, and to weaken the hands of President Madero. We believe that his sentiment toward our people is generous, and that his intent is to protect the alien to the best of his ability. As the head of the actual Government, he deserves support, but the so-called conciliatory attitude of the American Government makes his course more difficult than it would be if sterner measures were taken. These would arouse the dormant sense of responsibility in the Mexicans, and would tend to consolidate them and make them more careful of American interests, even though they should indulge in a little more rant and bluster. The situation in Mexico is not critical, but it is extremely serious. Three of the most formidable uprisings against the Madero government have been successfully quelled, but the revolutionary disease continues to be sporadic. The army and the corps of *rurales* is wholly inadequate to police the country. The creation of an army of sufficient size to preserve the peace is impossible on account of the lack of funds. Moreover, the army has been recruited in the past mainly from the renegade element, and this stands in the way of enlisting a volunteer force of the better class of citizens, even if money were available for the maintenance and the mobilization of a largely increased force.

The chief weapon needed for the pacification of Mexico, no matter how firm and wise the executive in the chair, is gold. The disturbance of business has been so profound that the industrial life of the country is palsied. The inevitable result has been a tremendous reduction in the revenues. The interest upon the bonded indebtedness of Mexico has been scrupulously paid, showing a proper sense of responsibility as well as a realization of the importance of maintaining the national credit. To do this, and to provide for the interest just falling due, in conjunction with general administration and war expenses, has caused an enormous drain upon the exchequer. One small loan of twenty million pesos was negotiated, through the house of Speyer, upon terms that are reputed to have been onerous; and agents are now abroad for the purpose of borrowing an additional forty million pesos. Meanwhile, the taxes upon tobacco and liquors have been raised, which was the least disturbing means of increasing the revenues. Also a horizontal raise of five per cent upon the customs duties has begun to weigh upon the people, and further elevations of the tariff are proposed. The municipalities, feeling the decrease of income as severely as the Federal Government, have likewise resorted to ingenious means to provide adequate funds. The promises of Madero, made in the flush of a prospering revolution, to reduce the burdens of taxation are impossible of fulfilment. This will augment the popular discontent, and will prove a further menace to political stability. The dilemma of the Administration resembles a snowball which grows as it rolls forward. From mixed motives, deplorable even though the peculiar situation in Mexico may seem on some accounts to warrant the action, President Madero has practised nepotism to a degree that has steadily lessened his popularity.

It is conceivable that several gentlemen, prominent in Mexican affairs, could assume the reins of authority with the approval and confidence of so large a majority of the population as to insure a speedier restoration of normal conditions. The President insists, however, that he will not resign, and that he must have a chance to 'make good.' He certainly has not had a chance to do so, and just as certainly he ought to have the opportunity; but if the present agitation in the country, and the persistent opposition in political circles in the Capital and in the larger cities, continues, he would prove himself a greater patriot by stepping aside, despite the worthiness of his motives and the dreams of reform which he has cherished. If he were given the hearty support of his own countrymen, the agrarian reforms which he proposes would unquestionably

produce a great alleviation of the conditions of the Mexican people, and in the end would benefit all classes. No other aspirant to the presidency is likely to insist upon such measures.

Nevertheless, if the situation does not soon change for the better, he cannot hope to make his projects effective. The situation will not change unless he can adequately finance the Government, including the police arm which is imperative for the re-establishment of order. He cannot finance the Government without the coöperation of foreign financiers. Therefore it is evident that the political stability of Mexico depends, on one side, upon a wise and statesmanlike attitude of the Government of the United States, both on the part of the legislative body and of the executive, and on the other side, it depends upon the willingness of foreign bankers to provide funds under suitable guarantees of national policy as well as of interest and amortization, so as to conserve the vast investments of outside capital which have already been made in that Republic.

Mill Practice in 1912

Busy millmen find it increasingly difficult to follow the latest practice throughout the world, and the annual review of cyanidation during the past year by Mr. Alfred James, which appears on another page of this issue, is correspondingly welcome. To paint the rose is useless, but some of the interesting points touched upon invite further discussion. The successful treatment of rich silver ores calls for the most attention. At Tonopah splendid results are obtained at moderate cost from ores containing 30 ounces of silver and a little gold. The mills at this centre are simple, and no complicated classification is necessary. The MacNamara and Belmont mills were started during the year, and the latter may be cited as an example of unusually good mechanical arrangement. It is making a high extraction at low cost, and in November produced 369,422 ounces, or about 12 tons, of silver bullion from 12,426 tons of ore. The Mexican mill at Virginia City was also started in 1912 and is making a 92 per cent extraction from an ore containing nearly 40 ounces of silver per ton. The application of hot cyanide solutions (about 60°F. at the mortar-boxes and 120°F. in the agitators) has been a great aid in securing higher extractions from these ores. At the Knight's Deep plant, on the Rand, solutions have been heated to 90 or 120°, but apparently this is to secure quicker settlement of slime, as no mention is made of increased extraction.

The 'new' metallurgy of Cobalt, in the mill of the Nipissing company, is of great interest. During November this plant treated 134 tons of a complex silver ore, yielding about 280,000 ounces of silver, or 2090 ounces per ton, with an extraction of 97 per cent. This is done in a tube-mill containing 3¼ tons of ore previously crushed to 20 mesh, 4¼ tons of mercury, 2 tons of 5 per cent cyanide solution, and 6 tons of pebbles. The pulp is filtered on vacuum-filters. This company has also built a stamp-mill for treatment of lower grade ores. Zinc shaving is generally preferred for precipitation of silver from cyanide solutions, but at the new Belmont mill zinc dust gives excellent results. Little has been heard from Mexico during the year, the revolution having interfered with the operation of many mills, but in his recent interesting little book, Mr. Ferdinand McCann gives details of the latest Mexican practice on silver ores.

It would seem that the so-called improved types of roasting furnace to which Mr. James refers are not well adapted to produce a sweet roast, such as is necessary in a dry treatment of sulpho-telluride ores. Perhaps the most interesting roasting plant erected during the year is that at the Goldfield Consolidated mill, which will be described in an early issue of this paper by Mr. J. W. Hutchinson. This plant treats concentrate containing copper, and the method employed should be interesting to our friends at Kalgoorlie, where the roasting and treatment of dry ore and concentrate has reached a high point of efficiency, more especially at the Associated, Kalgurli, Perseverance, and the Horse-Shoe. Rhodesian ores contain antimony, and roasting is being adopted, but if the volatilized antimony oxide condenses and accumulates at the feed end of the furnaces, a modification of the construction will be required.

The gyratory crusher holds the field for coarse crushing in the majority of cases. Where a large capacity is required, this type is the best, but for small plants the jaw crusher is useful and suitable. The use of heavy stamps has its adherents, but greater attention is now paid to such primary crushers as Chilean, Lane, Krupp, and other mills and rolls. The new Buckhorn mill in Nevada will employ rolls, Hardinge mills, and tube-mills. Stage reduction is admitted to give best results, and rolls are now so made that grooving is largely prevented. In tube-milling a number of millmen believe in using ore or rock for crushing, though the efficiency of this is questioned by others, as rough surfaces do not facilitate good impact.

The methods employed in elevating pulp afford an interesting subject for discussion, but practice varies greatly. Bucket elevators work well in many mills, including the Goldfield Consolidated and all the Broken Hill silver-lead mills; centrifugal pumps are considered the best at Tonopah; tailing-wheels at Waihi and two Kalgoorlie plants; plunger pumps at Bendigo and Kalgoorlie; and pumps and wheels on the Rand. Agitation practice is equally varied. Vacuum-filters are being used in many new mills, but at Kalgoorlie the filter-press is doing its usual good work. Labor costs are, however, an objection to it, and probably the practice will have to go under in time. Results from the treatment of low-grade ores at Stratton's Independence, the Treadwell group, Homestake, Wasp No. 2, and the splendid work on ore worth less than $6 per ton at the Perseverance, South Kalgurli, and Associated Northern mills, in Western Australia, are all of the greatest interest. The use of oil-fired assay and clean-up furnaces is increasing, as they afford a particularly convenient means of applying heat. On the whole, the past year was one of great interest to all metallurgists, and further improvement may be confidently expected during the coming year.

Metal Production and Prices in the United States in 1912

UNITED STATES PRODUCTION, 1911 AND 1912

Below are given figures of production for 1911 and estimates for 1912 for coal and the principal metals.

Coal:	1911.	1912.
Bituminous, tons short	396,296,000[1]	480,000,000[4]
Anthracite, tons long.	86,896,000[1]	76,900,000[4]
Pig iron, tons long.... ..	23,649,344[2]	29,700,000[5]
Copper, pounds.....	1,097,232,749[1]	1,249,000,000[4]
Gold, fine ounces.....	4,687,053[3]	4,435,270[3]
Silver, fine ounces.....	60,399,400[3]	62,369,974[3]
Lead, tons short.....	486,976[1]	480,965[4]
Spelter, tons short.....	286,526[1]	338,630[4]
Quicksilver, flasks.....	21,256[1]	23,256[6]

Gold and Silver

The Bureau of the Mint and the United States Geological Survey have issued the following joint statement as the preliminary estimate of the production of gold and silver in the United States during the calendar year 1912. Beside these figures have been placed those for 1911 as given in the final report for the year, issued by the Geological Survey.

Copper

Estimates of production, made by B. S. Butler, of the United States Geological Survey, indicate an output for 1912 in excess of that for any previous year. The total for Lake and blister copper is figured at 1,249,000,000 lb., as against 1,097,232,749 for 1911. Valued at 16c., the output for 1912 was worth nearly $200,000,000, as against $137,154,092 the previous year. Figures published by the Copper Producers' Association show an output of refined copper in the first eleven months equal to 1,429,147,150 lb. The total for the year may be estimated at 1,560,000,000 lb., as against 1,433,875,026 in 1911.

Spelter

The production of primary spelter from domestic ore in 1912 is estimated by C. E. Siebenthal, of the U. S. Geological Survey, at 323,961 short tons and from foreign ore at 14,669 tons, a total of 338,630 tons, worth, at the average St. Louis price, $46,731,000, compared to a total of 286,526 tons in 1911, worth $32,663,964 and made up of 271,621 tons of domestic origin and 14,905 tons of foreign origin.

Lead

According to estimates made by C. E. Siebenthal, of the U. S. Geological Survey, total production of

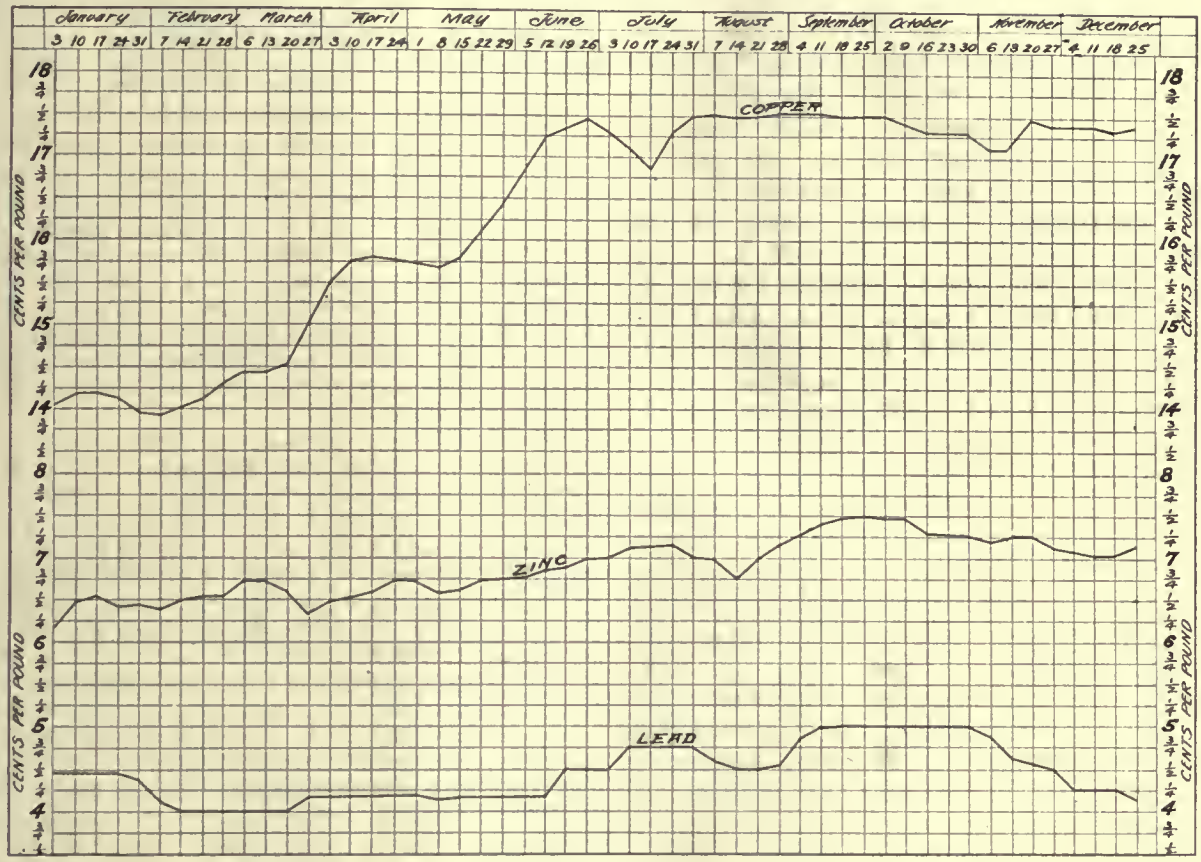
*Maryland and Pennsylvania.

refined lead, desilverized and soft, from domestic and foreign ores in 1912 was approximately 480,965 short tons, worth at the average New York price $43,286,850, compared to 486,976 tons in 1911 and 470,380 tons in 1910. These figures do not include an estimated output of 13,384 tons of antimonial lead.

NEW YORK METAL PRICES

Below is presented in tabular and graphical form a summary of metal prices in New York as quoted weekly in this paper. Following is a discussion of prices by our own correspondent and illuminating comment by E. G. Hothorn.



SILVER

Below is given the average New York quotation, in cents per ounce, of fine silver for the months indicated:

	1911.	1912.		1911.	1912.
Jan.	53.81	56.25	July	52.57	60.67
Feb.	52.23	59.06	Aug.	52.17	61.32
Mch.	52.76	58.37	Sept.	52.43	62.95
Apr.	52.32	59.20	Oct.	53.37	63.16
May	53.31	60.88	Nov.	55.77	62.73
June	53.04	61.29	Dec.	54.85	63.38

COPPER

Daily quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally from 1-5 to 1-4c. per lb. more. Below are average monthly quotations in cents per pound:

	1911.	1912.		1911.	1912.
Jan.	12.29	14.09	July	12.47	17.19
Feb.	12.26	14.08	Aug.	12.41	17.49
Mch.	12.14	14.68	Sept.	12.20	17.56
Apr.	12.02	15.74	Oct.	12.19	17.32
May	11.99	16.03	Nov.	12.61	17.31
June	12.39	17.23	Dec.	13.55	17.37

ZINC

Zinc is quoted as spelter, standard Western brands, and based upon St. Louis or New York delivery. While New York quotations, as a matter of convenience, are commonly used, relatively little spelter actually goes to or comes from New York. The bulk is shipped direct from the plants in the Mississippi Valley to manufacturers, due allowance being made for freight. New York daily quotations are published in this column each week. Below are given averages by months:

	1911.	1912.		1911.	1912.
Jan.	5.45	6.42	July	5.70	7.12
Feb.	5.52	6.50	Aug.	5.95	6.96
Mch.	5.56	6.57	Sept.	5.86	7.45
Apr.	5.40	6.63	Oct.	6.10	7.36
May	5.35	6.68	Nov.	6.38	7.23
June	5.50	6.88	Dec.	6.30	7.09

LEAD

Lead is quoted ordinarily in cents per pound or dollars per hundred pounds delivered at St. Louis or New York. Below are the average New York quotations by months:

	1911.	1912.		1911.	1912.
Jan.	4.48	4.43	July	4.50	4.71
Feb.	4.44	4.03	Aug.	4.50	4.54
Mch.	4.39	4.07	Sept.	4.48	5.00
Apr.	4.41	4.20	Oct.	4.27	5.08
May	4.37	4.20	Nov.	4.30	4.91
June	4.34	4.40	Dec.	4.45	4.20

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average monthly quotations, in dollars, per flask of 75 lb., are given below:

	1911.	1912.		1911.	1912.
Jan.	44.60	43.75	July	48.00	43.00
Feb.	48.40	46.00	Aug.	50.00	42.50
Mch.	52.50	46.00	Sept.	47.50	42.12
Apr.	50.90	42.25	Oct.	46.12	41.50
May	46.50	41.75	Nov.	45.50	41.50
June	46.50	41.30	Dec.	44.50	39.75

TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations average about 5c. per lb. higher. Below are given average monthly New York quotations in cents per pound:

	1911.	1912.		1911.	1912.
Jan.	41.25	42.53	July	42.40	44.25
Feb.	41.61	42.96	Aug.	43.32	45.80
Mch.	40.16	42.58	Sept.	39.75	48.64
Apr.	42.18	43.92	Oct.	41.18	50.01
May	43.11	46.05	Nov.	43.12	49.92
June	44.61	45.76	Dec.	44.65	49.89

EASTERN METAL MARKET REVIEW

[By Our Special Correspondent]

Features of the Year

The Eastern metal market enjoyed its full share of the general prosperity of the country in 1912. Consumption of all the metals was good and December prices, with the exception of those for lead, were substantially higher than those which prevailed at the beginning of the year. The high prices were no impediment to business when activity was at its height, but toward the end of the year when there came a natural tapering off in demand complaint was heard that prices were too high and they undoubtedly caused some restriction of trade. In copper the year reached its climax in August, the production of that month being 145,628,521 lb., or 65,013 gross tons, which broke all records for production. Great as the production in this month was and with stocks on hand at the beginning of the month of 50,280,421 lb., stocks at the end of August were decreased 3,579,047. The year also saw the price of copper just escaping the 18c. level. Tin importations exceeded those of 1911, prices touched and exceeded 50c. per lb. and the demand was fairly steady throughout, one reason being that 1912 was a banner year in the production of tin plates. The year in lead was marked in the last half by rather unusual competition and relatively the lowest price of any of the metals. The consumption of spelter, because of the heavy demands of the brass mills and galvanizers, was particularly good. Antimony was the last metal to respond to the general advance in prices. The year was notable also because the heavy and sustained business was carried on notwithstanding the proposal of early in the spring to reduce the tariff, while the presidential election with its prospect of a change in administration and policies, was practically ignored.

Copper

On January 1, copper stocks were 89,454,695 lb., the lowest in three years. It had been anticipated that the first month would show a further decrease in stocks, but great surprise was manifested when the figures showed that they had diminished no less than 23,174,052 lb. The following table, which lacks December production because the monthly reports of the Copper Producers' Association are not issued until the eighth of each succeeding month, gives the best available idea of copper production, deliveries, and stocks. The decrease noted in June production was ascribed to strikes. It will be noticed that in July production increased over 10,000,000 lb., while stocks increased only 5,945,417. Also that while deliveries were higher in October, they fell short of equalling the increase in production, and that in November there were decreases in both production and deliveries.

November	134,695,440	69,369,795	55,906,550

According to United States Government returns the total imports of foreign copper in the first ten months of the year were 148,000 tons. In 1911 arrivals for the ten months ended with October, were 127,000 tons. The imports for 1912 are expected to prove record breaking, though a falling off in arrivals was noted in November and December. Exports in 1912 will not much exceed, if they equal those in 1911. The total exports in the first eleven months of the year were 298,491 tons, while for the similar period of 1911 they were 299,176 tons. Disturbed financial and business conditions resultant from the Balkan war had much to do with this situation.

Prices.—The year opened with electrolytic copper selling at 14.25c. per lb., New York, and strong at that figure though the domestic demand was moderate. It closed with the metal quoted at over 17c. and the market quiet. Prices, with the customary fluctuations, remained at just over 14c. throughout February, with the feeling improving steadily 14.37½c. was reached at the end of the month. March saw advances to 14.50c. and then higher by stages until 15c. was reached and exceeded, this being the first time in five years that copper had mounted to this level. About this time labor troubles abroad were regarded as a possible cause of curtailment and some harm may have been done. In April the price reached 16c. for electrolytic and in this month advances were announced in the price lists of brass and copper products. About the same price average was maintained throughout May, although toward the end of the month a strong upward movement set in. June brought prices ranging between 17.12½c. and 17.62½c. and a continuance of the good market, although in this month strike troubles at the works of the Standard Underground Cable Co. at Perth Amboy, N. J., and the National Cable & Conduit Co. at Hastings, N. Y., tended to cut down the consumption. It was believed, however, that this cut was offset by similar troubles at the Baltimore, Md., and Laurel Hill, N. Y., refineries of the A. S. & R. and Nichols Chemical Co., all of which were short-lived. The price range in July for electrolytic was between 17 and 17.62½c. with the demand continuing good. In August the metal went a few points higher and the large consumption and production already referred to took place. September prices were at or near the peg price of 17.75c. fixed by the copper producers as were those of October. In the latter part of the month well founded fears developed as to the effects of the Balkan war on European demand. Prices, though holding fairly well, showed a weaker tendency in November, in which month the exports were the smallest in two years. In December further reductions in price were made, copper selling down to 17.37½c. and even lower for small lots, and demand being quieter at home and abroad. As to the foreign market, much depended at this time on the outcome of the peace negotiations in London for the settlement of the war between Turkey and the Balkan allies.

The first week of December was extremely quiet and in the absence of any demand worthy of note prices sagged to 17.37½c. and reports were current of small sales at still lower prices. The copper producers' statement, out December 8, for November was favorably received by sellers as the increase in stocks (9,419,095) was less than had been expected. The second week of the month saw a still further softening of prices, including those for Lake copper, which had long stood steadfast. Then came a decided

improvement in demand and prices and more sales were made than in some time past. There were good transactions in electrolytic at 17.62½c. delivered Connecticut points cash 30 days, and small parcels were taken on the same basis at 17.50 cash f. o. b. N. Y. The end of the month found the metal firm at around 17.62c. cash N. Y. for Lake and 17.50 cash N. Y. for electrolytic, and there were no indications of a declining market. On the contrary as the year drew to a close a good buying movement was expected momentarily. An explanation of an apparent discrepancy between the November export figures of the copper producers' statement and those of the United States government is that the government figures at the end of November consisted only of those returns which had been received at the customs house, whereas those of the producers included copper which was aboard ship but which had not left the port. It was alleged in some directions that the producers had included December copper in their November exports, but this allegation proved to be without foundation. Exports for December to the 27th were 23,946 tons.

Tin

The most conspicuous feature in pig tin was the fact that prices advanced in the year to 50c. and over and though they sagged toward the end of the year they were not far away from the 50c. level from the last part of September on, and exceeded 50c. in December. The importations of the metal were large, totaling 45,515 tons between January 1 and December 1. Total deliveries into consumption in the first eleven months of 1912 were 45,450 tons as against 40,600 tons in the same period of 1911. The total visible supply November 30, 1912, was 12,348 tons as against 16,630 tons November 30, 1911, or 4282 tons less than in 1911 at the time named.

The year opened with tin selling at about 44.25c. and irregular, but a good demand soon developed. Prices were subject at times to violent fluctuations as a result of English price variations ascribed to manipulations in London, the controlling centre of tin. On January 3, for example, spot tin broke £10 in London with resultant effects in the New York market. In February tin was up to 44c. again. In this month a standard form of tin contract was adopted by the New York Metal Exchange in the endeavor to extend and broaden trading on the floor of this institution. The new contract has undoubtedly had a salutary effect, although the bulk of tin transactions are still outside of the Exchange. The price range in March was between 42.15c. and 43.37½c. and in April between 43c. and 44.75c. An unusual feature of the latter month was that Banca tin for prompt shipment was selling at 1c. per lb. higher than Straits, and Banca usually is a second choice. The range in May was 44.75c. to 46.12½c., and in June the price went to 48.50c. Both in May and June the big shipping strike in London caused trouble by delaying shipments, a difficulty which finally was surmounted by means of shipments from Holland ports. Prices in July fluctuated between 43.62½c. and 46c., and in this month it was currently reported that the United States Steel Corporation, the largest user of the metal in the United States, had bought heavily in Singapore, London, and New York. August prices were 45.12½c. to 46.25. It was on September 20 that 50c. was reached and before the month closed, the price mounted to 50.10c. Prior to it reaching 50c., the Steel Corporation was reported a heavy buyer. In October the price touched 50.40c. and in November and December prices hovered between 49c. and 50c., a lower tendency setting in at the end of the year. The dates of the six bi-monthly Banca auction sales to be held in Holland in 1913 have been fixed as follows: January 29, March 27, May 28, July 30, September 25, and November 27. The sales will amount to about 14,880 tons or about 2480 tons for each auction.

Spelter

Spelter was quoted at 6.35c. to 6.70c. in January in which month there was considerable talk of the scarcity of the metal. In February the price did not reach much higher limits and there was continued reports of scarcity of some brands. In March responding to the better demand the price went to over 7c., dropping again to 6.75c. and lower in April. In May and the early part of June prices were about 6.80c. to 6.90. It was in the latter month that the real upward movement began and 7.15c. was reached by July 1. In this month prices went to 7.35c. and the high cost of ore was mentioned as a cause. Prices in August hovered between 7.10c. and 7.25c., in September between 7.25c. and 7.65c., and between 7.50c. and 7.65c. in October. Reports were current in October of the importation of foreign spelter, while in early November the U. S. Steel Corporation imported 2000 tons at 1c. under domestic prices to be exported in product form with the advantage of the draw-back duty. In November 7.50c. was the average price, followed in December by subsidence in the demand and in prime western down to 7.30c. and lower.

Lead

The year began with lead quiet at 4.45c. New York, which price it held to the end of the month when there was a drop to 4c., where it remained through February and half of March. It was a price generally condemned as too low and there was relief on the part of sellers when 4.20c. was reached. The latter price prevailed throughout April, May, and into the early part of June, when the American S. & R. Co. sent its price up to 4.50c. Early in July there was a similar advance of 25 points to 4.75c., which the independents did not entirely follow. Early in August the largest interest lowered its price to 4.50c., but at the end of the month made an advance to 4.65c. Then came in quick succession advances to 4.85c. and then to 5.10c., the latter price prevailing throughout September. The rise to 5.10c. was due to the high prices prevailing for lead in London. English lead was quoted at £25, equal to 5.02c. New York and it was possible to buy American lead in New York at 4.85c., ship it abroad, and sell at a profit. In the latter part of October the prices of the independents dropped to 5.05 and this seemed to be the beginning of a period of keen competition in the metal. A factor in the situation was the new International S. & R. Co. Prices hereafter followed a declining tendency. The largest interest in early November reduced the price to 4.75c. and subsequently within the month quotations declined to 4.50c. Early in December the A. S. & R. Co. again reduced its price to 4.35c., but this was cut by independents to 4.32½c. and lower and the feeling became unsettled.

Antimony

Antimony was selling at 7.75c. to 7.87½c. for Cookson's, 7.60c. to 7.70c. for Hallett's and 7c. to 7.12½c. for Hungarian and Chinese grades at the beginning of 1912, and in the closing month at 9.87½c. to 10.25c. for Cookson's, 9.50c. to 9.75c. for Hallett's, and 9c. to 9.25c. for Hungarian and Chinese. The most substantial advances in prices came in the last quarter of the year, following the high prices of other metals. In January there was reported a scarcity of Hallett's, and before the month was over that brand was selling at 7.55c., while Cookson's was quoted lower at 7.37½c., thereby reversing usual conditions. In February prices were lower at 7.25c. for Cookson's, and 7.50c. for Hallett's, while in March much the same conditions prevailed, though Halletts was lower. In April there was a betterment, with Cookson's selling at 8c. and Hallett's at 7.62½c. Not much of interest occurred until early August when prices advanced out of sympathy with the other metals, and Cookson's touched 8.60c., Hallett's 7.87½c., and Hungarian and Chinese grades 7.75c. In October there was greater activity in the demand and prices advanced to the top notch of 10.50c. for Cookson5s, 9.75c. for Hallett's, and 9.37½c. to 9.50c. for Hungarian and Chinese. Since that time prices have sagged and shown no substantial recoveries. During December certain speculative influences unsettled the market and caused the import cost to be undersold. It is reported that more than one speculator who bought on the rise of the market is now trying to unload, but finds consumers pretty well supplied and the demand slackening. At the end of the month Cookson's was quoted at 9.87½c. per lb., Hallett's at 9.50c., and Chinese and Hungarian grades at 9 cents.

Aluminum

Aluminum in ton lots for re-melting, 98-99% pure, is now quoted at 26.50c. to 27.50c. per lb., and its position is strong. Early in 1912 when the price was in the neighborhood of 19c., a combine was formed abroad which embraced most of the foreign makers. Subsequently prices advanced on the other side and prices have followed. The sale of foreign aluminum contracted so far as the number of American sellers were concerned. Those who did have stocks of the metal sold advantageously in the narrower market. Prices advanced steadily with a demand so great that American producers could not keep pace with it and in some cases consumers were led to recourse to other metals, though the latter might not be so satisfactory. In other cases, metal was bought at high prices. Recently there has been talk of 'outside' producers in the European field, but nothing definite has appeared. Prices promise to keep up. At Whitney, N. C., the Southern Aluminum Co., is now erecting a plant which in the course of a few months is expected to produce at a rate of 25,000 tons per year. The company which is a New York corporation, backed by French capital, is identified with interests associated with L'Aluminum Francaise, of Paris. Its product is needed and should find a ready market.

METAL PRICES IN 1912

By E. G. Hothorn

Copper

Without following the monthly fluctuations and revamping the changes of the market during the year, it is worth while to point out that the most important development was the apparent realization on the part of large producers that the policy of selling copper around 12½c. was unwise. It is generally understood that the natural resources of the country have been heavily drawn upon as far as metals and especially copper is concerned, and this has caused a reversal of the former anxiety to sell copper regardless of price. Increasing demand from Europe and appreciation that stocks in the hands of consumers had decreased during preceding years, caused a steady advance. Speculators took advantage of the opportunity to push the market energetically, and as usual the swing carried prices to figures which would have been considered unwarranted a year ago. Finally demand became so urgent that repetition of the scarcity which marked the early months of 1906 and 1907 was feared. But for the Balkan war and the consequent financial tension in Europe, prices would probably have risen to 20c. or higher. Recent developments have had a salutary effect on such bullish enthusiasm. A feeling of pessimism is sweeping over the trade due to fears that the present market has again been artificially pegged, and that another collapse is due. Against this theory a number of weighty reasons present themselves: First, the steadily increasing demand per capita for copper in Europe; second, the prospect of a larger demand in the United States which so far has not been affected by the genuine boom, the demands to date representing only the present needs of the country; third, realization that new copper production of any consequence is far off, and that the output has probably reached its maximum, many mines being near the time when decreases rather than increases may be expected. While, therefore, the year does not close with fireworks which in America are alone considered valid indications of good times, the foundation is sound, and only a period of depression in Europe as well as in this country can affect the market disastrously. It may be argued that the advance from 12½ to 17¾c. was not justified, and that it would have been safer to keep prices around 15 or 16c. However, such theories do not take into consideration that in this country troughs of depression and frothy billows of enthusiasm regularly alternate, due to lack of poise in commercial affairs on the part of our people.

Pig Lead

While in other metals the course of the market has been in harmony with the general revival of trade, lead has undergone so much manipulation that buyers have been and are still floundering in the dark as to the real reasons for the depression which took place in February and March, the rapid advance of the summer and the subsequent still more rapid decline. All signs point to a large increase in demand for paint, lead-covered cables, and other uses, while production must have remained practically stationary. Though actual figures are not as yet available, it is well known that no new lead mines of consequence have been found in the United States during the last decade. The European price at one time during the year showed an increase of 80% compared with the low of 1907. The advance in other metals, notably iron, copper, spelter, and tin appears warranted and has been sustained, while developments in lead would imply that its advance was a matter of manipulation. Though I do not agree with this argument I feel convinced that stocks of lead have decreased during the year, and that the advance was forced on the leading group by the large demand. Consumers, however, are mystified and so pessimistic that purchases on their part are confined to the barest necessities. During the latter part of the year a new refinery which has been accumulating bullion for twelve months or more forced its output on a market which was unfavorably affected by fears of tariff reduction and disturbed conditions in general. It is useless to point out that lead is relatively and actually the cheapest of all metals. It is more than likely that no life can be expected until the policy of the new administration is clearly defined. On the other hand, I believe that tariff or no tariff lead is bound to feel the rapidly increasing world-wide demand for all metals and that production will remain stationary. The annual increase in United States output during last four years amounts to 60,000 tons, derived chiefly from Missouri. Notwithstanding this, however, the market closes flat, with prospects of still lower prices unless sentiment changes materially for the better. Europe reports that exceptionally large orders from Austria and Russia promise to offset a possible decrease of the German and English demand. The increase in German consumption this year will be 20% over the previous year; a rate that can hardly continue without interruption. No view of the market would be complete which did not take into consideration a decrease in lead production caused by the political troubles in Mexico and labor difficulties in Spain.

Spelter

The scarcity of this metal, which had become a matter of public knowledge at the end of 1911, became accentuated with each succeeding month of 1912, causing an unprecedented high level of prices. But for relief by importations from Europe, supplies would have run short. The plants making galvanized materials were better employed than ever before, while the demand for sheet zinc and brass showed an appreciable increase compared with the year before. I feel satisfied that statistics will show a substantial increase in production though shortage of gas interfered materially with the output. On the other hand I am convinced that when consumption becomes known, a larger ratio of increase will be shown than in any other metal. I figure that consumption of other metals has been about 10% larger than the year before, but spelter consumption must have increased fully 15%. The reasons are not only a large demand for galvanized sheets and wire in the United States, but also a heavy export demand. Higher prices of shingles and fence rails create automatically a larger demand for galvanized roofing and fencing. In this connection it is worthy of note that the European price of spelter has ruled at much higher levels than before. Exhaustion of zinc mines in other countries, notably Australia, foreshadows the time when Europe may have to supplement its supplies by drawing from the United States, where, fortunately, new districts promise to compensate the stationary supply from Joplin. At the close of the year none of the hesitancy to purchase, which affects other metals, is perceptible in zinc, and for the new year a large business is in sight.

Tin

During the past year tin has maintained its reputation as one of the most erratic and fluctuating commodities in the world. The extreme range in London has been from about £188 (40⅜c.) to £235 (51c.). The production of this metal is only about 120,000 tons per annum, of which in the neighborhood of 60,000 tons come from the Straits and the remainder from miscellaneous sources, principally the Dutch East Indies, with scattering quantities from Australia, China, South Africa, and Cornwall. America this year has used in the neighborhood of 50,000 tons, which marked a large increase over the previous high record, and in addition European deliveries have been larger. This simultaneous increase in demand all over the world has put a severe strain on the market, reducing supplies fully 5000 tons. This constitutes a reduction of 33⅓%. At the beginning of the year the visible supply was about 16,000 and at the end about 11,000 tons—equal to a little more than one month's supply. This close balance between supply and demand makes the market susceptible to manipulation, yet in a metal which is so important to the world industrially, and the uses of which are so multifarious and diverse, it is difficult to say to what extent present high prices are due to manipulation, and to what extent they are entirely legitimate. High as tin is at the present time, in periods of corners it has been even higher without apparently checking demand in the least. The price at which its use will be curtailed or the production expanded, has yet to be discovered, and best opinion is that should business both here and abroad continue upon the scale of 1912 and no new supplies be forthcoming, still higher prices than those now existing will be witnessed.

Platinum

[St. Petersburg Correspondence]

The world's supply of platinum continues to come mainly from Russia, and recent high prices have produced important changes in the old mining districts. For reasons which it is impossible to define, the price, in spite of a limited foreign demand, remains in the immediate neighborhood of the record level—a trifle under it, but no more. This has continued now for many months. Every piece of ground that would produce platinum has been worked, so far as is known. Placers previously considered of little value have been made profitable this year, and large houses that were content to work on a comfortably limited scale have extended their operations and are working, with and without dredges, on a scale hitherto unknown. The production cannot be stated. The metal is held in such a manner as to constitute a permanent enigma. Those who make it their business to speculate in platinum are content, either for their own account or perhaps on behalf of some one behind the scenes, to pay even higher prices to tributers than the official quotation on the Ekaterinburg metal exchange. This is continuously ascribed to speculators, but it may turn out that these speculators are the agents of foreign houses.

Meantime the great platinum question, namely, the regulation of the industry by the Russian Government, hangs fire. The principle, as is known, has been accepted by the Duma, but the act has several phases to go through before it becomes a law. Should it do so, which is more than probable, it is hard to see how the extension of foreign buying of existing stocks in Russia will tally with the interests of buyers, for it has never been suggested that the price at which platinum should be pawned with the Imperial Bank should be on the level of the present price quoted. An interesting development in connection with this is the step taken by the well known Tentelieff Chemical Works, and announced some time ago, in the formation of a platinum section of the works, which is equipped to deal with platinum almost as completely as is western Europe. It will be remembered that the crucial question in connection with the disposition of platinum has always been the capacity of the Russians to refine it. The Tentelieff company is a strong one—at least it is believed to be—and is presumably capable of spending the money to equip an efficient platinum laboratory. As the total quantity to be handled is by no means large, the step taken by this company might have the effect not only of disappointing the foreigners, but of materially modifying the results of the proposed law. From every point of view, this year was a great success financially, whatever it may be quantitatively. Incidentally, a feature of the metal exchange operations at Ekaterinburg has been the uniform absence of osmiridium.

The Bureau of Mines and the West

By J. A. Holmes

The Bureau of Mines is now endeavoring to expend wisely an initial appropriation of $50,000 granted by Congress a few months ago, and it is asking Congress at its present session to appropriate a still larger amount for investigations looking to the betterment of mining in the Western states. The Western mining men labored so long and so earnestly for national recognition and aid for the mining industry, that the present Director of the Bureau of Mines deems it eminently proper to keep in close touch with them concerning whatever investigations may be authorized by Congress and conducted by the Bureau relative to those phases of the mining industry in which the West is interested. And it may be appropriate at this time to set forth briefly the general prineiples upon which is based the policy of the Bureau of Mines.

1. It is not intended that the Bureau of Mines should undertake work in the interest of any private party; nor that its employees should compete with the private mining and metallurgical engineers and chemists of the country in doing work which the latter are prepared to do, and should be employed to do.

2. The Bureau of Mines has been established in recognition of the fact that there is in the mining, as there is in the agricultural industry of the country, a public welfare; and the Bureau's chief function is to conduct such inquiries and investigations as are likely to prove beneficial to the mining industry, and therefore to the general public.

The employees of the Bureau of Mines recognize fully the importance of the work that is being done by the private mining and metallurgical engineers, by the private assay laboratories and testing stations, and by the mining schools of the country. To these agencies the mining industry is indebted beyond all estimate for the progress it has made. It is believed and desired that the work of the Bureau of Mines, instead of interfering with, will increase and strengthen the work that is being done and that must be done hereafter by all these agencies. Such has been the result of the work of the Bureau of Mines (and of the Technologic Branch of the Geological Survey which preceded it) in relation to the fuel industries of the country; and it is believed that such will be the result of the Bureau's investigations in relation to the metal-mining industries. What the present management of the Bureau of Mines believes in, and most desires, is coöperation and not competition between its work and that of the other agencies that are laboring for the upbuilding of the mining industry. By supplying the Bureau with information concerning improvements with which they are personally familiar, and by giving it the benefit of their suggestions and advice—all of which will be welcome—the mining and metallurgical engineers and chemists of the country can render a most important service; and whenever, in turn, the employees of the Bureau of Mines can render any services that will be helpful to the industry and in keeping with its duty as a public institution, they will most gladly render such services.

Under its present authorization, the Bureau is concerned first of all with matters pertaining to safety and health conditions in mines and metallurgical plants. Next to these in importance are the problems that relate to waste or losses in the mining and treatment and use of mineral resources; following that various other problems having to do with the general development and wise use of these resources. The words "safety and efficiency" in mining and metallurgy serve as a good motto for the work of the Federal Government in relation to mining. As Director of the Bureau of Mines, I will be glad to receive from local mining and metallurgical engineers in the different mining districts information and suggestions.

Some of the subjects concerning which information and suggestions are desired especially, for the reason that they are already being studied by the engineers of the Bureau, are the following: (1) How to lessen the number of accidents in metal mining —the latest data available show the fatal accidents in metal mines for 1911 to be about 4 deaths for each 1000 men employed, which is a larger death rate than in coal mining, where in 1911 the ratio was 3.8 deaths for each 1000 men employed; (2) health conditions in metal mines and how these may be improved; (3) data concerning the need of better ventilation in metal mines, and the most efficient and economical methods of accomplishing the needed changes; (4) what explosives are being used in metal mines, and suggestions looking to greater safety and efficiency in their use; (5) examples and amount of waste or losses in different mining and metallurgical operations, and suggestions as to how such waste or losses can be reduced; (6) the success or failure attending the use of any new or special equipment or progress in the mining or treatment of ores or minerals under different conditions; (7) the nature and extent and methods of studying low-grade ores with special reference to the possibility of their successful treatment, and the same relative to ores carrying the rarer metals or rare minerals substances.

It is hoped that the work of the new year will bring the Bureau of Mines and the mining and metallurgical engineers of the West into closer coöperation relative to these and other mining problems, even incomplete solution of which cannot fail to advance the industry. The effort to secure federal recognition and aid for the mining industry has thus far met with but limited success. Full success will only come after further united effort. Even after this has been attained in degree proportionate to that given to agriculture, there will yet be need of research work by all available agencies found in the federal and state governments, mining schools, and private laboratories working in behalf of private corporations.

The Year in the London Mining Market

By T. A. Rickard

Introductory.—The year just closed has been full of interest, as is inevitable in a business so subject to the chances and changes of fortune. Whatever the drawbacks, it must be allowed that the industry, the business, or the game, as mining variously presents itself, is never dull. It is synonymous with risk as with gain, with vicissitudes as with luck, with trickery as with skill. Of all of these aspects we have had plenty of examples during the past twelve months.

Despite the alarums and excursions of war, the mining department of the Stock Exchange has gained in strength. Indeed, it has become obvious

that the real business of winning the metals is but little affected by organized murder in Tripoli or the Balkans, for the industry is largely centred in regions less subject to these outbreaks of barbarism. In one important mineral region, it is true, the swing of the pick has been stayed by the flash of the sword; yet even in Mexico the operations of the big mines have scarcely been curtailed, and if new ventures have been held in abeyance it is with the justifiable hope that an era of disorder is coming to a close.

Among the dramatic episodes of 1912 I must chronicle the culmination of two fiascos, the East Rand Proprietary and the Anglo-Continental. Both have been thoroughly ventilated in the press, so that it may be hoped the shock to public confidence may have been compensated by the salutary lesson offered to all but the incurably careless. The East Rand affair showed that big mines need big men to manage them, and that the superintendent of such a mine should be a man capable of telling his directors to go to hell if they ask him to subordinate his operations to the share-market. The Anglo-Continental proved that fairy tales are believed even by grown-ups and that old ways are not obsolete. The acceptance of wild reports cabled by nobodies, the delay in publishing those that recognized realities, and the subordination of mining operations to market manipulation recall some of the worst scandals of the past. It will all have been worth while if the experience impresses the public with one of the fundamentals of the business, namely, that the only opinion on a mine worthy of acceptance is that of a thoroughly competent engineer.

Transvaal.—The digging of gold ore is maintained on an undiminished scale. The Rand is still the premier goldfield of the world, and continues to make new records of production. The total yield for 1912 is estimated at £38,750,000, which is £3,710,000 more than the previous highest, in 1911. I believe the industry to be at its zenith. Production, it is true, still shows signs of expansion, but the profit, the basic purpose of mining, is decreasing, as the following statistics indicate.

Year.	Tons.	Yield per ton, shillings	Cost per ton, shillings	Profit per ton, shillings	Total profit.
1909	20,543,759	28.9	17.0	11.5	£11,794,376
1910	21,432,541	28.5	17.6	10.5	11,216,105
1911	23,888,260	27.6	18.0	9.6	11,414,863
*1912	26,100,000	28.5	18.9	9.6	12,300,000

*Estimated.

But these official statistics cannot be taken at their face value, since 'profit' is not the net resultant gain to shareholders, but an intermediate stage of bookkeeping. Of the 'profit' only 68% is now distributable in dividends, as compared with 75% available a few years ago, so that a supposed profit of £12,000,000 in 1912 actually means less gain to the shareholders than £11,000,000 of phantasmal profit in 1911.

While the average yield has been slightly increased lately, this must be taken in the light of the fact that a system of selective stoping has augmented the gold-contents of the ore from several important mines at the expense of their longevity. For many years the public, and some of the operators themselves, were fooled into a false sense of prosperity by a decrease in the cost per ton, consequent upon the extraction of gold-bearing rock that was so poor as not to yield a profit—only tonnage. Rock that was ore, theatrically speaking, was counted in the reserves. That fallacy was bound to be exposed. With the exposure came a reversion to an elementary principle of mining, namely, to exploit only

the rock that yields a profit. This, being translated, means selective stoping, the rejection of waste, and the diminution of the total tonnage extractable. Hence the present period of improved productivity is won not at the expense of realities but at the cost of the optimistic records made at an earlier period. Even today some of the companies include rock assaying 1.7 dwt. and 2 dwt. as 'unpayable ore,' a sickly phrase which is nothing if not delusive in a district where the operating cost is 4 dwt., and the total cost fully 5 dwt. per ton, without probability of a radical decrease in the near future.

Besides the declining yield, partly due to depth, the mines have been handicapped by scarcity of labor. This was felt acutely during the summer, but was mitigated later by the seasonal migration of natives. Further hindrance to production from this cause is likely to be alleviated by the closing of exhausted mines and by the cessation of destructive competition for labor between the principal groups of controlling operators. While the question of native labor is likely, therefore, to occasion less anxiety, that of white labor is beginning to be serious. In the earnest effort to cheapen mining by the increasing use of small stoping-drills, it has become necessary to employ a larger proportion of skilled white workers. These are beginning to manifest signs of organized unrest, which is sure, sooner or later, to take the form of a strike. Another effect of the machine-drill is to make the dust that is the immediate cause of phthisis, a disease now pitifully prevalent in the mines at Johannesburg. Much has been done to combat this disease and to compensate those who suffer from it. Ventilation, housing, and feeding, that is, the systematic care of the human machine, are receiving closer attention. Such measures may counteract the insidious effort of the labor-agitator, but the position is always delicate and precarious from an economic standpoint.

Two other factors apparent to the detached onlooker should be mentioned. One is the gradual withdrawal of certain big groups or financial houses from Rand mining, in consequence of the lessening opportunity for the flamboyant finance that accompanies an era of expansion. The chances for making money easily and quickly are nothing like they used to be. Scope for new enterprise is dwindling. The public is not so keen to come into the Kaffir game. And on top of this is the dearth of men built on a big scale, such as those who developed the mining industry of the Rand to its colossal proportions. Alfred Beit, Cecil Rhodes, and Herrmann Eckstein are no more; Louis J. Seymour is dead; engineers like H. C. Perkins, Hennen Jennings, George Webber, J. R. Williams, and J. Harry Johns have left the Rand. Not only has the industry lost this motive power, but the operators now dominant spend too much time in talking politics at Cape Town and in squeezing knighthoods out of the ministry at Westminster.

Among many signs of decadence, one fact is full of promise, namely, the development of the Far Eastern end of the Witwatersrand. This part of the great goldfield is marked first by a pronounced break in the outcrop and then by a sweeping curve southward outlining a synclinal basin that encloses a large area in which drilling and shaft-sinking have proved enormous reserves of valuable ore. The Van Ryn, Kleinfontein, and the two Modderfontein mines were among the first to win prominence for this extension of the Main Reef series. During 1912 the Brakpan reached a highly productive stage, while the Modderfontein Deep and Government Areas have given evidence of further potentialities. In this locality the flatness of the dip (5 to 6°) is such that it is practicable for a shaft 3500 to 4000 ft. deep vertically to cut the lode at a distance of three miles from the outcrop and to employ a system of endless-rope haulage highly favorable to cheap tramming. At the other end of the goldfield, the West Rand Consolidated has obtained an encouraging yield from the so-called Battery Reef series, a subordinate member of the gold-bearing conglomerates. This is likely to encourage another effort to explore the West Rand Estates, where an excessive inflow of water formerly stopped prospecting. Again, in the Central Rand a few mines have obtained better results, partly by selective stoping and partly by a genuine improvement in the orebodies. Of the big amalgamations, the East Rand Proprietary has been depreciated by bad management and unreasonable optimism. The Crown Mines, however, while also disappointing as regards immediate results, is in an improving position. Among the great mines of the world may now be included the Crown Mines, the New Modderfontein, and the Brakpan.

I have devoted a large part of my space to the Rand, for apart from its preëminence as a source of the world's gold supply, its varying fortunes profoundly affect the London market and the support that the British public gives to mining in general.

Rhodesia.—This part of the world produces £2,800,000 worth of gold annually, but it looms large in the speculative firmament. If the purpose of mining is to furnish counters for a dishonest gamble, then Rhodesia is a great mining centre. Truly, that fine country, christened after a man of noble proportions, has illustrated repeatedly how mining can be made a mixture of gaming and vaudeville, an African casino where belted knights of recent creation and reckless schemers of the most ancient type can disport themselves profitably before a deluded public. The present year began with a new shuffling of the cards, and a fresh call from the croupiers. But the game has lost its savor; it is not good enough: the public is weary of the hippodrome, that Rhodesian *petits chevaux* in which the racers are controlled by strings no longer invisible.

Mining in Rhodesia as conducted by London companies is a pitiful business. For three years I have watched it, at first without prejudice, then with surprise, and finally with disgust. The most regrettable feature is the fact that reputable engineers have lent themselves to the *opera bouffe*, and some of them appear not only to be lent, but actually sold to the *entrepreneurs* who finance the performance.

During 1912 a breathless effort was made to boom the Rhodesian market, but it failed utterly. You can fool some of the people some of the time. Two or three reckless operators subventioned the hireling

press, their dummies on important directorates tried to talk big, working capital was employed in buying the shares of affiliated companies, cryptic reports of discredited engineers were issued, but it all fell flat. I hope such methods may always fail. I hope that only legitimate methods may win public approval, and that only straight dealing may commend itself to those on whom, in the last resort, the financial groups depend for support.

A glance at the Rhodesian share-list shows the severe drop in quotations. It also serves as a reminder that the country possesses half-a-dozen rich gold mines, all of which have been kited to a market valuation that was bound to collapse sooner or later. Rhodesia, more than any other mining region, reminds me that more money is lost over rich mines than over poor ones, by exaggerating the value of the rich mine to many times its real value, which is a fraction of that engulfed by the poor prospect. Among the notable properties are the Shamva, Globe & Phoenix, Giant, Eldorado Banket, Lonely Reef, Eileen Alannah, and Cam & Motor. The last two are just coming to fruition. The Lonely and Eldorado are rich mines, both of which, however, must perform miracles to justify their recent appraisal. The Giant orebody is cut off by a dike: an unpleasant geologic accident known officially long before the shareholders heard about it. The Shamva is a big mass of low-grade ore from which a profit of barely £1,000,000 is assured, although the market price of the property has been to £2,875,000. Even the most promising of the younger mines, on which Rhodesia must depend for a revival, have already been overvalued in consequence of a mixture of ignorance and chicanery. The outlook is bad. The story of 1913 will be unpleasant.

Close to Rhodesia, but in the Congo Free State, is the celebrated Tanganyika Concessions, once the menace of the copper market. Was it not said three years ago that from Tanganyika would go "within three years" 60,000 to 90,000 tons of copper per year to London at a total cost of £25 per ton? That reads like a pipe-dream of a summer day. Even now the metallurgical problem at Katanga is a matter for experiment, and copper smelting is being conducted on a petty scale. Selected ore is being treated at a total cost that, as far as can be ascertained, is fully £50 per ton of refined copper delivered on the market. An awakening to realities is becoming apparent. With it is coming more serious attention to the difficulties incidental to all big copper enterprises, particularly in a tropical region several thousand miles from anywhere.

West Africa.—Here also the year has seen disillusionment. But a distinction must be made between the Gold Coast and Nigeria. The first is an old mining region and the scene of several successive periods of activity. The latest boom was in 1909, at which time it was fondly expected that "another Rand" had been uncovered along the Tarkwa ranges, and that another goldfield of the first rank would be developed in the African jungle. Here again the promoter and financier outstripped the engineer, but, it must be confessed, not without encouragement from the technical man. It was not that the gold content of the ore was exaggerated, although that was done; or that the banket proved patchy, for that was no man's fault; but the basic cause of economic error was the miscalculation of the total cost of mining. Comparisons were made with the Rand and other established centres of industry. The debilitating climate, the inefficient and insufficient labor, the unsympathetic colonial government, the unusual expenses of administration—these, and other items, were overlooked or disregarded. The time for a reckoning has come. It is now known that the total cost of making dividends is nearer £2 per ton than the £1 per ton confidently asserted three years ago. Several amalgamations and liquidations have occurred in 1912. The number of shares standing at par today is pitiful. Of these, the Prestea has been the subject of an administrative bungle that was ludicrous in its effrontery. This is a splendid vein of gold-bearing quartz and could be regarded as the making of a fine mine if the cost of operations had not been sadly underestimated and the management lamentably subordinated to market tactics. The one bright spot in the jungle is the Ashanti Goldfields, which has made a splendid showing this year, reducing the total cost from 43s. to 35s. per ton, and earning a profit of £214,425. It is also to be noted that three dredging companies are struggling under adverse conditions amid the tropical tangle of roots and floods to dig gold out of the river-beds; not without success, and with increasing skill, as well as hopefulness. The production of gold from West Africa in 1912 is estimated at £1,500,000.

The tin districts of Northern Nigeria have surpassed the Gold Coast this year as regards public interest. It has been a gay time for syndicates and schemers operating on the Bauchi and Kano tablelands. Early in the year the boom reached its zenith, puffed into bulkiness by the success of the Rayfield syndicate, the Nigerian Tin Corporation, and the Northern Nigeria Mining & Exploration company, all of them capitalized for small sums and doing a roaring business, not so much in tin-mining as in the printing of scrip for an eager market. By this I do not mean that the Rayfield, for example, did not find rich alluvium and produce tin profitably, but it is a fact that the 'calabashing' or panning of tin gravel by natives on tribute soon became only a detail in a picture the larger part of which was filled by Throgmorton street. The public bit greedily. Share speculation culminated soon after the Anglo-Continental Mines Co. had published reports stating that the lode, discovered in November 1911 could be traced for 5 miles, that it had an outcrop 30 ft. wide, and that the ore assayed 25% tin. The 300,000 shares rose to £8; they are now quoted at 12s. Only last week it was announced that work on the Jemaa lode had been finally abandoned. I have no space for details, but it is a pitiful story of reckless reports by incompetent men, unwarrantable optimism in London, unpardonable delay in publishing the opinions of reliable engineers, and between each of these factors a manipulation of the share-market that ended in transferring money from the many to the few. Of course, legitimate mining, the real search for tin and the actual washing of the gravel, suffered from this fiasco. It is

a marvel that the public was not frightened to a complete withdrawal. Fortunately, results have been forthcoming. The production of tin in Nigeria has risen from 1470 tons in 1911 to about 2000 tons this year. The inexperienced youngsters and the experienced fakers are giving place to mining engineers able to distinguish cassiterite from tourmaline, and a mine from a hole in the ground. I doubt whether a big industry will ever be developed, but with the rising price of tin, and the comparatively small amount of capital required, it is likely that tin-mining in Nigeria will continue to attract British capital during the coming year. Dredges are being introduced. Systematic ground-sluicing will replace 'calabashing' on some of the alluvial flats. The application of technical skill will increase the area to be exploited, the completion of branch railways will cheapen transport, and the organization of native labor will further reduce operating cost.

NORTHERN AFRICA, SHOWING NIGERIAN TIN FIELDS.

Australasia.—It is pleasant to turn to a brighter aspect of mining. You find that at Broken Hill. While the bonanza orebodies of 20 years ago have been largely exhausted, the Barrier district continues to be not only a big producer of lead and silver, but an important source of zinc. Besides its yield of metals, it has become increasingly the scene of metallurgical advancement. To this important district the rise in the price of lead and zinc, not to mention silver, has been a great help during the past year and promises to be a strong stimulant in 1913. The yield of zinc from the discarded residues of an earlier period has probably reached its maximum, but the extraction of the same metal from low-grade ore and the beneficiation of slime, hitherto intractable, promises to compensate. Broken Hill has had, and is having, a justifiable boom.

Among notable events is the Broken Hill Proprietary's exploitation of the great Iron Knob orebody, where each 100 ft. of deeper mining gives 20,000,000 tons of iron ore. This is situated on Spencer's Gulf and opposite the company's Port Pirie smelter. But the smelting of the iron ore is to be done at Newcastle, where 8 blast-furnaces are being erected. The New South Wales government provides land, wharves, and other facilities. The total expenditure to be incurred forthwith is fully £3,000,000. It is the beginning of large-scale iron-making in Australia. The other neighbors of this celebrated silver-lead mine are also doing well. The British Proprietary began the year with a flourish and the raising of fresh capital for a new equipment. It is estimated that 2,000,000 tons of ore exist between the sixth and tenth levels, but this estimate is not accepted confidently. The ore is low grade, averaging 12% lead, as against the 14% stuff now being broken. Fluctuations in the grade have provoked disquiet, and until the orebody is opened-up further, the real resources of the mine remain questionable. However, they are large, in any event. The North mine has 2,000,000 tons of ore assaying 15% lead, 14% zinc, and 7½ oz. silver. The level now being driven, at 1250 ft., will add about 1,000,000 tons to the reserve, for the ore-shoot is 100 ft. wide and 1000 ft. long, in two bodies. The South mine has about 3,500,000 tons of ore assaying 14% lead, 14% zinc, and 5½ oz. silver. This is found in one shoot including three orebodies, the aggregate length being 1200 ft. with a width of 125 ft., so that each 100 ft. of depth yields about 1,000,000 tons of ore. Both the North and South mines will be increasing their output, but, unless the British develops ahead of expectations, a diminution in the Broken Hill production of lead and zinc may be expected before long. The treatment companies are exhausting the old dumps of tailing. Of these metallurgical companies there are three: the Sulphide Corporation, which controls the Central mine; the Zinc Corporation, which lately acquired the South Blocks; and

the De Bavay company, which gets 45,000 tons of tailing per month from the North, South, and Block 10 mines. The last is now merged with the Minerals Separation, the company owning oil-flotation patents. All of these organizations are doing well. Further metallurgical developments are anticipated, particularly as regards the treatment of slime. This, of course, would add greatly to the efficacy of the processes, and therefore to the tonnage available.

The dominant factor at Broken Hill, next to the revolution in metallurgical methods, has been the gathering of evidence proving the existence of new lenticular orebodies outside the original ore-channel. The first of these was discovered in 1909 in the Central mine, and since then further discoveries off the original lode have been made in the Proprietary, British, South, and Block 10 mines. Of these, the orebody in the British is the most important, but the others also afford favorable indications.

The Australian copper group has become prominent this year, particularly in Queensland. The Hampden-Cloncurry started to produce copper at the rate of 700 tons per month. This is to be increased next year to 800 tons. The company has been aggrandized by the acquisition of the Dutchess, Trekalano, Macgregor, Mascot, and Answer mines. The Mount Elliott has similarly expanded by the acquisition of the Hampden Consols and several prospects. French participation, and gambling, has been prominent. About 120,000 shares out of the 150,000 issued are now held in France. The Herberton district, on the other hand, makes slight progress, so that the Chillagoe, Mungana, and other mines on the limestone-diorite contact are not prominent. The Mount Morgan plant is being reorganized under a new manager. It is also a feature of 1912 that a number of copper companies have suddenly shown a disposition to utilize the oil-flotation methods of concentration. I may mention the Great Fitzroy, Great Cobar, Lloyd, Mt. Lyell, and Mt. Morgan. Charters Towers had a flash in the pan. An effort was made to reopen the McArthur River district in the Northern Territory, but its inaccessibility killed enterprise. On the other hand, several of the older Victorian goldfields such as Bendigo, Ballarat, and Daylesford, have been revived by fresh discoveries of an encouraging character.

Labor troubles have stopped mining operations throughout New Zealand for half the year and hindered them for a longer period. This was notably the case at the Waihi, once one of the greatest gold mines in the world, but now fallen on evil days, for in 1911 the management made a belated confession that the orebodies had 'petered out' on the twelfth level. Sinking of the shaft and further exploratory work were about to be started when the mine was closed, owing to the strike of the miners. The shares quoted at £5½ in 1911 are now at £1⅝. The Talisman, a mine of rare vitality, continues to pay handsomely, but the shares are now largely held in New Zealand. The Consolidated group—Blackwater, Progress, and Wealth of Nations—on the West Coast is doing fairly well, although operations there also have been interrupted by labor troubles.

The big mines at Kalgoorlie are rapidly approaching exhaustion. Shares formerly quoted in pounds are now rated in shillings. The erection of large plants to treat low-grade ore has prevented too rapid a decrease in gold production, but in several cases it has only diminished the ultimate profit. The Great Boulder, the premier mine from the first days of this celebrated goldfield, is still doing fairly well, and is about to obtain a new lease of life by the acquisition of the Great Victoria, a highly promising mine at Southern Cross. The names of the Lake View, Oroya Brownhill, Hannan's Star, and Golden Links are perpetuated by new companies having interests in mines in distant districts, from Nicaragua to Siberia. This prolongation of mining organizations by the acquisition of new properties is an important development of London finance. It has been sanctioned lately by the shareholders in such famous old mines as the Waihi, the Lake View Consols, and the Camp Bird.

Elsewhere in Western Australia not much is doing. The Great Fingall is making a plucky effort to restore itself on the deeper development of a new shoot of low-grade ore. The Sons of Gwalia continues to find supplementary ore-shoots. The young mines, such as those at Yuanmi and Meekatharra, are doing only fairly well. The Bullfinch district, which was the excuse for flagrant booming two years ago, is almost forgotten in London.

America.—As quoted on the share-lists, the American list includes Canadian and Mexican properties. They have not been particularly prominent in London during the past year. The flotation of Boyle's concession and other claims in the Klondyke valley under the name of the Granville Consolidated has drawn attention to dredging in the North, but the interest will be largely technical until such time as results are forthcoming. The three mines at Treadwell, in Alaska, are doing well, especially the Alaska United, which is so placed as to receive the extension of orebodies from the Alaska Treadwell and the Alaska Mexican mines. The recent flotation of the Perseverance, under the name of Alaska Gold Mines, appears to have created some excitement in Boston, but it has attracted small attention here. The same may be said of Porcupine, in which a spasmodic interest was created two years ago. The Northern Ontario Exploration has proved disappointing and is quoted at a sad discount. On the other hand, two or three Cobalt issues have been prominent in London, notably the Casey Cobalt and Cobalt Townsite. The richness of the thin veins and the handsome profits announced periodically have aroused speculation and have prompted the flotation of the Aladdin Cobalt, United States Cobalt, and other companies that start life with names carrying a large responsibility. In Colorado the Tomboy purchase of the Revenue claims is proving satisfactory, and has added another bright page to an honorable record. Across the range, the Camp Bird is now practically exhausted, but its progeny, the Santa Gertrudis, in Mexico, is fulfilling the high hopes of its sponsors, the Grenfell group. This financial house is becoming increasingly influential, for it controls the two mines mentioned, as well as the Messina copper mine in the Transvaal. Another Mexican gold-silver mine is now being examined with a view to purchase with Camp Bird re-

sources, plus participation by the public in an issue to be made during 1913. The old Independence at Cripple Creek is still paying dividends, and promises to end a checkered career with credit to its last manager. The El Oro group is still vigorous, although R. T. Bayliss' report on the parent mine foreshadows its decadence. Deep exploration has proved disappointing. The Mexico continues to be surprisingly overvalued. The Esperanza has been helped by the opening of new stoping-ground on the San Carlos vein above the twelfth level. The Buena Tierra, controlled, like the El Oro Mining & Railway Co., by the Exploration Company, is well considered, although the revolution has hindered its operations, as those of other mines in Chihuahua. The Oroville Dredging is a disappointing venture that expects to mitigate its failure in California by the exploitation of new ground at Pato in Colombia. This dredging scheme has done scant credit to its promoters, and has served to illustrate most of the errors that can be made in a branch of mining now increasing in favor. The Natomas Consolidated, another Californian dredging enterprise, has some of its bonds on this market, and so far has been able to 'make good' on the promises of the prospectus. Californian oil schemes have not been so favorably prominent as had been hoped, but interest in that branch of mining is reviving.

South America has not obtained the attention it deserves as a mineral region, but signs are plentiful that greater activity is pending. Unfortunately, one or two 'lame ducks' cumber the way, such as the Capillitas, Famatina, and Poderosa—all copper mines. The last has done well, but was gutted in the haste to make shipments. However, the Collahuasi district is not finished. Bonds of the Braden copper mine are held in London, and not without a sense of comfort. The successful application of the oil-flotation method of concentration will add largely to the ore available. The South American Copper Syndicate has been able, most profitably, to reopen the old Quebrada mines in Venezuela. Apart from copper mines, the exploitation of gold-bearing gravel has been undertaken by the Aporoma, in Peru, and the Incahuara, in Bolivia, but with inadequate results. Several Bolivian placers are undergoing examination by British engineers, and more may be heard concerning them in 1913, especially if the Oroville Dredging makes a success of its Colombian venture.

India.—The most important event of the year in connection with Indian gold-mining has been the success of operations in the Anantapur goldfield. The grade of the ore treated by the North Anantapur company has increased substantially during the past twelve months, from 5 to 10 dwt. per ton. Recent developments have revealed the presence of a large orebody which at the 450-ft. level is as much as 57 ft. wide in one cross-cut, and averages 25 dwt. per ton throughout its length. The ore reserve has been greatly increased by this discovery and has warranted the erection of another 10 stamps, making the total 30. The Jibutil Mines of Anantapur, another of the John Taylor & Sons group in this district, is also doing well, and is now issuing further capital to complete the equipment. The good results at Anantapur afford a pleasant contrast to the failure at Dharwar. In the older district of Kolar the most important event is the improvement of the ore on the deepest levels of the Champion Reef mine, promising to revive its earlier glories. On the forty-third level in the Carmichael section the lode averages 25 dwt. over 6 ft. The Balaghat, the most northerly of the Kolar group, after a period

of depression, is yielding better results from development. At the Hutti mine, in Hyderabad, the deeper exploration at 2000 ft. has revealed the presence of profitable ore, so that the additional capital recently spent promises to place the undertaking on a sound basis once more. On the whole, this department is not the sport of bulls and bears, but pursues the even tenor of its way, the mines being more under the control of the engineers than is customary among British companies. The total output of gold from the Indian mines is estimated at 584,150 ounces, worth £2,260,000, as compared with 573,525 ounces and $2,150,050 last year.

Russia.—This department has been stimulated by the excellent developments at the Spassky, Kyshtim, and Atbasar groups of copper mines; and it has been enlivened by three new issues, the Sissert, Tanalyk, and Pioneer companies. Some of the derelicts from an earlier boom, such as the Troitzk and Orsk, still survive in the form of priority shares, but they are unimportant, save in a technical sense, for in each case difficult problems are being faced. The Lena Goldfields has declined rapidly, partly owing to bad Siberian management and partly to the exhaustion of the richest gravel. This enter-

prise, from a technical standpoint, is lamentable, for the cost of operations is 25s. per cubic yard and the estimates of the ground in reserve are next to worthless. These defects arise largely from a dual management, the English company being a shareholding company in an enterprise entirely controlled in Russia. The Tanalyk and Sissert are Anglo-Russian concerns. It has been proved that the Russians are eager to participate in these copper ventures; indeed, their eagerness causes the shares occasionally to reach a forced valuation and to place their British-American associates in a difficult position.

THE TRANS-CASPIAN COPPER REGION.

Apparently the Russians have only recently taken to speculation in mining and other industrial adventures. They are new to the game and are readily excited. Likewise our French friends, who have taken large blocks of shares in Spassky, Mount Elliott, Mexico of El Oro, Camp Bird, and other important mining companies. They play too easily into the hands of the crazy optimist and the reckless financier, so that even the sane and methodical controllers of some mines are surprised to find shares being transferred to Paris at a big premium. However, this international aspect of mining speculation, as centring in London, is a feature of growing importance. If recognized fairly and utilized honorably, it should add largely to the scope of our market. Incidentally, it is interesting to record the fact that one or two American financier-engineers have found it profitable to operate on this market, to coöperate with European capitalists, and to inject some of their energy and directness into large-scale mining operations in Siberia, Australia, and the Yukon. This, of course, is pleasing to me, for I regard mining engineering as cosmopolitan and finance as international in their manifold energies.

Miscellaneous.—A Cornish mining revival is explained by the rise in tin. It is of great local importance, but involves no large diversion of capital. The mines in the Malay States, such as the Tronoh, Gopeng, Pahang, and Kinta, have been prominent. A recent Bolivian flotation reminded me that Bolivia is an important source of a most useful metal, but the issue was regarded as 'a pig in a poke' and aroused small interest. In Burma, the Transvaal, and Tasmania the exploitation of tin-bearing alluvium has diversified the share-list, and if tin maintains its present price, as is likely, further issues are to be expected.

No great mineral discovery has been made in 1912; something of the kind is needed to compensate for the decadence of old districts; a great gold-field or a big orebody of the base metals needs to be uncovered, in order to excite the public imagination, not to its disillusionment, but to the appreciation of the fact that modern civilization is based on the intensified use of the metals. It runs on steel wheels, and lives in steel cages, it whispers over a copper or an aluminum wire, it gilds its ornaments and plates its utensils, it is conducted through lead pipes, it is veneered with tin, it paints itself with zinc and lead pigments, and commits suicide with lead bullets or steel shells.

To conclude, the London market remains a dominant factor in world-wide mining. Plenty of capital is available here, as of yore, for new ventures. But the public is less stupid than formerly. The code of financial conduct is higher. The ordinary ineptitude or the common trickery of an earlier decade is today labeled a fiasco or a scandal. Mining is recognized as being risky, as well as profitable. The profit must be proportioned to the risk. The casino of the Stock Exchange is well patronized, but the visitors expect a run for their money: they will pay the stipulated percentage of the tables, but they object to being robbed; they demand a square game. (Comparative quotations for 1911 and 1912 are given elsewhere.)

Electric Smelting.—Some claims have been made of success in smelting zinc ores in the electric furnace. One smelter in Norway has been operating on a small scale, but from the published reports it may safely be said that only such an extraordinarily low current cost as Norway can show made such operation commercially possible. Several experimentors in the United States have published reports of success along this line, and while there is no doubt that success will eventually crown these efforts, none have yet been operated on a scale competitive with the existing retort methods.

The United States Geological Survey and Ore Deposits

By George Otis Smith

While practically every activity of the United States Geological Survey touches the mineral industry, readers of the *Mining and Scientific Press* are most interested in the work on ore deposits.

The various kinds of geologic work overlap at many points but in a broad way the field activities of the metalliferous section may be classified as (1) the investigations of special problems in ore genesis; (2) summary regional reports, especially by states; (3) detailed studies of mining districts; (4) economic reconnaissance; (5) land classification; and (6) special examinations for other bureaus.

In the past the attention of the federal geologists has been concentrated principally on the detailed investigation of important districts and probably few well informed readers will question the scientific and practical value of the results obtained by the monographic treatment of the great mining districts. This work will be continued; for notwithstanding the fact that most of the more productive districts have been carefully studied, new ones are constantly springing into prominence and the continued activity of older ones demands that geologic reports made many years ago should be revised. In spite of these demands, however, the present policy of the survey is to devote more attention than heretofore to some of the other classes of work mentioned, especially to (1) the prompt reconnaissance examination of new districts, so that a general knowledge of the local geology may be made available to the prospectors at an early stage of their work; (2) reports dealing comprehensively with the geology and ore deposits of states or large regional units; and (3) special investigations of problems relating to ore deposition. In the way of investigating special economic problems independently of detailed areal work, the survey has admittedly done comparatively little of recent years. There is now in press, however, a bulletin on the subject of sulphide enrichment by W. H. Emmons and plans are on foot to study more exhaustively certain phases of this subject, particularly the enrichment of silver ores. There are also in active preparation summary reports on the geology and ore deposits of Utah and Idaho. A similar report on Arizona is planned but some additional reconnaissance must be done in that state before all of the material can be assembled.

That the detailed study of mining districts is still an important feature of the work is shown by the fact that the following reports are in various stages of preparation or publication: (1) The Randsburg district, Cal., by F. L. Hess; (2) copper deposits of Shasta county, Cal., by L. C. Graton; (3) the Ely district, Nev., by A. C. Spencer; (4) the Ray and Miami districts, Ariz., by F. L. Ransome; (5) the Tombstone district, Ariz., by F. L. Ransome; (6) the San Francisco and adjacent districts, Utah, by B. S. Butler; (7) the Central City district, Colo., by E. S. Bastin and J. M. Hill; (8) the Creede district, Colo., by W. H. Emmons and E. S. Larsen; (9) the Terlingua district, Texas, by H. D. McCaskey; (10) the Joplin district, Mo., by C. E. Siebenthal; (11) the Ducktown district, Tenn., by W. H. Emmons, F. B. Laney, and A. Keith; (12) the red iron ores of Tennessee, by E. F. Burchard. Besides these there are in preparation a complete revision of the Leadville monograph by S. F. Emmons and J. D. Irving, and of the Tintic, Utah, report by W. Lindgren and G. F. Loughlin. Plans for future work in the general class represented by the reports mentioned are not complete. Mention may be made, however, of the Santa Rita (Chino) and Magdalena districts, New Mexico, and the Jerome district, Arizona. The detailed study of the Homestake mine and vicinity, South Dakota, will be taken up next season by W. Lindgren and S. Paige. Reports in preparation or in press on the Patagonia and Nogales quadrangles, Ariz., by F. C. Schrader; on the Dillon quadrangle, Mont., by A. N. Winchell; on eastern Idaho, by J. B. Umpleby, and on various districts in central Nevada, by J. M. Hill, may be classed as economic reconnaissance. Here may be mentioned also a rather detailed reconnaissance of the Inyo Range, Cal., by A. Knopf and of the Fallon quadrangle, Nev. (including Fairview, Rawhide, and Wonder), by F. C. Schrader. The field work for these has not been completed.

Much of the work directed primarily to land classification yields collateral results that are published as economic reconnaissances, comparable with those just referred to. The principal work of this kind performed during the past season was (1) the examination of the Colville Indian reservation, Wash., by J. T. Pardee, and (2) of the Flathead Indian reservation, Mont., by R. W. Stone.

References to the publications of the survey on metalliferous deposits issued during the past year have intentionally been omitted from this sketch, which is intended to give a general idea of what is being done and, so far as possible at this time, of what is being planned for the future. In so brief a summary, it has been necessary to refrain also from mentioning minor pieces of work, for the most part of reconnaissance character, whose results as a rule appear in the annually issued economic bulletin. The loss which the survey has sustained in the resignation of Mr. Lindgren from the active supervision of geologic work to become the head of the geological department of the Massachusetts Institute of Technology is partly compensated by the gain to the educational world, and fortunately also Mr. Lindgren retains his position as a field geologist in the section of economic geology of metalliferous ores. Mr. Ransome, who succeeds Mr. Lindgren as the chief of this section, is well known throughout the West, having conducted Geological Survey investigations from the Canadian to the Mexican boundary. He will also be in charge of the areal geologic work of the survey west of the 100th meridian, an assignment that will insure the coördination of the general geologic surveys and detailed Western investigations.

Progress in Gold-Silver Ore Treatment During 1912

By Alfred James

Costs

It is singular that for the present year, as in 1906, fine sliming and the treatment of slime have still been the main centres of interest. It is difficult to believe that details of practice determined so long since, and even then capable of producing records not since materially modified, remain of chief interest. Readers of this review may have noticed that since 1906 costs have no longer been a feature in it; this is for the simple reason that they have not yet been notably bettered, at any rate at the mines then referred to. Thus in 1906 rock-breaking was stated to amount to 1.71d. per ton at the Lake View and 1.87d. at the Ivanhoe. At the latter mine the figure for the past year has been 3.93d. Milling at the Ivanhoe was 1s. 9d. per ton; it is now 1s. 8d. Roasting was 2s. 4d. per ton at the Great Boulder; it is now considerably higher. It would be interesting to know if the so-called improved furnaces are really improvements and, if so, why they cannot beat the Great Boulder 1906 record of 2s. 4d. per ton on roasted sulpho-telluride ore. Cyaniding by agitation was then 1s. 4d. per ton at the South Kalgurli, including 7d. per ton for KCN; has this cost for agitation treatment been since bettered locally? Dehne filter-pressing at 1s. 6d. has been undoubtedly cheapened, both in Africa and Australia, to 10d. and 1s., but the Ridgway filter, at that time stated to be giving high recoveries for 4d. per ton, is still preëminent with its total cost of 1d. per ton on a million tons of low-grade pulp and 2d. per ton on high-grade pulp (value say £3 to £4 sterling) not usually treated direct in filters of the submerged vacuum type. It would be as well to again collate costs; old figures become stale, and I shall welcome notes of actual cost per ton handled for crushing, milling, tube-milling, cyanidation of sand, cyanidation of slime, agitating, vacuum-filtration, and filter-pressing. It is a solace to think, however, that in spite of increased costs, the percolation of 1 dwt. sand is still carried on at a profit.

General Tendencies

The reference above to vacuum-filters reminds me of the possible temerity in referring by name to the filter of the best known exponents of the fixed submerged type, but decisions of local courts do not count with the industry to the same extent as the enthusiasm, energy, and skill displayed in forcing this submerged filter on the market. Long ago it was hoped that the pioneer work of G. P. Moore, and the irrespressible enthusiasm and skilled energy of Charles Butters, might result in a combination that would benefit the industry the whole world over, and yet leave room for a liberal reward for the combination. What the courts may or may not decide does not modify the feeling of which that hope was the expression; and if the combination went further and included Askin Nicholas, C. W. Thompson, H. P. Barry, G. Ridgway, and J. V. N. Dorr (surely all pioneers in their way) it would be still more solid.

A feature of the year has been the reported closing down of the last surviving chlorination plants. The expression at the World's Columbian Exposition twenty years since, "Cyanide is king," has surely been amply justified. A practice probably doomed to speedy disappearance is that in Africa of having separate sets of vats for the collecting and possible preliminary leaching of the sand prior to the main treatment. If the new Rand mills, such as the Geduld, be considered, it will be found that reliance is placed on a single set of vats, and this surely is justified by the results of the Princess and East Rand plants. At the latter E. H. Johnson shows some of the highest extractions on the Rand.

Decantation, too, is dead as a process to be adopted at new mills. These are all designed for filtration. Indeed, it is only too evident that Africa is awakening from the benumbing mechanical influence that, up to recently, seemingly confined its metallurgical aspirations to the better preparation of the sand for leaching, and the feeling of satisfaction with local standards is giving way to the keen desire to know more of the successful work of American, Mexican, and Australasian confrères in the solution and recovery of the precious metals, and to adopt such methods locally. Thus the Rand has now in active harness its F. L. Bosqui in addition to its W. A. Caldecott and E. H. Johnson, W. R. Dowling and M. Torrente; Rhodesia, which has ever been on the alert, has brought over A. W. Allen from Mexico in addition to its many celebrated Australian specialists, and even recently sent one of its Australian experts to Cripple Creek to decide some point of advanced practice in which it wished to indulge. This is surely as it should be. The day has gone when men of note can go to New Zealand, Australia, Mexico, and the United States, and come back only to decry what they have seen. Surely the better the expert the greater his capacity for recognizing what is good in outside practice.

Generally, progress for the year has been along developed lines, with no brilliant surprises. Possibly the work of our friend Charles Butters at the Nipissing (to be referred to under 'Amalgamation') is the most daring technical exploit of the year.

Changes on the Rand

On the other hand, owing to the attractiveness of the newer practice of tube-milling to −200-mesh, simple clean classification, air-agitation, slime-filtration, and zinc-dust precipitation, it has been easy to lose sight of steady progress on older lines, such as is evidenced in the design and construction of the mill of the Roodepoort United Main Reef G. M. Co. At a period when new mills on the Rand were under a cloud (relieved later, it is true, by the starting up of the Brakpan and Modder B), the Roodepoort

mill demonstrated how heavy stamps and high duty could be combined with economy in design, in power, and in working costs. Even the huge and carefully planned Randfontein mill, with its cleverly designed scheme for handling ore, must yield in attractiveness to the Albu mill, in which may be noted the soundness of the judgment which has enabled S. H. Farrar, F. Bulkeley, and M. Torrente to avoid extravagances noticeable elsewhere and yet to include just those things (big steel bins, almost vibrationless heavy stamps, tube-mills of large diameter and specially determined length with simple linings, and tailing-wheels) which make it one of the most cheaply operated mills on the Rand. Why should local engineers put in power-eating centrifugal pumps with most costly monthly renewals (£60 per month or more), with uneven delivery of pulp to the spitzkasten, and with an awkward tendency to go wrong with coarsely crushed pulp, when tailing-wheels at less than £10 per month for repairs do all the work with a steady flowing discharge on even the coarsest crushed material?

The Roodepoort mill crushes 20 tons per head per day, and does this readily with only one feeder per battery. This mill is stated to operate for 14 kw-hr. per ton for everything from breaker stations to clean-up and blacksmith-shop, as against the 23 to 30 kw-hr. stated to be usual in African practice. In other words, it crushes and beneficiates 1000 tons of ore per day with about 700 hp., and a peak load under 1000 hp. The mill consists of 100 stamps of 1900 lb., only 50 working. The tube-mills are 6 ft. in diameter and 16 ft. long. Stamping costs 11d. per ton. Milling (complete), including sorting, crushing, stamping, tube-milling, amalgamating, and retorting (everything up to the cyanide plant) costs 1s. 6d. per ton.

The group (Albu) responsible for this mill is also responsible for many of the improvements in Rand practice, including the Denny Bros.' abandonment of long (30-day) percolation of coarse sand particles, the introduction of tube-mills, and of the filtration of slime; and it has thus demonstrated that keenness to investigate and adopt new methods (proved elsewhere) may go hand in hand with economy in first cost and in working expense coupled with large outputs and low power bills. Undoubtedly, up to the present the Roodepoort mill may be regarded as the best example of a modern mill on the Rand of the type general to the field; that is, without air-agitation or slime-filtration.

But, as stated above, this type of mill is now moribund. S. H. Pearce, at the latest Crown Reef mill, takes the precaution of a final air-agitation for his slime prior to filtration in the Butters filter, which has produced so great a change in Rand methods. E. H. Johnson, at the East Rand, was one of the first to approve of filtration and the first to adopt continuous agitation in Pachucas. But the 'Doctor' of the Rand must be F. L. Bosqui; one almost fears to state how low the Bantjes recovery was before he took it in hand, or how great an improvement he has effected in City & Suburban results. African 95% total recoveries have always compared most favorably with those obtained elsewhere. Mr. Bosqui has been evening up the laggards, in one case by recovering increased gold from the slime, and in another case by adopting more modern methods for the treatment of the coarse classified sand.

While writing of Africa, I cannot but wonder at the paucity of practical result of the Mines Trials Committee's work. Local inventors have from time to time declaimed its methods, but the industry may well ask the reason for there having been so little fruit for so much effort; so little result in an industry obviously decadent in solution and recovery methods, until the arrival of fresh blood from America infused fresh energy. The Mines Trials Committee recommends relatively large payments to local promoters of tube-mill cones, nozzles, feed, or lining ideas; but what has it done to encourage foreign inventors to bring in the fresh ideas so much needed in the industry? The Nissen stamp has been forced to a successful issue by an outside group, only by the aid of the unwearying and continuous attention of the inventor, who went to the expense of jeopardizing his other interests by residing on the Rand. But the amount of business up to the present given by the Rand to the inventor will probably not pay his traveling expenses, and if ever the Nissen stamp is adopted by the Rand at its mills yet to be designed, it will be because of the enterprise of Rhodesia in widely adopting it.

Whatever the standpoint of the industry, it may be confidently asserted that any non-publication of results on the ground of communicating useful ideas to non-contributors is a most suicidal policy. Have the contributors really benefited in any single point? The fact is that the secrecy of the committee avoids that effective criticism which alone can lead to the highest and best results. Let the committee either be disbanded or reorganized, with power to immediately publish the results of its investigations.

Other Countries

From Africa to India is a far cry. Some delay has taken place in the introduction of the newer methods (tube-milling and slime-filtration) referred to last year, but come they surely will. From New Zealand comes the story of a tailing plant, perhaps the largest in the world, ably described by C. A. Banks,[1] who incidentally explains how the injurious carbonaceous content is cleared off by vanners. If only those undertaking similar work would be guided by the successful results so frankly described, much avoidable loss would be saved. Thus a similar project in South America has twice invited and experienced failure through relying on pumps for dredging of the submerged tailing. A. W. Allen's article[2] shows how the greatest success has been achieved by using an air-lift in place of the pumps. The antimonial problem at the Gwalia Consolidated, in Australia, does not yet appear to have been solved, although it has been before many of the leading metallurgists of the day. The latest idea is apparently to work on lines similar to A. Richards' tin volatilization process.

From Mexico there is but little to chronicle this

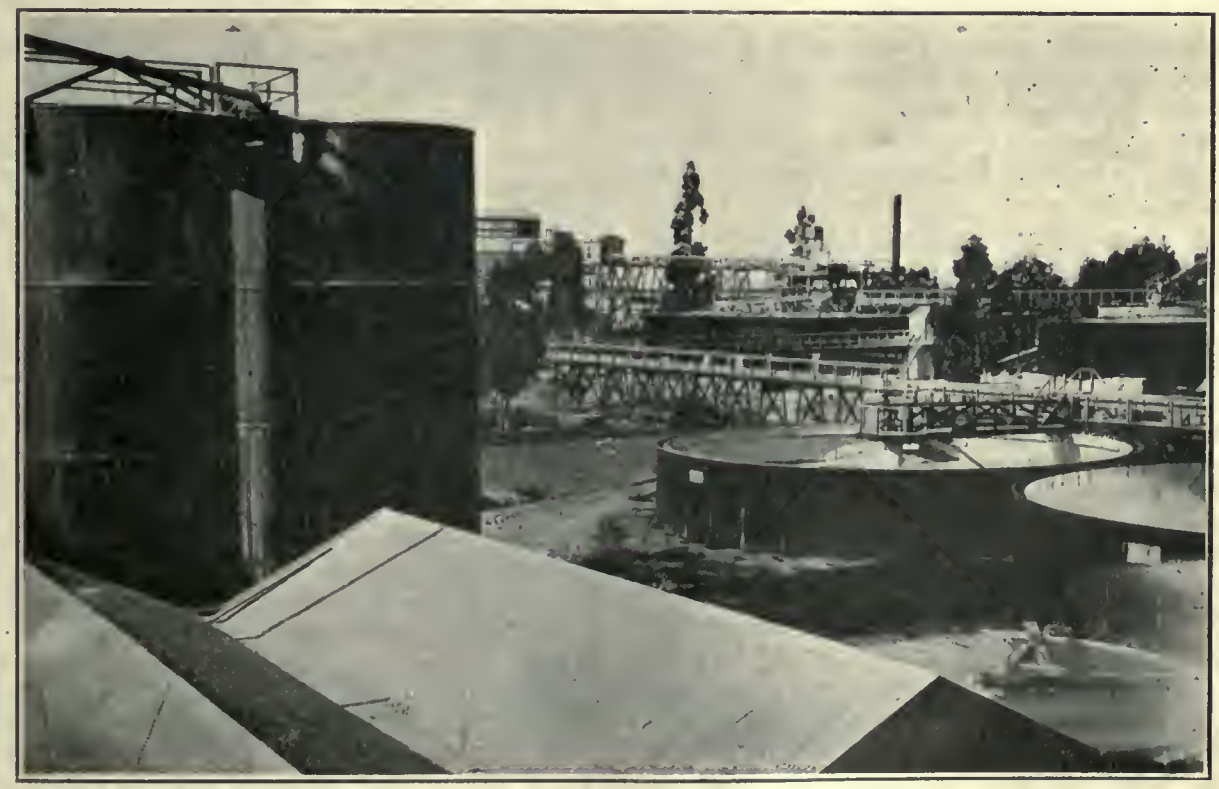
ROODEPOORT UNITED MAIN REEF G. M. CO. MILL.



MODDER B CYANIDE PLANT.

year. The disturbed internal condition of the country is naturally responsible for a setback, but the Santa Gertrudis has signalized the first year with its new plant by paying a good dividend. It has also increased the capacity of its mill to 850 tons per day, which is a good criterion of the success of its methods, referred to in detail in the review of last year. From the United States there is word of new mills containing much of interest, even though there may be no departure from the methods described last year. The Colburn mill, which was watched with especial interest, has apparently had a setback. Good news is at hand of A. L. Blomfield's work at the Golden Cycle mill; it is hoped soon that the technical press may contain an account of the interesting sand-feeder used in the cyanide vats. Phillip Argall has been continuing his very successful work at Stratton's Independence,

beneficiating refractory low-grade telluride ore at the remarkably low cost of $1.50 per ton. A. J. Clark and W. J. Sharwood's description of the metallurgy of the Homestake[3] is a valuable contribution. Attention is specially invited to the notes by Whitman Symmes[4] on the Mexican mill, Virginia City. The criticism of equipment and methods of a mill employing such up-to-date apparatus as Trent agitators and Oliver filters and zinc-dust precipitation is valuable and corroborative of impressions gained elsewhere. At Tonopah important improvements have been made and the Tonopah-Belmont mill is widely praised, though no detailed account of its work has been published.

Details of Practice

New Mills.—As stated above, there have not been many new mills designed this year; perhaps Rhodesia has been the most active centre. There the Shamva mill uses 56 Nissen stamps, 9 tube-mills, and the Butters filter (336 leaves). The Falcon uses 36 Nissen stamps. The Cam & Motor includes roasting furnaces, Argall driers, and vacuum-filters. The Antelope also has Edwards furnaces and Dehne presses, with ball-mills and pans. The Bell has roasting furnaces, ball-mills, tube-mills, and Dehne presses. The tendency is wellnigh universal for new mills on the Rand to have 1900-lb. stamps, 10% tube-mills of size settled by M. Torrente (that is, wider and shorter than the Rand mines pattern), Brown agitators, and Butters filters. The practice is gaining ground of direct fall from stamps to tube-mills, thus obviating the present custom of elevating the very coarsely crushed pulp so destructive to pump linings. The new Van Ryn Deep mill is to have the usual gravitation stamps and the Butters filter. In Mexico, the Pozos and the Angustias have Pachuca vats and probably vacuum-filters (Moore type); Paterson agitators and Oliver filters are being also adopted. The Palmarejo new mill has been delayed by the revolution, but as no description of this has yet appeared, and as certain features are still novel (notably the sectionalization of stamps so heavy as 1250 lb. for mule-back transport), some reference seems not out of place. Limited by the water-power available (only 600 hp.) and by the difficulty of transport, advantage was ultimately taken of the most approved methods. The employment of such heavy stamps was found possible without the necessity for light cam-shafts by limiting the length of the latter and having three stamps only to a mortar-box. Samples are automatically taken between the feeders and the mortar-boxes and conveyed by belt to the sampling-floor. As originally designed, concentration took place both before and after the tube-mills, but it was found possible to do away with the coarse sand tables and to rely entirely on the slimers. Dorr classifiers were originally specified for the tube-mill feed, but were ultimately displaced by Bell cones with sight regulation. The percentage of tube-mills (16 ft. by 4 ft. 4 in.) to stamps is 16.6. The tube-mills are sectionalized by the system of longitudinal channels originally tried with so much satisfaction at Redjang Lebong, in Sumatra. Neal's discharge is provided. A conveyor keeps the tube-mill floor supplied with pebbles or ore. After concentration the thickened slime pulp flows to six standard Pachucas, followed by two storage decanters. Filtration is by Merrill press, with clarifiers for decanted and other solutions. Precipitation is by Merrill press in two circuits with provision for a final flow through zinc shaving, as at El Rayo. Precipitate is melted in revolving tilting furnaces of the Kalgoorlie type. In Australia the new mills, the Bullfinch, the Corinthian North, and the Ora Banda, are all on filtration (Ridgway) lines.

Agitation.—S. D. McMiken has shown[5] how at the Komata Reefs he is able to run ten Pachucas, 38 by 10 ft., with 8 hp. Modifications in internal air-lift pipe lengths failed to improve the extraction. In South Africa the Pachuca has been adopted at some of the best known mines, notably the Robinson, Crown, Brakpan, Modder B, and East Rand. Demonstration runs have also been made by the Trent and Hendryx agitators. The published results of the latter show high recoveries in a very short time, with a very low consumption of cyanide. It is to be wished that W. E. Hendryx had carried his demonstrations further, so as to show precisely what advantage the industry would obtain were it to agitate the total product in an agitator in place of percolating the sand as at present.

Generally, experience in gold-ore treatment, as contrasted with silver-ore treatment, indicates that the fine grinding of sand and the agitation of the finely ground product do not yield enough higher results over ordinary percolation to justify the extra cost of equipment and treatment as slime product. Therefore the gold mines find it pays best to still separate the sand and percolate it. Mr. Hendryx' results show a residue of 0.05 dwt. from agitated slime as against a residue of 0.281, 0.35, 0.25, and 0.55 dwt. for sand and slime mixed. If it be assumed that half the mixed residues are slime at 0.05 only, it brings the sand residue to a very high figure.

The collapse of the Way-Arbuckle agitating plant has been so fully referred to[6] as to need no further comment, except as to the extraordinary condition of affairs which could permit the occurrence of a foreseen and foretold disaster of such magnitude; the loss has been reported to have been as much as £200,000. A contribution to the technology of the subject is that of J. E. Alley.[7] He shows how packed concentrate, settled into a cement-like mass, may be easily started up in a Pachuca by a method even simpler than that at the Alaska Treadwell referred to last year. In filter plants of the Butters type, where considerable storage room for pulp has to be provided, the provision of an efficient agitator in large mills has long been a pressing problem. The Australian type of agitator seldom exceeds 25 ft. diam. Hoyle's Esperanza classifier, a most likely type, could be 40 ft., or even 50 ft., but at the Modder B there is at the Butters plant a pulp stock-tank 60 ft. in diameter with smooth-running.

under-driven, effective agitation, taking from 8 to 12 hp. at 4 r.p.m. This agitator (Central Mining & Investment type) is undoubtedly the best for the purpose which has yet come under my notice.

Amalgamation.—Since the Waihi G. M. Co. adopted amalgamation on plates set in a row away from the battery, this practice has progressed far and wide. In Africa the area of plates has been cut down by as much as 75%. Amalgamation now takes place only after tube-milling: the wear and tear of the coarsely crushed pulp on the after battery-plates is thus avoided. H. Stadler, who from time to time interjects some able criticisms on local practice, is not satisfied with the efficiency of the abbreviated plate area, but the Caldecott group is keen on the advantages they claim to thus derive. Undoubtedly the most daring practice is that introduced by Charles Butters at Nipissing.[8] No less than 40 tons of mercury is in circulation and the ore, containing native silver, argentite, and arsenides of cobalt and nickel, is ground in a tube-mill with mercury in greater weight than that of the ore charge and with 5% KCN solution. Air is introduced and a 98% extraction is reported in 9 hr. The silver in solution is precipitated by zinc shaving, and the mercury amalgam collected, retorted, and melted, with a resultant product of 999 fine. "It is well known that grinding in an iron mortar or pan with an excessive quantity of mercury will usually result in total extractions with even the most refractory ores,"[9] and it was this fact that induced the Cassel company, in the early days of cyanide, to standardize the two amalgamation tests ('ordinary'=plate amalgamation, and 'forced'=pan amalgamation) given on the page above quoted, as it was found that with other proportions the tests were liable to give results not comparable with those actually obtained in practice. In applying this procedure to general practice, I should have anticipated a large accumulation of sickened mercury. But sickened mercury may be retorted or even purified by other means, and it is to be hoped that ere long Mr. Butters will publish some description of the results of his undoubtedly bold, even if not ultimately successful, venture. Clark and Sharwood, in their valuable paper, already cited, refer to the exceedingly slight penetration into the plate of the amalgam coating, and this is confirmed by McMiken, and Halse.[10] On the other hand, comment has been heard frequently on large amounts absorbed by plates, and as to plates being practically eaten through by amalgam. It would appear that unless plates are specially soft, the gold accumulation scarcely penetrates below the skin of the plate, even though the latter may be eaten through with mercury.

Classification.—W. A. Caldecott's cone and table, worked together, make probably one of the best products for cyaniding ever fed into a vat. In Africa, until recently, full advantage has not been taken of this fact, and even at the Simmer the product is fed with cyanide solution into collecting-vats and transferred into leaching-vats. It is obvious that with such product collecting-vats are an unnecessary expense (they already existed at the Simmer), and H. A. White, at the Princess, has shown how good are the results obtainable by direct treatment of the product. But cones are troublesome; they require continuous attention, and thus even the Caldecott table does not excite an enthusiasm for cones in comparison with the automatic simplicity and perfection of the continuous work of the Dorr classifier. But a further advantage of the Caldecott table is the dryness of the product—under 15% moisture—which enables the balance of solutions (15 to 20%) to be maintained with something in hand. Classifiers of the Dorr and Hoyle types just exceed the point, say 20 to 25%, and make draining the vats or some intermediate step necessary. Argall claims with his Ovoca classifier, working so successfully at Stratton's Independence, to give a drier product as a result of the compression of the pulp between his two spirals and to come just within the point, say 18 to 20%, and this type has accordingly been adopted in the most recent design of a large mill for Queensland.

Crushing.—The good results of the Nissen stamp have been confirmed in practice. New mines on the Rand, with their heavy stamps and open-front mortar boxes, show, with the notable exception of the Roodepoort United Main Reef mentioned above, an extraordinary vibration of cam-shafts, and in at least one case, of stems. The smooth running of the Nissen stamp at the City Deep has caused much favorable comment, and has undoubtedly been a factor in its adoption in the new Rhodesian mills. The tendency is to employ wider mesh screening. At the Modder B, one of the latest mills, it is found that, with eighty 1600-lb. stamps, 8-mesh screening gives 11 tons per head per diem, and 3-mesh 16 tons. A useful table of variations in output for different mesh screens is given in 'Rand Metallurgical Practice,' Vol. I, p. 75. The most recent mill to start on the Rand is the Consolidated Langlaagte, with its 100 stamps of 1900 lb. each. It is probably the first mill in South Africa designed to produce more slime (60%) than sand (40%), and is thus a notable indication of the trend of local practice now that more efficient slime treatment (by filtration) is admitted to be available.

Tube-Milling.—Recent mills in Africa have the tube-mills set diagonally to the centre-line of the mill, to economize space and to afford a more convenient belt drive. The expensive Citroen gear of the City Deep type, with its direct drive, has not been generally adopted. Belt drives appear to be preferred for the majority of the new mills. Ribbed liners of the Osborne type, and liners made up of concrete blocks studded with steel projections (old drill ends) are displacing silex. They are stated to have the advantage of longer life and of collecting amalgam scoured off the plates. Indeed, the relining of a tube-mill is now found to add as much as 400 or 500 oz. to the output by the recovery of the amalgam collected by the old liner.

Authoritative tests will still be required on the loss in efficiency caused by the employment of ore in place of selected pebbles, and the money loss or

[8] *The Mining Magazine*, June 1912, p. 452.
[9] James, Alfred, 'Cyanide Practice,' p. 33.
[10] *Trans.* Inst. Min. & Met., Vol. XVII, p. 486.

gain resulting from such loss of efficiency as against the crushing in place of pebbles of some, it may be, 8000 or 10,000 tons of ore per year.

Filtration announcements have been less assertive than usual. Merrill, Kelly, Sweetland, and Burt have not been so much discussed; the Moore and Butters filters about maintain their positions, with the Oliver coming into wider use in spite of the condemnation of its washing capacity expressed in Whitman Symmes' article, already cited. In Africa the good results of the Butters filter have undoubtedly caused excitement, even though they are not accepted as convincing by some engineers who are possibly at a loss to give valid reasons for their non-conversion. Expense of equipment is one of the excuses put forward: smallness of margin of recovery over decantation is another. An article in the *South African Mining Journal* of January 6, 1912, might therefore be referred to. At the Bantjes the extra cost was given as 3.4d. per ton treated, the extra extraction as 0.6 dwt., or say 2s. 6d., showing a gain of over 2s. per ton. This is, of course, an exceptional instance. At the New Modder, out of a total cost for slime treatment of 13¼d., the separate cost of the Butters is 4d. per ton, the total gain in extraction 11%, or say 8d., less 4d., equaling a gain of 4d. At the Crown Mines, for an extra cost of 3.6d. there was an extra extraction of 0.2 dwt., or 10d. From Australia come accounts of the Ridgway reciprocating unit. It has apparently been adopted by all the latest plants irrespective of groups, and by such well known, but differently controlled, companies as the Great Boulder, Associated Northern Blocks, and Sons of Gwalia. It claims a wide range of material from roasted sand to Bullfinch kaolin ore. It has been found there that the fixed submerged filters, when run on high-grade ore, tend to an extraordinarily great accumulation of gold in the wash water.

Heating Solutions.—W. A. Caldecott and W. R. Dowling heat solutions to 90 to 120° with waste steam at Knights Deep slime plant, circulating them through two 6-in. centrifugal pumps at a cost of 25 hp. for 2000 tons per day. They claim good and clear settlement of solutions in the slime-plant, with a consequent increased (20%) tonnage treated.[11] A. H. Jones[12] shows the improved results obtained by him with solutions heated to 90 degrees.

Precipitation.—Reference is again made to Whitman Symmes' paper, cited above, for a note of his difficulties when using zinc dust and his method of overcoming them. The Merrill zinc-dust method has not bulked so largely in the technical press of late. F. A. Vestal[13] gives his experiences at the Empire mines. Doubtless further progress will ere long be reported, although reversion to zinc shaving is reported by the Esperanza Mining Co., which after long use of the zinc-dust method now passes its gold-bearing solutions, after they come from the Merrill zinc-press, through zinc shaving. It will be remembered that this is H. Colbath's practice at El Rayo, described in this review for 1910. A. J. Wyly refers to his precipitation at Simau with zinc shaving. One box containing 1200 lb. of zinc shaving precipitates daily 140 tons of solution containing 0.04 to 0.4% KCN, 0.6 to 20 dwt. gold, 1 to 10 dwt. Ag, so perfectly that the outflow assays 'traces' only.

Roasting.—It will have been noted that some of the latest Rhodesian plants are built on Kalgoorlie roasting lines. The long hearth Edwards duplex furnace has been adopted for antimonial ores. This may be a grave mistake. The volatilized antimony tends to condense on the cold ore at the far end and thus to accumulate until the furnace is put out of action. It would appear better practice to choose a furnace in which provision is made for taking off the volatilized antimony before it comes in contact with the fresh charge.

General

During the year an attempt has been made in the *Johannesburg Star*, and later in the special anniversary number of the *South African Mining Journal*, to raise a fund for the benefit of those pioneers who, having spent the best part of their lives in introducing and taking charge of the working of the cyanide process on the Rand, now find themselves, after over twenty years' service, without that provision for their old age which they might have anticipated had the industry not succeeded in upsetting the MacArthur-Forrest patents and thus terminated the interest of the company which alone would have been able to grant pensions to the pioneers. It is not much to ask that in return for the free use of the cyanide process, and the special equipment, such as zinc boxes, designed for this purpose, a small sum per box used should be set aside as the nucleus of such a fund. It is stated that, not long since, an employee bearing an honored name in metallurgy, after some twenty years' service in perhaps the richest and most famous mine, was found dead the day after he had received notice to quit. It is hoped this fund will prevent the recurrence of such an incident, which redounds neither to the honor nor the gratitude of the Witwatersrand gold industry.

Portuguese Dredges

The Union Construction Co. has designed a tin-dredge for Portugal, which is being built by Fraser & Chalmers of London. The dredge is to be equipped with 5-ft. buckets, and will be built on lines somewhat similar to the tin-dredge which has proved so successful on the Seward Peninsula. An item of interest to dredge construction companies is the news that the Union Construction Co. has entered into an arrangement to act as consulting engineers for Fraser & Chalmers, Ltd., in the building of dredges for gold and tin, and it may be expected that a number of decided changes and improvements will be made in foreign construction

The Bucyrus Co. is building a 7½-ft. dredge with steel hull for the Andrada Mines, Ltd., of Portuguese East Africa. It will be shipped to Beira early in 1913. It is understood that there is a barren clay overburden of from 2 to 15 ft. and the gravel is 5 to 20 ft. deep. It may be decided to first hydraulic the overburden.

[11] 'Rand Metallurgical Practice,' Vol. I, p. 223.

Concentration by Flotation

By Edward Walker

Experience gained during the past year has tended to prove the superiority of the flotation process operated by the Minerals Separation, Ltd. as compared with the Elmore and the De Bavay processes. I cannot say anything of the Potter-Delprat process, because this is worked solely by the Broken Hill Proprietary, and the results are never published. The simplicity of the Minerals Separation plant and its consequent cheapness is one of the points in its favor, and the second is that the presence of slime does not interfere with its efficiency. As regards the first point, it has a great advantage over the De Bavay process, the plant used in connection with which is costly. The Minerals Separation company has found that the rapid churning of the pulp in contact with oily substances has been of the greatest importance in improving the practice. This action has the effect of thoroughly incorporating air-bubbles and oil, and so making a permanent froth which holds the sulphide particles tightly. In this connection I may remind your readers that the pathway among rival patents in connection with flotation processes is full of snares, and that a passage along it requires exceedingly skillful steering. In this particular case the adoption of the apparatus for rapid agitation brings Minerals Separation in possible conflict with J. D. Wolf, who in his English patent 4793 of 1903 and United States patent 787,814 describes an apparatus of this kind. It is true that Mr. Wolf was the loser in an action at law some years ago, but the point on which that lawsuit turned was in connection with a different phase of the flotation principle.

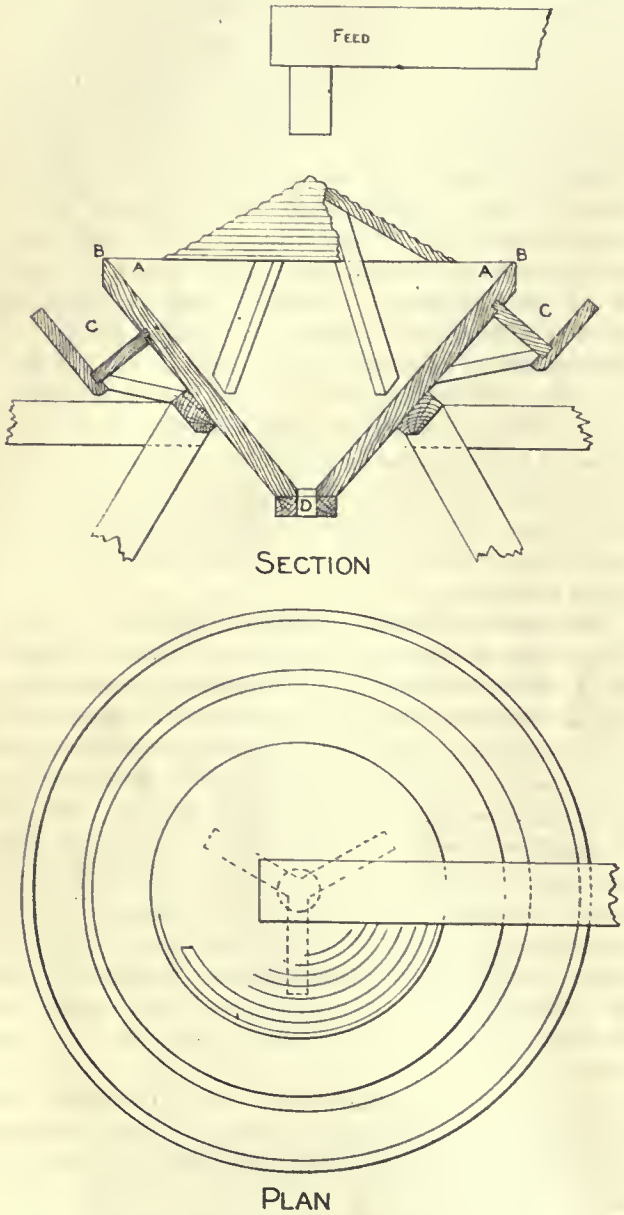
Several references have been made during the past year in various periodicals to the action taken in the United States by Minerals Separation against James M. Hyde for infringement of their patents, consequent on his erection at the Butte & Superior mine in Montana of a plant that bears close similarity to that of Minerals Separation. In fact, his patent differs only in trifling details from those of the Minerals Separation covering this particular type of machine. A large amount of evidence has been taken on commission in London in connection with this lawsuit. Mr. Hyde's general line of defence is that the Minerals Separation process does not disclose any previously unknown principle or mechanical method of carrying such principle into effect. The Everson patent of 1885 is held to have disclosed the combination flotation effect of oil, acid, and bubbles, and the Wolf patent is taken as covering the rapid agitation method. As a matter of fact, the discovery made by Minerals Separation was the efficacy of minute amounts of oil or analogous substances when used to produce a froth by means of rapid agitation. The virtue of the smallness of the amount of oil was discovered by Sulman & Picard.

The dispute between Minerals Separation and the De Bavay company has been settled during the year without recourse to the courts of law. It has been generally held by people acquainted with the facts that the De Bavay process infringed every other flotation patent ever granted. The owners of the De Bavay patents in Australia, where the process was developed, strengthened their position by acquiring the rights of the Potter hot-acid process. As the Minerals Separation process uses a hot solution containing acid, it was presumably reckoned an infringement of the Potter process. This fact must have formed the basis of settlement, and have acted in the negotiations as a powerful offset against the alleged infringement on the part of the De Bavay. Otherwise the controllers of the latter would never have secured 45% interest in the royalties earned by the Minerals Separation in Australia. Moreover, there is little likelihood of the De Bavay process being applied anywhere else than at the North, South, and Block 10 mines at Broken Hill, as it is obviously of inferior efficiency to that of the Minerals Separation company.

Reference to patent litigation would not be complete without mention of the fact that the appeal to the Judicial Committee of the Privy Council from the Australian judgment relating to the dispute between Elmores and Minerals Separation has not yet been heard. In this Australian lawsuit, Elmores sued the Sulphide Corporation, alleging that the Minerals Separation process infringed their patents of 1898 and 1901 for the use of oil and for the addition of acid to increase the attraction of oil to the mineral particles. The court held that there was no infringement, and it is from this judgment that the Elmores are appealing. It is obvious that until this case is finally settled, the use of oil cannot be said to be freed.

The De Bavay company has never permitted the publication of details with regard to their process, and the first appearance of anything approaching a true description is to be found in Theodore J. Hoover's book on 'Concentrating Ores by Flotation.' The disinclination of the company is due to long-standing disputes as to the ownership in the several countries of the patents governing the use of oil, aeration by agitation, acid, and surface tension, and also presumably to the fact that it was impolitic to let outsiders know the exact procedure. The earlier De Bavay patents pointed to the application solely of the principle of surface tension without the use of oil, acid, or aeration, but since then the value of oil and aeration has been recognized. But the surface-tension idea was not new, as it was described by Bradford in 1885. In the De Bavay process as now applied, the zinc tailing is first de-slimed, then agitated with a cold acid solution to remove oxidation products and so thoroughly clean the sulphide surfaces. Subsequently it is washed to remove all trace of acid. After this washing is complete, a small amount of scum of sulphide particles remains on the surface of the water; this is drawn off and sent to vanners for recovery of lead sulphide. The tailing

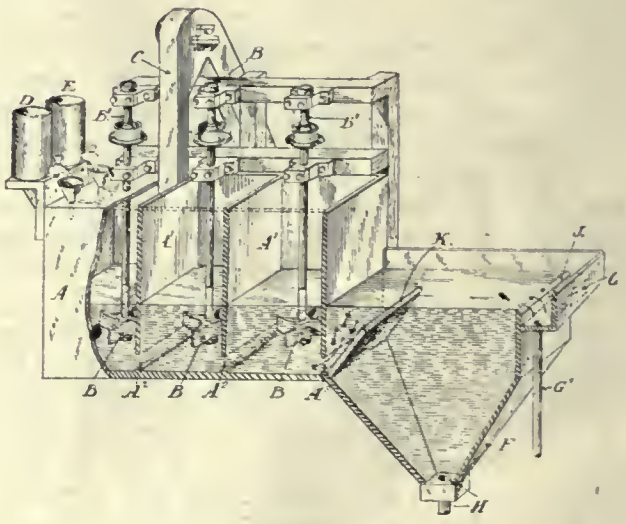
that settles is transferred to an oiling vat, where it is again agitated with water to which a definite proportion of oil has been added. The oil is a mixture of 1 part of castor oil to 4 parts of low-grade kerosene; 2 to 3 lb. of this is used to 1 ton of tailing. Some chlorine gas is also introduced. The oiled pulp



DE BAVAY FLOTATION APPARATUS.

is elevated in a montejus by means of compressed air to the first tier of separating cones. One of these cones is shown in the accompanying illustration. The pulp is fed to the top of the cone and flows down over a series of corrugations to the water-level *A*, where some of the sulphides float and pass over the lip *B* into the launder *C*. The remainder falls to the bottom of the box, passing through the orifice *D* to a second cone, where a further amount of the sulphides float on the surface of the water. The tailing goes subsequently to third and fourth cones, where the process is repeated. The function of the chlorine gas is obscure. The subjecting of the pulp to compressed air is apparently an essential part of the operation. If so, the process is analogous to other oil-and-aeration processes. Mr. Hoover draws attention to the high initial cost of the plant. The capacity of each cone-unit is low, and the plant is both large and high, and covers much ground. The new plant of the Amalgamated Zinc company at Broken Hill to treat 1800 tons per day cost no less than £200,000.

At the November meeting of the Institution of Mining and Metallurgy, H. Livingstone Sulman gave a practical demonstration of the 'agitation-froth' process, as the Minerals Separation has officially christened the method. He exhibited the small testing plant, and showed how the agitation of the oiled pulp by means of rapidly revolving beaters churned air into it and caused a mineral froth to rise to the surface. I take this opportunity of illustrating the method as adopted in the treatment-plant, and I cannot do better than reproduce the drawing that appears in Mr. Hoover's book. This diagram is the most convenient for explaining the process, though many improvements in construction and detail have been introduced. The apparatus consists essentially of three mixing and agitating compartments *A*, the last communicating with a modified spitzkasten *F*. The interiors of the three compartments are connected together by apertures A^2 in the bottom of the partitions A^1. Oil is fed through *E*, acid through *D*, and the ore-pulp through *C*. The agitators *B* are driven rapidly so as to create the froth, which when the pulp emerges over the baffle-plate *K* in the spitzkasten floats and passes over the lip *J* into a launder. The pulp is kept at a temperature of 70° C. Full de-



MINERALS SEPARATION APPARATUS.

tails of the plant and the results are given in Mr. Hoover's book,* to which I refer your readers, with the remark that this book is the most important published in connection with metallurgy since the early books on the cyanide process.

Of the other flotation processes, that of the Murex is the only one to attract attention. This is not strictly a flotation process, for the removal of the sulphides is effected by magnets after some magnetic substance such as magnetite has been added as an emulsion to the pulp. The process has given satisfactory results at the Cordoba copper mine in Spain, where the large proportion of calcite had vitiated any process involving the use of acid. A large plant is being erected at the Whim Well copper mine in the northern part of Western Australia.

Zinc Production and Smelting in 1912

By R. G. Hall

The year has been an especially prosperous one for the miners of zinc ore—and not been without its compensations for the smelter men. It opened with a recession from the high price of spelter of the latter half of 1911. At no time, however, did the price fall below 6c. per pound, and it continued to increase with occasional recessions, until the latter half of the year brought record prices of close to 7½c. at St. Louis. While at this writing it is impossible to more than approximate the total production of spelter for 1912, it can safely be said that it will be of record-breaking tonnage and be probably not far from 340,000 tons from domestic ores alone.

Ore Production

The production of ore has kept pace with the increasing demand and the price for spelter, so that the older districts are today operating and producing ores at a rate in many cases unsurpassed in their history. It has, however, been much of a disappointment that the increasing prices for metal and ore have not led to discovery of any new districts of importance in the Rocky Mountain country.

Joplin District.—The output of the Joplin district for 1912 will be approximately.

	Tons.
Blende	295,000
Calamine	19,000
Total	314,000

The production will be probably somewhat above any year's production hitherto, and the price paid also establish a new high record, at least for the last half of the year. The shipments by weeks, all grades, as given by Zook's Car Report, and prices of spelter, St. Louis and London, are given opposite.

Wisconsin District.—The production of the Wisconsin district for 1912 will be approximately 100,000 tons, showing some increase in production for this field also. The prices paid follow closely those in the Joplin district.

Montana.—The production of Montana for 1912 was almost entirely from one mine, the Butte & Superior. The total for this property during the year will approximate closely 30,000 tons of concentrate averaging 46 to 49% zinc content. Early in June the Butte & Superior company gave up the use of the concentrator at Basin and started the first half of its new mill with a nominal capacity of 500 tons daily. This mill is equipped with jigs and tables followed by the Hyde flotation process on the tailing. The latter process is said to have been discarded and the mill is now being rearranged.

Colorado.—The production of Colorado made an immense increase for the year; practically all of it from the carbonate deposits of the Leadville district. No reliable statistics are at hand, but it is

Nevada.—Practically all the zinc ores shipped from Leadville will approximate 175,000 tons of all grades. For a long time the smelting companies refused to accept carbonate ores much below 30% zinc, but during the last half of the year a considerable tonnage of 22% was contracted for and some was said to have been sold down to 18%. The total tonnage of zinc sulphide ores in Colorado probably changed but little from 1911. The Empire Zinc Co. increased the size of its mill at Canon City. The ore supply for this mill comes for the most part from its own Col. Sellers mine at Leadville. The United States Zinc Co. at Pueblo, and a mill in Denver are the only others operating on Leadville zinc ores. The Wellington at Breckenridge and the Eagle at Red Cliff continue to be considerable producers of zinc concentrates. Crude ore and concentrate are produced by various other concerns, but the tonnage is small.

JOPLIN PRODUCTION AND ZINC PRICES

Week.		Tonnage produced.	Average base price.	St. Louis spelter price.	London spelter price.

Arizona.—The zinc produced by Arizona in 1912 came for the most part from the one property, the Golconda, and allied properties in Mojave county.

New Mexico.—The zinc shipped from New Mexico come mostly from the Magdalena district. The Tri-Bullion property continued the principal producer, with about 7500 tons of concentrate. The mill built by the Ozark company for dry concentration proved unsatisfactory, and that is now being replaced by another process. Zinc ore continues to be produced from other parts of the state, notably the Silver City and Pinos Altos district, and while the total is small, progress has been made.

Nevada.—Practically all the zinc ores shipped from Nevada were carbonates from the Good Springs dis-

trict. These ores occur in many cases associated with lead carbonate, but a successful separation has been worked out so both metals can be recovered.

Idaho.—The Coeur d'Alene district, as usual, supplied the bulk of the zinc produced in Idaho in 1912, the Success mine being the leading producer. The Morning mill continues to use flotation and the McQuisten tubes for recovering the zinc from the lead-mill tailing, and the mill has been enlarged. This and other properties increased their output some in 1912.

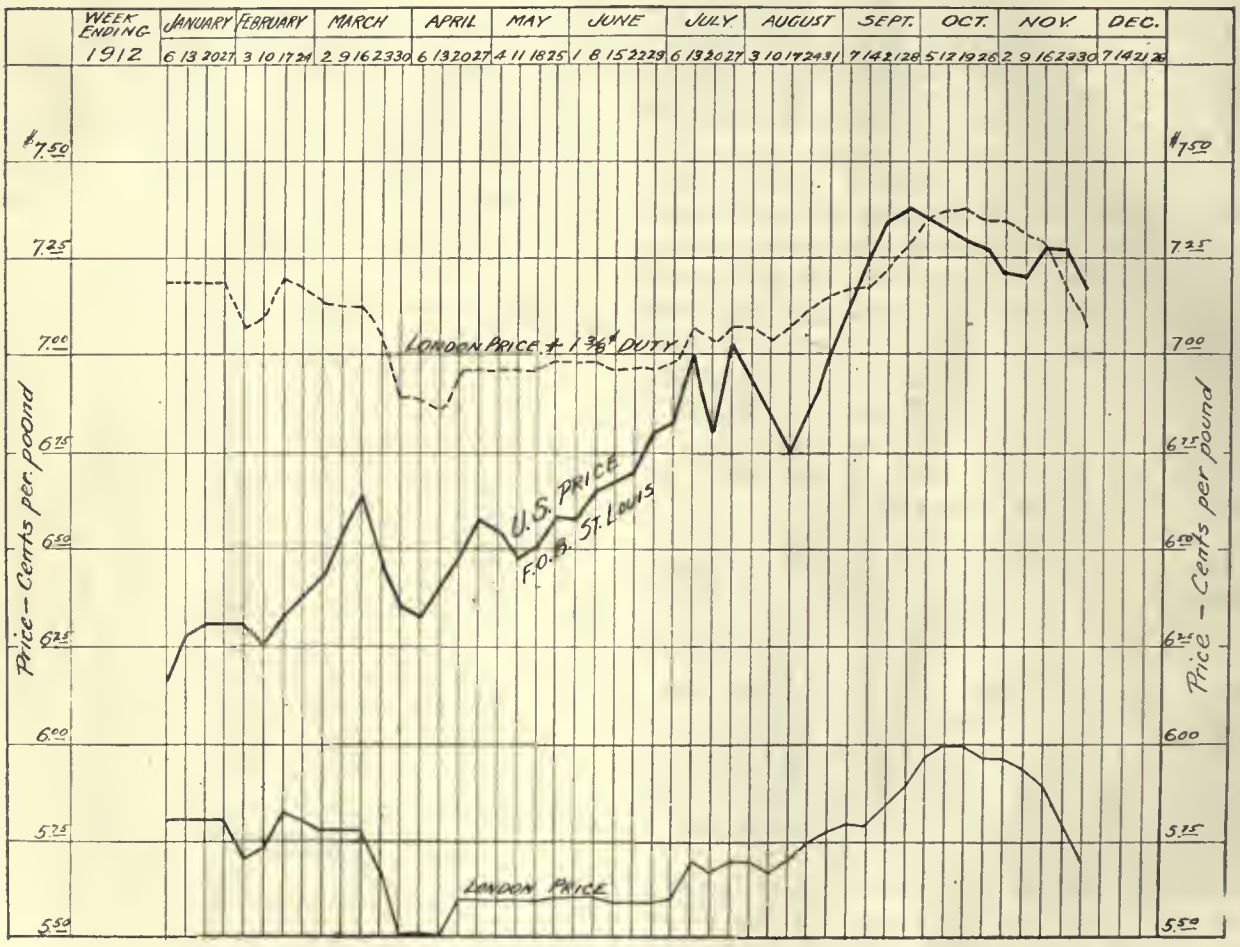
California.—One mine at Keeler shipping carbonates, continued to be the only producer of note this year. There is a mill at Needles producing a small tonnage of concentrate from ores mined mostly in Arizona.

Tennessee.—That zinc occurs in considerable quantity in eastern Tennessee and southwestern Virginia has long been known, and in the early '90s a considerable tonnage was mined and shipped. The crude ore is low in grade and difficult to treat because the blende is finally disseminated through the rock, but the recent rise in prices has attracted renewed attention to the district and large scale production is predicted. Among the concerns especially interested may be mentioned the American Smelting & Refining Co., and the American Zinc & Lead.

Mexico and British Columbia.—Most of the ores shipped to the United States for smelting are smelted in bond and the metal exported again. The disturbed condition of Mexico has prevented many properties from operating, and the actual import of zinc ores from there has been relatively small in 1912. Imports from Canada have not been large in recent years and show but little increase this year.

Zinc Smelting

New Construction.—No new developments have taken place in the methods of smelting during the year. Additions or new works have been built in the Oklahoma gas field. The Tulsa Fuel & Mfg. Co. has completed or nearly completed seven furnace blocks in Collinsville, and the Bartlesville Zinc Co. has completed, or has under construction, at the same point 12 blocks. Against that there has been a decrease of available capacity, notably in the Kansas field owing to shortage of natural gas. The supply of gas in both states available for smelting purposes is being rapidly curtailed, partly owing to the exhaustion of old fields, and partly to the increasing demand for the gas for domestic purposes in relatively distant towns of both Kansas and Missouri. Of the several coal smelting plants in this district, only one was operated with anything approaching continuity, and it is relatively small. The obsolete character of the plants, and the increasing price of coal in the immediate neighborhood renders permanent operation impossible. A number of the gas-burning plants have been supplementing their gas supply by the use of fuel oil, but during the year the price of oil for fuel purposes has been advanced sharply and that supply rendered unprofitable.



PRICES OF SPELTER IN 1912.

Illinois, on the other hand, has shown marked activity in the construction of new works. New works in course of construction and partly in operation at the close of the year are those of The American Zinc Co., 4000 retorts, and the Lanyon Zinc & Acid Co., 1600 retorts, both at Hillsboro. All these smelting furnaces are of the familiar Hegeler type, non-regenerative, 800 retorts, and the roasters are seven-hearth Hegeler type, also, all fired with semi-producers. The Edwards furnaces for roasting at the Lanyon plant at Hillsboro proved unsuited for the work and have been dismantled and replaced by Hegelers. The Granby company has under construction near St. Louis a smelting and acid plant, which will probably be in operation late in 1913. Additions are being made to the plant of the Mineral Point Zinc Co. at Depue, and to that of Hegeler Bros. at Danville.

In the Eastern territory the Grasselli Chemical Co. has completed new roasting plants at New Castle, Pennsylvania, and Canton, Ohio, and has added to the capacity at Meadow Brook, West Virginia.

Smelting Furnaces.—No marked advances have been made in the metallurgy of zinc during the year. With one exception, all the smelting furnaces built during the year were of the familiar Hegeler type; long, unregenerating furnaces, with from 300 to 400 retorts to each side, four and five rows high. The exception was the plant of the Mineral Point Zinc Co., which is erecting the regenerative or Siemens type furnaces. An interesting consideration at the present time concerns the relative advantages of the two types of furnace. Granting that the metallurgical results are equally good from the two types, the advantages and disadvantages of each may be summed up as follows:

Hegeler type:

(1) The construction cost is low, as the furnace is a simple enlarged flue, with no regenerative chambers or expensive gas producers.

(2) The labor cost is low, owing to the method of operation, which may be called end to end charging, and progressive operation of the furnace.

(3) The quality of fuel used may be of the lowest grade, as in the furnaces and producers that I first developed and which are in successful use in Illinois, only the cheapest grade of screenings is used.

(4) The disadvantages of the greater quantity of fuel, which may be serious in the case of higher fuel costs. This may be offset by the use of waste-heat boilers where there is a demand for a steam supply in excess of that normally required for zinc works.

Siemens type:

(1) High construction costs, due to regenerative chambers and costly producers.

(2) High labor cost, due to the bottom to top method of charging.

(3) Higher grade coal, as until recently, at least, the use of low-priced screenings has not been attended with success. It would seem that some of the new types of continuous feed, automatically poked producers may possibly solve this in favor of this type of furnace.

(4) The advantage of a very much smaller consumption of coal per ton of ore charged, the amount being in most cases only 50% of that used on the Hegeler type.

The type of furnace to be selected is therefore to be determined by the labor conditions and the permanent ore supply.

Roasting.—In roasting furnaces, for coal fire and with an acid plant attachment, only the Hegeler kiln is being constructed today. The one case where another furnace was tried it proved a failure, and it is probable that for practice in this country at least, the Hegeler kiln is established for some time, notwithstanding high labor and maintenance.

Concentration.—In the concentration of zinc ores in the Joplin and Wisconsin fields the well known practice of jigs and tables, supplemented in the latter district with magnetic methods for the removal of the iron, has not been changed. In fact, the results obtained by this method have been remarkable, both in cost and in efficency of operation. The same degree of success, however, has not been met in the concentration of the more complex ores of the Rocky Mountain region, as there the mixtures of minerals encountered, and their extreme fineness and condition of dissemination in the rock, have rendered necessary a complexity of method and a refinement of operation making a low cost and high recovery impossible. I have been engaged in the solution of a concentration problem where the principal constituents of the ore are (1) galena, (2) pyrite, (3) chalcopyrite, (4) blende (both in the true sphalerite or 'rosin jack' and the so-called 'black jack'), (5) fluorite, (6) calcite, (7) quartz, (8) country rock. All except the last contain silver and gold. Success in concentrating this ore was only attained by methods specially adapted to the ore itself, and only after many costly experiments.

Flotation.—The progress of flotation methods for concentration of zinc ores has not been great in the United States. One mill at Murray, Idaho, is floating zinc sulphide from the lead-mill tailing, and producing a zinc product of good grade. It is there supplementary to wet concentration. There is likewise a small mill in Utah working on zinc ore. The largest plant up to date in this country making use of flotation is that of the Butte & Superior, and this has not been conspicuously successful; in fact, it is said that the mill is being remodeled and flotation discarded, at least for the present. I have made flotation experiments on most of the important zinc ores of the country, and can say without hesitation that many of them are adapted to beneficiation by the process: but, and here is the most important consideration, the methods adapted for the work must be varied to suit the ore in question, and this variation cannot be predicted in advance, nor from any chemical or visible characteristic of the ore. In some cases the mineral will be floated in a scum or foam; in others advantage may be taken of surface tension. This much can be said, however, that for the separation of a pure, or nearly pure, zinc sulphide from most of the various rock or gangue materials, the process is one of great promise when in competent hands, and designed to omit the particular ore.

Federal Administration of the Public Lands

By W. C. Mendenhall

*The Department of the Interior has a wide variety of functions to perform. It includes in its organization such widely diversified bureaus as the General Land Office, the Office of Indian Affairs, the Pension Office, the Patent Office, the Geological Survey, the Reclamation Service, and the Bureau of Mines, and under its jurisdiction fall the National Parks and Monuments and various eleemosynary institutions within the District of Columbia. It is associated in the minds of the Western public, however, primarily with public lands and the natural resources which are a part of these public lands. In general, this association is correct, although there is one important exception to the general truth that the Department of the Interior has administrative responsibility for the public domain. This exception relates to the National Forests. Their administration has been transferred by Congress to the Department of Agriculture, so that the Department of the Interior has no responsibility except in the administration of such laws as affect title to the forest lands.

Responsibility of the Departments

It is constantly to be remembered as well that the Department of the Interior, like all of the executive departments, is an administrative organization. It is not a law-making body, and has therefore but little opportunity for the expression in its administrative action of such opinions and beliefs as its officers may hold upon conservation or other policies. It acts purely by the mandate of Congress, and its functions are to carry out the will of Congress as expressed by statute. Congress, in turn, it must constantly be remembered, is representative of the people of the United States and is presumed to have expressed the will of the people in the statutes which it has enacted. The great mass of the work done by any Department is simply the administration of the ordinary statutes which impose certain duties upon the officers charged with their enforcement, without granting to those officers any choice as to the law itself. Wher., therefore, an attempt is made to define or to discuss the policies of the Department, it is to be borne in mind that only in the administration of those statutes which grant discretionary powers or permit of various constructions and leave to the Department or its officers a choice between different types of action, is there opportunity to develop and to express a Departmental policy. Whenever the Department administers rigid statutes which grant to it no discretion, then a discussion of the action of the Department becomes a discussion of the action of Congress, whose laws the Department is enforcing; for, of course, policies are expressed chiefly in law-making and, to a minimum extent, in law administration.

*Abstract of an address prepared for the California Miners' Association with the approval of the Secretary of the Interior.

The chief differences that might be expected in Departmental administration are differences in the zeal and energy with which the laws are enforced, but to my mind there is actually little difference in these respects between any two recent administrations. The secretaries and assistant secretaries are always earnest and busy men, devoting themselves energetically, and often at great financial sacrifice, to the problems of the Department. Usually, however, the particular type of problem that is to the fore differs from one administration to another. Under the administration of Mr. Hitchcock, for example, the chief problem in the public mind and before the Department was that of the prevention of land frauds. Under Mr. Garfield and Mr. Ballinger the principal problems, perhaps, were those which arose in connection with the Reclamation Service and the public coal-lands. Mr. Fisher, as secretary, is endeavoring to solve important problems connected with the public water-powers and the mineral lands generally, but in all cases the actual task has been that of administration of the law as it is. If past laxities are discovered and corrected, a protest of greater or less volume, depending upon the publicity that can be secured by those who are fostering the protest, is usually heard. They are apt to take the position that the Secretary for the time being is adopting radical policies, or placing new and unwarranted construction upon the laws.

Lands, Minerals, and Water

The principal public resources with whose administration miners are concerned, and with which the Department of the Interior deals, are the public lands, the minerals within those public lands, and the waters which flow over them. The agricultural lands are disposed of under the various homestead laws, the desert land act, the Carey Act, and the Reclamation Act, and the various selection acts under which certain sections are granted to states for the support of schools or other purposes, or to railroads to assist them in construction, or to those who have served the Nation in some particular way, as the old soldiers who are given special homestead rights that do not belong to other citizens. These selection acts give rise to the 'scrip' which is purchasable, and can be used by the purchaser as well as by the original beneficiary. The laws under which these agricultural lands are distributed provide that they shall be non-mineral in character, and it devolves upon the Department to determine whether they are of the character contemplated by the law. The questions involved here are, generally speaking, not questions of policy, but of fact. To be sure, the facts may be difficult of determination and may involve matters of judgment, but nevertheless a conclusion once reached by the appropriate Departmental officer as to the actual facts in the case, the operation of the law thereafter is automatic.

One of the most important of the laws affecting the mineral resources and one whose administration requires the exercise of discretion by the administrative officers is the so-called withdrawal act passed on June 25, 1910, and amended in important particulars August 24, 1912. This act authorizes the President to reserve public lands for power-sites, irrigation, classification of lands, or any other public purpose to be expressed in the order of withdrawal, and the lands thus withdrawn cannot be acquired except under the mining laws applicable to metalliferous minerals. This power has been widely exercised by the President. Lands believed to contain coal have been withdrawn from entry until they could be examined and their coal value determined. Lands believed to contain valuable phosphate deposits have been withheld from entry pending the passage of an act for their disposition. Oil and gas lands have been similarly treated. Water power sites outside of the National Forest, and to a very limited extent within them, have likewise been withdrawn pending appropriate legislation. In the case of coal lands for whose disposal there exists an adequate law, restoration has followed withdrawal as soon as the necessary examination could be made and prices based upon the quantity, depth, and quality of the coal present could be placed upon the lands. After restoration the lands are open to acquisition precisely as if never withdrawn.

Coal Lands

I believe that the great majority of the citizens of the United States approve unqualifiedly of the present administration of the coal land law in connection with the withdrawal act, but protests are still heard occasionally from those who continue to believe that government lands containing highly valuable coal deposits should continue to be sold as they were prior to 1906, at the lowest possible legal price. Mr. Fisher's own attitude in this matter, which is the attitude of Mr. Garfield and Mr. Ballinger whose policies he is continuing, has been clearly set forth in certain correspondence with F. W. Mondell,† who has opposed, not the principle of valuation, for that seems too well established for opposition even by the most emphatic opponents of the present administration of the public coal lands, but the application of that principle by the placing of prices which in a few instances are as high as $400 or $500 per acre.

In considering the coal-land policy it is also essential to remember that returns from sales of government lands, whether mineral or nonmineral, are added to the Reclamation fund and thus are utilized in irrigation development in the West. I assume, however, that no one is strongly opposed to the present coal-land policy. Its net results seem to be what they are intended to be, namely the prevention of large purchases of valuable lands at low prices for speculative holding, without discouraging purchase for immediate development whenever market conditions shall require that development. It is to be remembered also in considering the government withdrawal policy in its relation to coal lands that by virtue of the acts of March 3, 1909, and June 22, 1910, these lands even during the period of their withdrawal are not withheld from agricultural use. Settlement proceeds upon withdrawn as well as upon unreserved lands, the difference being that surface title is granted on the reserved lands whereas title without reservation of mineral is granted in the case of the unreserved lands.

Phosphate Lands

The situation in relation to the phosphate lands of the West differs from that which prevails in the coalfields. The discovery of the Western phosphate fields is a relatively recent event and Congress has not as yet decided upon legislation that will be appropriate for the encouragement of the phosphate mining industry. In the absence of any adequate legislation the lands are simply withheld from entry awaiting such disposition as Congress may make of them. No law permitting surface entry on those withdrawn lands exists so that their withdrawal takes them out of the range of agricultural settlement. This is a matter of regret to the Department, but the interference with agriculture is nominal rather than real, because the great body of the lands really valuable for agriculture that have been included within the phosphate reserves were entered or patented before the phosphate withdrawals, and are therefore unaffected. The remaining lands in most instances have little agricultural value. Perhaps here and there a subdivision exists which should be available for agricultural entry. It is withheld from such entry so long as the withdrawals are in force, and it is presumed they will remain in force until adequate legislation providing either for the leasing of the phosphate or for its sale upon some such plan as that provided for coal lands shall have been enacted.

Oil and Gas Lands

The oil and gas situation, except in the state of Utah, is not unlike the phosphate situation. As is well known, oil lands are acquired under the anachronistic placer law devised in California for the acquisition of alluvial gold deposits. This latter is most inappropriate as a provision for the acquisition of deep-lying fluid and gaseous deposits, and in aid of more appropriate legislation the known oil and gas lands in the public land states have been withdrawn from entry. This withdrawal, like that of the phosphate lands, prevents agricultural settlement except in the state of Utah. Congress at its last session provided a separation act by which surface title upon oil and gas lands can be acquired in that state. The bill as first drawn was universal in its application, but during its consideration a strong protest was received from certain of the California oil interests against permitting agricultural entry upon the surface of the California oil lands. It was stated in this protest that the California lands were desert in character; that they had no agricultural value, and that they were useful solely in the development of the underlying fluid and gaseous fuels; that to permit agricultural entry would merely permit further complications in an already compli-

†*Mining and Scientific Press*, Oct. 7, 1911.

cated situation so far as titles are concerned. Because of this attitude on the part of the California citizens, the law as finally passed was limited in its application to the state of Utah. Whatever interference there may be with agricultural entry by the withdrawal of oil lands is therefore to be attributed to the opposition of the people themselves.

Partly as a result of the withdrawals and partly in recognition of the need of more adequate legislation, a number of measures have been proposed in Congress for the disposition of the oil-bearing public lands or of the deposits within those lands. The Department when called upon for reports upon these measures has recommended the passage of a leasing act. It advocates first a provision which will authorize the issue of exploratory permits that will safeguard the permittee by giving definite rights upon the territory included within his permit during the period preceding discovery. It is believed, for instance, that the permit should be granted for a short fixed period to a definite area with due conditions as to diligent prosecution of exploratory work, the permittee being protected in his exclusive possession during the life of the permit, if these conditions are fulfilled. At present the oil operator does not come within the cognizance of the federal law until he applies for patent. He can not legally apply for patent, indeed has no legal location, until he has made discovery, and in the deep territory of the California oilfields discovery may involve a year or two years' work and the expenditure of several thousand dollars.

Temporary Prospecting Permits

During prospecting he has no adequate protection under the law either for the property included in his claim or for the capital that he has invested in the attempt to develop it. This is theoretically a most anomalous situation and has been made workable at all only by the fact that operators and prospectors here by a sort of unwritten law mutually agreed to respect one another's filings. But even this extra-legal device is not by any means always effective. It is not rare even now in the California oilfields to be held up by a gun-man who is protecting a claim from possible jumpers, even though the protector may himself be of this class. Everyone agrees that this situation should be corrected, and it is believed that it would be corrected by a provision for an exploratory permit to be followed later by a lease or title. It is the Secretary's belief that lease, not title, should be granted. Much the greater part of the oil development in the United States is effected on the leasehold basis, and were the Government to grant title, lands which it patented to the oil claimant would in a large proportion of cases be developed not by him but by a lease from him. By leasing directly at a moderate royalty the Government would retain ownership and the highly desirable power to readjust to future conditions as they may develop, which power it surrenders when it grants title in fee. The income which it would receive would undoubtedly be greater under the leasehold system than under the present system, and this increased return is a matter of consideration, although it is not regarded by any of the advocates of government leasing as the principal reason for the advocacy of the system. Its chief argument is control, the power which that control gives to regulate and perhaps prevent monopoly, all of which in turn is intended to benefit that friendless waif, the universal victim of all commercial exploitation—the ultimate consumer.

Water Powers

Another phase of what may be considered government policy, in that it represents the exercise of administrative discretion under a statute, is the withdrawal of lands valuable for water power by virtue of the authority contained in the withdrawal act. These withdrawals, like so many administrative acts, are bitterly opposed in some quarters and equally earnestly advocated in others. They, like the oil and phosphate withdrawals, are made in aid of legislation. The statute books at present contain no law which provides adequately for the acquisition and the utilization of these lands. The only law providing primarily for power development is the act of February 15, 1901, which merely authorizes the Secretary of the Interior, in the public lands outside of the forest reserves, and by a later act, the Secretary of Agriculture within the forest reserves, to issue permits revocable at will. Government officials recognize fully that a permit of this type does not offer satisfactory security to the large capital investments necessary in the construction and operation of a modern power plant. The present Secretary of the Interior upon many occasions has earnestly advocated the passage of a law which will permit the issuance of a permit for a definite period of years with provisions for readjustment of rates at appropriate intervals, in order that capital may be relieved of the menace implied in the fact that its basic title must in terms be revocable at will. No such law, however, exists, so that the Department is reduced to administering water powers as best it can under the present law. The Department of Agriculture has had in existence for a few years a set of regulations based on this law, under which power developments are provided for within national forests, and large capital investments have been made on the terms laid down.

New Regulations

On August 24, of this year, the Secretary of the Interior approved a similar set of regulations for power development on public lands outside of national forests and more recent hearings have been held in Washington at which all of the more important power interests were invited to send representatives, the purpose of these hearings being to secure criticisms of the regulations and to determine as fully as might be their practicability. Pending their preparation, permits were not issued on the public domain outside of the national reserves, except in special cases. With their approval, however, the issuance of permits will be resumed and power developments can continue on practically the same terms as those which now prevail in national forests. Meanwhile, the lack of provision for ade-

quate tenure in the power act has resulted in many attempts to secure power rights on the part of those who contemplate developments under other laws.

The irrigation act of 1891 has been a favorite vehicle for power applications. Numbers of applicants have appeared before the Department and have filed their maps of rights of way for conduit lines and reservoirs under the irrigation law of 1891, which inspection by engineers clearly indicated were desired not for irrigation development as this act requires, but for power development. The Department in such cases has of course been compelled to refuse the applicant the rights for which he asks and many of the attacks upon the so-called water-power policy of the Department have been fostered by those who have thus been refused the Department's sanction in their attempt to use the irrigation law for a purpose for which it was not intended. Another law to which resort has frequently been made is the building stone placer law. Filings are often made under this law upon areas valuable as intakes for power canals, or for the construction of power houses and the power purpose of the applicant is clearly manifest. The duty of the Department in the administration of the laws enacted by Congress compels it to refuse to aid in this misuse of the laws of the nation, even while recognizing that the attempts are due at least in some cases to the fact that the laws now in force are scarcely adequate for the accomplishment of the legitimate purpose of the applicant.

Attitude of the Secretary

Mr. Fisher's general attitude on the question of the principles that should control development of water powers is set forth in his testimony before the National Waterways Commission on November 23, 1911. There he stated that he believed that the Federal Government should retain control of the whole general subject, both as it relates to water power in the navigable and in the non-navigable streams of the federal domain, basing his opinion upon the fact that so many of the streams are of interstate and national character that the Federal Government can not escape the obligations which rest upon it, for if it does not exercise jurisdiction no adequate jurisdiction can be exercised, the states being limited in their action by their own boundaries. Mr. Fisher set forth in this hearing and at the hearing on the water-power regulations during November of the present year, his belief that there need be no conflict, rather that there should be close co-operation between the states and the nation, each operating within its appropriate sphere in water-power control. His attitude appears to be that the states should control service and rates, and that the territorially broader federal powers should be invoked chiefly to assist the states, and for use in those cases where the state does not act or cannot act because state boundaries are crossed and jurisdiction is lost. In other words, the two powers, state and federal, will supplement each other to the final end of securing the safety and certainty necessary for development and the protection necessary to the final user of the power.

(To be Continued)

Tin Dredging on Seward Peninsula

In 1912 the dredge of the York Dredging Co. on Buck creek had a good season, slightly in excess of 175 tons of concentrate being shipped as against 93 tons in 1911. This concentrate averaged 68% metallic tin. From the success of this boat and the high prices of tin prevailing, considerable interest has been excited on Buck creek and in other areas in Alaska supposed to contain tin in profitable quantities. New discoveries on Tuttle river will be more carefully investigated during 1913 with the view to building a dredge. The York dredge has only between two and three years' life on ground owned or leased by the company, but it is not improbable that a satisfactory arrangement will be made with the owners of adjoining property which will give the dredge several additional years.

THE BUCK CREEK DREDGE.

In addition to dredging cost, the cost of handling tin concentrate is a matter that is not always clearly understood by those interested in prospective tin areas, some figuring the quoted price of metallic tin as directly applicable to the concentrate recovered and also overlooking many of the charges for transportation and sale. To those desiring more careful calculation the following information furnished by Walter Johnson will be of interest. On a shipment of practically 16 tons of concentrate, the cost of freight, insurance, brokers' charges, etc., amounted in round figures to $40 per ton, divided as follows:

Freight to Nome	$10.00
Freight Nome to Seattle	4.00
Freight Seattle to Liverpool	8.50
Sale charges at Liverpool	7.50
Insurance	10.00
	$40.00

This equals 2c. per lb. of concentrate. This would be about 3c. per lb. of metallic tin. The cost of dredging at the York dredge averaged 26c. per yd. The ground is from 4 to 6 ft. deep. In addition to operating cost the prospective investor should of course consider the cost of the property or the royalty, and of amortizing the plant. Aside from this operation, only minor amounts of tin were produced in the United States in the year just closed.

Secondary Sulphide Enrichment of Ores—I

By C. F. Tolman, Jr.

Considerably more than one-half of the copper of the United States is won from ores whose commercial grade is the result of 'secondary sulphide enrichment,' and none of the larger mines of the Southwest could pay dividends had the grade of their ore not been raised by this process. Since this enrichment is caused by the chemical action of water, trickling downward from the surface through fractured or porous rocks or concentrated in the stronger fissures, the geologist or prospector will investigate the character and structure of the rock which he suspects of having undergone this process. A decomposed porphyry or schist allows a diffused downward circulation which penetrates the entire mass of the rocks, and if the descending solutions are copper bearing, and a precipitating agent is present below the water-level, we may confidently expect a more or less horizontal sheet of disseminated copper ore, the upper surface of which will generally be at the level of the ground-water. Strong fissures in a less permeable country rock will develop lode deposits rather than blankets, the strength of the fissure and the force of the downward flow governing the depth to which these deposits will extend. No trained engineer or experienced prospector would expect to find a disseminated chalcocite deposit in a limestone, because (for reasons explained later) precipitation occurs as layers around kernels or masses of original sulphides and not around innumerable sulphide specks as in the schists or porphyries.

Topography governs both downward percolation of water and the amount of rock exposed to leaching above the water-level, and therefore the investigator may be called upon to study not only the relation of the present topography to subsurface drainage, but to reconstruct past topographies, and to determine whether or not the rates of erosion and leaching have been so adjusted that a considerable thickness of copper-bearing rock has been worked over.

General Nature of Process

The process involves the oxidation and solution of the sulphides above the water-level as well as the deposition of the sulphides below that level, and therefore it is necessary to examine the speeking, staining, etc., of the surface rock in order to determine whether or not such specks are the remains of metallic sulphides or whether they are the residues of iron-bearing silicates such as biotite, hornblende, etc., the leaching of which could not give rise to copper enrichments.

On the other hand, secondary sulphide enrichment has been assumed in cases where it has not occurred, and the exhaustion of rich sulphide ore at moderate depths below the water-level has been predicted where such prediction was not justified by the evidence or verified by later developments.

In view of the importance of the subject, it would seem that the methods of investigating secondary sulphide enrichment should be made available to prospectors and mining engineers. The literature (see selected bibliography) does not adequately present either the theory of this subject or its practical application. The value of W. H. Emmons' paper on the outcrop of orebodies[1] published in this journal has encouraged me to attempt a similar practical presentation of the criteria by which the value and extent of secondary enrichment may be judged.[2]

Definition of the Process

Secondary sulphide enrichment involves three processes: (1) The oxidation of the metallic sulphides; (2) the solution of these chiefly as sulphates, chlorides, or bicarbonates; and (3) the precipitation of the metals in solution in the form of secondary sulphides (*a*) by reduction of the sulphates to metallic sulphides by carbonaceous matter, or (*b*) precipitation by means of hydrogen sulphide, or (*c*) reaction of the metallic salts with the unoxidized sulphides below the water-level, the latter going into solution as sulphates (or other salts) and the former precipitating as sulphides. In the broadest sense secondary sulphide enrichment includes deposits of any sulphide precipitated in any way out of the descending meteoric waters which owe their metallic content to the leaching of the overlying rock. Under this definition we would include replacement of organic material by copper, iron, lead, and zinc sulphides, copper sulphide deposits in the sandstones of the Permian[3] and Triassic in various parts of the world, and of copper, lead, zinc, vanadium, uranium, radium, arsenic, antimony, and other minerals in the La Plata sandstone of Colorado and Utah.[4] The circumstance, however, that the leaching is followed by prompt precipitation directly under the leached zone, separates these deposits from the lead and zinc deposits of the Mississippi basin,[5] where there is considerable migration of solutions before precipitation and the close relation of impoverished to enriched areas is not evident.

Secondary sulphide enrichment becomes of greater economic importance in a more restricted sense; that is as an enrichment of a low-grade sulphide orebody.

[2]Since this article was sketched, I have learned that W. H. Emmons is writing a small treatise on secondary sulphide enrichment to be published by the United States Geological Survey. We shall expect a monograph worthy of the importance of the subject. F. L. Ransome has completed his detailed studies of the Ray disseminated copper deposits and the re-survey of that portion of the Globe Quadrangle embracing the Miami-Inspiration ore-zone. These publications, with the detailed report on the region covering the Chino mines, New Mexico, will furnish data of greatest importance to those engaged in the critical study of secondary enrichment.

the added metallic content coming from the leaching of the upper portion of the vein itself, or from a system of veins, or from a general metallic impregnation of the overlying rock.

Original, Primary, and Secondary Minerals

In any ore deposit, there may be present three sorts of minerals; (*a*) the original minerals of the rock, (*b*) minerals introduced by vapors and waters of deep seated or igneous origin, and (*c*) those contributed by descending surface waters. In this paper these will be called respectively original minerals, primary minerals, and secondary minerals, although unfortunately this nomenclature has not always been adopted. The processes of ore formation are often continued and complex. Veins may be repeatedly re-opened and the activity of the mineralizing waters renewed, and the deposit may receive repeated enrichment from ascending solutions. It is unfortunate that these have been called secondary enrichments.[6] They should be spoken of as primary enrichments, leaving the secondary for the rearrangements caused by meteoric waters.

Zones Developed by Reworking Deposits

The processes of oxidation, solution, and precipitation develop five zones (Fig. 1), in approximate orientation with both the surface of the ground and the underground water-level, although all of them may not be distinctly developed at each locality. These are as follows:

I. The Surface Zone of Complete Oxidation.—Here oxidation has been carried to an extreme. The so-called iron cap often appears at the surface and is composed of limonite and hematite, often with much residual silica. Residual gold may be concentrated here, a relative enrichment in respect to that metal being brought about by the removal of the soluble mineral constituents of the deposit. Silver chloride is often present, especially in desert regions[7] where the ground-water is rich in chlorine, forming the relatively insoluble silver chloride and other haloid compounds. Occasionally the somewhat insoluble lead silicates, carbonates, and sulphates are found in the surface zone, and less often the insoluble oxidized compounds of zinc and copper. These extremely oxidized crusts may grade into the next zone, or the oxides may continue to the water-level.

II. The Zone of Complete Leaching.—A few feet below the surface, or a score of feet at most, there is generally found a thoroughly leached and decomposed zone containing either lean ore or only traces of the metals which form soluble salts, although the gold, and less often the silver, may continue through this zone.

III. The Zone of Oxide Enrichment.—Just above the sulphide zone the minerals may be only partly oxidized, occurring as native elements, oxides, carbonates, and silicates, which, when brought farther up in the oxidized zone by the erosion of the surface, may then go into solution under further attack by the oxidizing solutions. If the water-level is being slowly depressed, the upper portion of the enriched sulphide zone will be attacked continually, and very rich oxidized ores may thus be developed. Especially in limestone, rich oxidized ores are apt to be formed, because the limerock tends to neutralize the free sulphuric acid formed from the oxidation of pyrite and which is the most active of the reagents causing the complete decomposition of the oxides. The carbonic acid gas forms the somewhat insoluble carbonates that collect with the oxides in this zone. This zone may be lacking where leaching has been long continued and the rock is pervious to descending waters.[8]

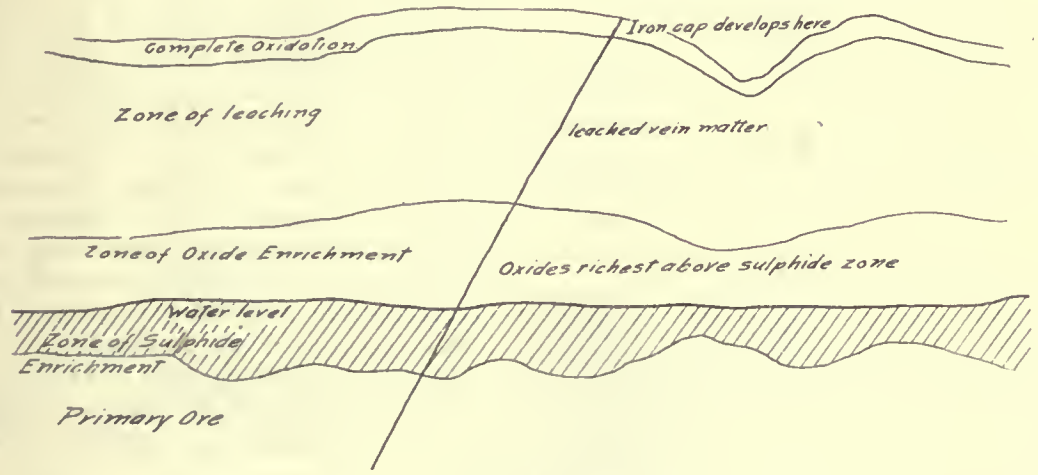

FIG. 1.

IV. The Zone of the Secondary Sulphides.—In most cases the upper limit of the zone is the water-level. Some have gone so far as to assume that this boundary always holds, but important exceptions are noted later. The position of this zone therefore is determined by the underground water-level and varies from a few feet to 400 to 500 ft. below the surface for semi-arid and elevated regions, and the zone may be depressed exceptionally to depths exceeding 1000 ft. where conditions of open fissuring exist.[9]

[9] Hough, George J., *Mining and Scientific Press*, p. 40, 1912.

The thickness of the zone is extremely variable, the rich chalcocite forming a crust at water-level only a few inches thick in some of the copper mines in eastern United States, while at Butte the zone has an extreme thickness of nearly 2000 feet.[10]

V. The Zone of Primary Sulphides.—The zone of secondary sulphides is bottomed in a most irregular manner, enrichment often penetrating to great depths along a vein, the structural features of which permit a deep descending circulation, while a neighboring vein may develop only a thin or perhaps no secondary deposit.

Even in a permeable, thoroughly fractured rock the dying out of enrichment is so gradual that for practical purposes an artificial line is drawn, ore carrying less than a certain percent of copper being considered as primary ore, although it may show specks of secondary sulphides. Although difficult to define the boundary is none the less real. Below this boundary further variations in value will be those of the primary mineralization which may or may not be of economic value.

Chemistry of Secondary Sulphide Enrichment

The exact chemical equations governing the oxidation, solution, and secondary precipitation are not known and perhaps will never be written.

Any equation given for a reaction of this character can only be a generalized statement of final results, much as the equation $H_2O = 2H + O$ written to explain the hydrolysis of an acidulated water solution does not take into account the complicated reactions that have been proved to take place. Knowing the end products of the reaction and the most important mineral constituents in the solution, we choose the simplest chemical equation expressing the reaction.

OXIDATION

The first process in the chain of events that culminate in the precipitation of the secondary sulphides is the breaking up of the insoluble sulphides which takes place above the water-level, where moisture and oxygen can attack them. The order in which these yield the oxidizing action has been variously stated: Ries[11] giving the order of decomposition as arsenopyrite, pyrite, chalcopyrite, blende, galena, chalcocite, and tetrahedrite. Beck[12] gives marcasite, pyrite, pyrrhotite, chalcopyrite, bornite, millerite, chalcocite, galena, zincblende. No one order covers a majority of cases, but many changes will be brought about by variations in the attacking solutions, which may be acid, neutral, or alkaline. Oxygen from the air may be assisted by strong oxidizing agents such as ferric salts and where a mixture of sulphides are attacked, the composition of the mixture is important. A notable exception to the given order is found in the disseminated chalcocite deposits in altered porphyry. Descending solutions attack the sooty chalcocite dissolving out the copper and leave behind a residual pyrite zone.[13]

Galena is especially resistant to oxidizing attack because it tends to develop a film of insoluble lead sulphate that protects the interior of the crystal, and the result is that, especially in arid regions, residual galena is found at the surface.

The relative resistance to oxidation and solution may be a factor of importance affecting the development of the secondary sulphide deposit. If decomposition is slower than mechanical erosion the latter may sweep the sulphides away before their metallic contents are leached and carried downward. The chemical and physical composition of the gangue minerals may be more important than that of the sulphides. Many contact deposits containing copper sulphides are intergrown in such a dense gangue of garnet, epidote, and quartz that the oxidizing solutions have great difficulty in getting at the sulphides.

Oxidation of Pyrite.—Pyrite is the predominant sulphide of most primary ore deposits, and therefore its oxidation products form the chief reagents by which the enrichment processes are brought about. The oxidation of pyrite may be written in the following simple manner:

(1) $FeS_2 + 4O = FeSO_4 + S$

(2) $FeS_2 + 6O = FeSO_4 + SO_2$

(3) $FeS_2 + 7O + H_2O = FeSO_4 + H_2SO_4$

These three reactions correctly represent geological conditions, although the oxygen may not come directly from the dissolved air, but from oxidizing agents. For instance, as suggested by equation (1) sulphur has been found in many orebodies at the water-level and at the bottom of the zone of oxides.[14]

Mr. Gormley proved in the laboratories of the Anaconda Copper Co., Butte, Montana, that SO_2 is actually produced in the oxidation of pyrite. The presence of H_2SO_4 in mine water, as a result of the rapid oxidation of pyrite, exposed to oxygen by means of mine workings, is so well known that further mention is not necessary.

Oxidation of $FeSO_4$ and the Role of Ferrous and Ferric Salts.—The oxidation of ferrous sulphate to ferric sulphate is concisely represented by the simple equation

(4) $2FeSO_4 + H_2SO_4 + O = Fe_2(SO_4)_3 + H_2O$

Excess sulphuric acid is generally present as shown in the preceding paragraph, and the oxygen comes directly from the atmosphere, as this reaction takes place above the water-level. Ferric sulphate is not particularly stable, especially close to the surface, but at deeper horizons ferric sulphate with ferric chloride, and perhaps mixtures of other ferric salts, stay in solution, becoming active oxidizing solutions at depth below the surface. The breaking up of the ferric sulphate at the surface is perhaps assisted by the evaporation of the solution, the product being a mixture of the various hydrated oxides of iron and hematite forming the well known 'gossan' or 'iron cap', as follows:

(4a) $2Fe_2(SO_4)_3 + 9H_2O = 2(Fe_2O_3).3(H_2O) + 6H_2SO_4$

The oxidizing action of ferric sulphate below the surface is generally recognized. For example, ferric

[10]For the latest data on the question as to what portion of the Butte chalcocite may be primary, see Chas. T. Kiel's 'Conditions of Mineralization in the Copper Veins at Butte, Montana, *Economic Geology*, Vol. 7, pp. 35-83, 1912.

[14]Lakes, A., 'Vulcan and Mammoth Chimney Mines.' *Trans. Amer. Inst. Min. Eng.*, Vol. 26, pp. 440-448, 1896.

sulphate reacting with pyrite may be expressed

(5) $FeS_2 + Fe_2(SO_4)_3 = 3FeSO_4 + 2S$. and

$2S + 6Fe_2(SO_4)_3 + 8H_2O = 12FeSO_4 + 8H_2SO_4$

It is well to remember that in the presence of water one molecule of ferric sulphate may break up into two molecules of ferrous sulphate, one of H_2SO_4 and free one atom of oxygen to attack oxidizable substances.

An important action of ferrous and ferric salts is their rôle as solvents and precipitants of gold. Discussion of this reaction is made necessary by the valuable contribution of W. H. Emmons.[15] It appears that some chlorine and manganese salt must be present, and the reversible reaction may be written

(6) $Au + 3FeCl_3 \leftrightarrows AuCl_3 + 3FeCl_2$

Looking at the right hand member of the equation it will be seen that if there is any ferrous salt (or any other reducing agent for that matter) the reaction will take place toward the left, and gold will be precipitated immediately, on account of its insolubility. If, however, a strong oxidizing agent, such as a manganic salt, is present, the ferrous salt will be destroyed as soon as formed, the solution of the gold continuing as long as the ferrous salt is oxidized. Theory suggests, however, that gold will not be carried very far down, for reducing agents, such as carbon, organic matter, or sulphides, will soon be encountered, and the gold precipitated immediately. This reaction is especially important in bringing the small amounts of gold, distributed in an eruptive rock, and containing manganese, to the surface. Among many examples that I have noticed, the best one of such action is to be found in the 'gold mirrors' of the 'Gold Mountain' fake in the Galurios mountains, Pinal county, Arizona. This deposit is in a sheared rhyolite, containing manganese, as shown by the stain on weathered surfaces. The gold occurs as plates along cracks, startling in appearance. The discoverer of the mine was employed by the management to break the rock along the cleavages, and thus expose the gold mirrors to the prospective investors. The water circulation in the body of the rock is shown beautifully by the concentric streaks of brown and white. The sketch opposite is taken from my note book (Fig. 2). The concentric rings are brown to black from concentrated iron and manganese, and where the manganese stained band intersects the surface of a fracture, the gold plate is precipitated either by evaporation or reaction with solutions in the fissure. For further discussion of the solution and precipitation of gold, the reader is referred to the contributions of Mr. Emmons cited above.

SECONDARY SULPHIDE SOLUTIONS

History.—Secondary sulphide enrichment is popularly supposed to have been discovered by C. R. Van Hise (from the theoretical side), and S. F. Emmons and W. H. Weed[16] (from the observational side during their examination of the Butte ore deposits). The idea, like most so-called discoveries in science was really slowly evolved, and not discovered by these men. The process was certainly outlined as early as 1893 in the text-book on ore deposits by Fuchs and de Launay,[17] and was recognized as a factor in the formation of Southwestern ore deposits[18] before announced by Weed. The idea was but the extension of the long accepted fact of the precipitation of sulphides from sulphate solutions by reducing agents, such as bituminous matter, H_2S, etc. On the chemical side, Stokes says[19] that the precipitation of soluble metallic salts, by insoluble

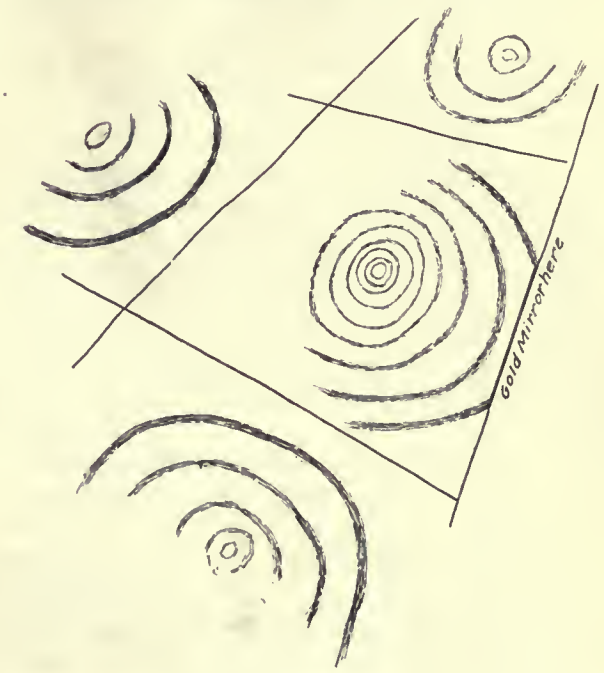

FIG. 2.

sulphides, was investigated as early as 1837 by Anthony, and later in an exhaustive research by Schürmann, the latter established the famous 'order of precipitation' of the sulphides, the importance of which will receive notice later. This should be called 'Schürmann's Series'. In 1899-1900 I produced artificial chalcocite by treating nearly barren pyrite with a solution of copper sulphate and SO_2, the latter, as stated above, being formed as a first product of pyrite decomposition and the experiment imitated Butte conditions as closely as possible. The result was that beautiful films of chalcocite were precipitated on, and probably in part replacing, the pyrite, and these results formed the basis of H. V. Winchell's[20] contribution to the subject.

Subsequent chemical investigation has brought out little to add to the fact, thus proved, that the reaction takes place. Stokes[21] giving the most probable equation by which the reaction takes place, and Wells[22] showing there is a tendency toward the com-

plete precipitation of one mineral before the precipitation of the second takes place.

The so-called secondary sulphide reaction consists in an interchange of bases between a salt (generally a sulphate) of the heavy metals and a sulphide (generally pyrite).

These may be grouped under the following heads:

1. The valence of the precipitated metal is not changed. The precipitant is a mono-sulphide.
2. The valence of the precipitated metal is not changed. The precipitant is a di-sulphide.
3. The valence of the precipitated metal is changed. The precipitant is a mono-sulphide.
4. The valence of the precipitated metal is changed. The precipitant is a di-sulphide.

Under the first head the reaction is one of simple substitution and an example may be written

(7) $Ag_2SO_4 + ZnS = Ag_2S + ZnSO_4$

Reactions of the second class are complicated by the fact that pyrite is a di-sulphide. Take the precipitation of Zn sulphide by pyrite. If we assume that an ion of zinc replaces one of iron we have an excess of free sulphur, or if we write the equation so that all the sulphur unites with the zinc we have an extra ion of SO_4 or in the presence of water $H_2SO_4 = O$. These relations are expressed as follows:

(8) $ZnSO_4 + FeS_2 = ZnS + FeSO_4 + S$

(9) $2ZnSO_4 + FeS_2 + H_2O = 2ZnS + FeSO_4 + H_2SO_4 + O$

While examples of free sulphur in the sulphide zone are known, in most cases the reaction seems to produce the sulphide and sulphuric acid. In the presence of water three oxygen atoms will oxidize one atom of sulphur into sulphuric acid, therefore if we multiply equation (9) by three and add to the product equation (8) and one molecule of water we obtain

(10) $7ZnSO_4 + 4FeS_2 + 4H_2O = 7ZnS + 4FeSO_4 + 4H_2SO_4$

Emphasis is laid on this reaction, because those written by Van Hise[23] and copied in several textbooks on ore deposits, assume the presence of free oxygen, in order to oxidize the sulphur called for in equation (8). It is not probable that free oxygen exists in the zone of secondary sulphide enrichment, certainly not at depth in this zone, and they are not good from the geological point of view.

The further complications arising under cases 3 and 4 are caused by the fact that cupric sulphate is generally precipitated as cuprous sulphide (chalcocite). There are probably many different reactions taking place to produce this result. For instance Stokes[24] has shown that a reversible reaction takes place as follows:

(11) $2CuSO_4 + 2FeSO_4 \leftrightarrows Cu_2SO_4 + Fe_2(SO_4)_3$

Now if any H_2S is present (from the attack of H_2SO_4 on pyrite), the cuprous sulphide Cu_2S (chalcocite) will be precipitated since it is more insoluble than CuS (covellite). The reaction however favored by Stokes, and which may be given his name, may be deduced in the same way we obtained the balanced reaction between pyrite and $ZnSO_4$.

(12) $2CuSO_4 + 2FeS_2 = Cu_2S + 2FeSO_4 + 3S$

(13) $4CuSO_4 + FeS_2 + 3H_2O = 2Cu_2S + FeSO_4 + 3H_2SO_4 + 3O$

Multiplying equation (13) by 3 in order to have the right amount of oxygen to oxidize the sulphur and adding thus to equation (12) we obtain

(14) $14CuSO_4 + 5FeS_2 + 12H_2O = 7Cu_2S + 5FeSO_4 + 12H_2SO_4$

This reaction best expresses the facts as shown in disseminated copper deposits where $CuSO_4$ acts directly on pyrite to form chalcocite, without the formation of residual sulphur. For those secondary sulphide deposits where free sulphur is formed equation (12) is suggested.

There is another equation worth considering, as it was the one I selected as best expressing the reaction governing the formation of chalcocite in the Butte experiments. Since it was found necessary to add SO_2 to produce a satisfactory and rapid precipitation of chalcocite, and as there was reason to believe that this gas was present in the strongly acid solutions at Butte, this gas was assumed to react with the extra oxygen shown in equation (13) which becomes the following:

(15) $4CuSO_4 + FeS_2 + 3SO_2 + 6H_2O = 2Cu_2S + FeSO_4 + 6H_2SO_4$

Weed[25] describes an unusual case where ferric oxide and chalcocite are deposited simultaneously. A reaction covering this case would read

$6CuSO_4 + 2FeS_2 + 4H_2O = 3Cu_2S + Fe_2(SO_4)_3 + 4H_2SO_4$

The ferric sulphate then breaks up into ferric oxide as discussed above.

So far it has been assumed that the copper is in solution as copper sulphate, and that there is an excess of H_2SO_4. This is undoubtedly the case at Butte where the solutions are concentrated and the country rock is granite, but in the disseminated deposits where the pyrite is scattered through an altered sericitized porphyry, or schist, and especially in deposits in limestone, it is probable that alkali and lime carbonates neutralize the solutions, and change the copper sulphate into copper bicarbonate which is somewhat soluble. In an interesting investigation, the results of which have not as yet been published, R. H. Forbes has followed the migration of copper from the tailing from the Clifton, Arizona, concentrators out through the soil of the farms along the Gila river, up into the farm produce and the trees, and from the latter into the mistletoe, which concentrates the copper in itself by robbing the tree of sap and breathing out the moisture, which is of course free from copper. He states[26] that the copper passes through the soil as a carbonate.

Mention[27] has already been made of experiments showing the prompt neutralization of acid solutions when digested with limestone from the Bisbee mines, and the orebodies at this locality show in a beautiful manner how the limestone is eaten away by descend-

ing carbonates of copper, to enrich the pyritic lenses below the water-level.

In the disseminated chalcocite deposits there is a large amount of secondary silicification, and as silica is more soluble in alkaline than in acid solutions, a prompt neutralization is indicated. Further copper silicates and carbonates are found to underlie the sulphide ore, at the Miami, Arizona, orebody; the explanation appealing to me is that the brecciated zone which dips under and cuts off the sulphide ore, contained little or no pyrite, and hence these compounds were deposited rather than the sulphide.

The above discussion is justified by the practical importance of these conclusions. If solutions carrying copper carbonates and silica do not encounter sulphide precipitants, they will not form sulphide deposits at any depth.

The chemistry of copper bicarbonate solutions has not been investigated, but it may be remarked that $Cu(HCO_3)_2$ may be substituted for $CuSO_4$ in any of the equations given above and equivalent results be obtained, iron carbonate forming instead of iron sulphate.

Order of Precipitation of Various Sulphides.—Schürmann's series[28] gives the order in which sulphides are precipitated as follows: palladium, mercury, silver, copper, bismuth, cadmium, antimony, tin, lead, zinc, nickel, cobalt, ferrous iron, arsenic, thalium, and manganese.

This may be interpreted as follows: A solution of silver sulphate will precipitate silver sulphide upon contact with copper sulphide, or any member of the series to the right, but it is difficult for silver sulphide to precipitate copper sulphide. The order will not hold under all conditions, for by 'mass action,' a strong solution of a metallic salt may cause a precipitate at the expense of a member of the series to the left. The order, however, is an important one, the silver in a secondary sulphide enrichment almost invariably being at the top of the zone, the copper extending to depths, and at times zinc sulphide appearing at depth below the copper. Lead sulphide and its oxidized products almost invariably hug the surface in spite of its position in the Schürmann series, because of the insolubility of most of the oxidized products of lead, which makes the downward migration very slow. Zinc on the other hand is often completely eliminated from the oxidized zone by leaching, leaving perhaps a 'free-milling' gold ore at the surface, which changes promptly at the water-level to a refractory zinc ore.

Mineralogy of Secondary Sulphides.[29]—The reader will readily appreciate the importance of determining the 'critical minerals' of the secondary sulphide zone, *if such exist.* However, as there is only one mineral, covellite, that up to date has been described only as secondary, and as this is not a common mineral and as some future investigation may find even this mineral to occur as a primary mineral, a group of minerals characteristic of the zone must be recognized before we can come to a decided conclusion, and final proof will be found in connection with structural, textural, topographic, and other relations discussed below.

This statement that covellite occurs only as a secondary sulphide should be modified on account of its occurrence as a fumarolic mineral in volcanic vents, but as such deposits would not be mistaken for secondary enriched sulphides, this exception is of little importance. Its limited distribution, however, is of little value as a diagnostic mineral, and Kemp[30] considers this scarcity as a proof that reducing conditions obtain in this zone. The interesting feature about the occurrence of covellite is that it forms large ore deposits only in copper veins carrying enargite, and yet not in all enargite veins, for at Butte some of these enargite veins carry extensive covellite ore deposits, while others do not. Lazerovic[31] states that enargite ($Cu_2S.As_2S_5$) forms As_2O_5 on oxidation, and that this strong oxidizing agent causes the precipitation of the cupric sulphide. There was reason to expect that this important subject would be discussed in Weed's report on the Butte district, but unfortunately it was not done.

Chalcocite (and silver-bearing chalcocite, stromyerite, and acanthite) is the great secondary sulphide ore, although it probably occurs as a primary mineral in some localities[32]. It is believed that the 'sooty chalcocite' so common in enriched orebodies is always secondary.

The significant minerals, that is those more often secondary than primary, are given by Ransome as follows: stephanite ($5(Ag_2S)Sb_2S_3$), polybasite ($9(Ag_2S)Sb_2S_3$), argentite (Ag_2S), bornite ($3(Cu_2S)Fe_2S_3$), pyrargyrite ($3(3Ag_2S)Sb_2S_3$), and proustite ($3(Ag_2S)As_2S_3$). Other minerals occurring both as primary and secondary are pyrite (FeS_2), marcasite (FeS_2), chalcopyrite ($Cu_2S.Fe_2S_3$), bornite ($3(Cu_2S)Fe_2S_3$), galena (PbS), blende (ZnS), tetrahedrite ($4(Cu_2S)Sb_2S_3$), and enargite ($Cu_2S.As_2S_5$).

The gangue minerals of this zone are those formed by descending acid solutions, or by alkaline or lime bicarbonate solutions, and are chiefly as follows:

Chalcedony, opal, copper stained chrysoprase, and quartz, kaolin, gypsum, anhydrite (at Bor, East Servia), and fluorite. Calcite is lacking where the solutions are acid.

Gold Production, Federated Malay States

In 1911, 241.8 oz. of gold was exported from Negri Sembilan, 1309.5 oz. from Perak, 7677 oz. from Pahang, making a total of 9228.3 oz., valued at $174,100, as against 16,767 oz., valued at $326,525, in 1910. Severe drought during the first 9 months of 1911, followed by abnormal rains, caused considerable loss in the mining industry. Scarcity of firewood is causing the rapidly increasing use of coal. More activity in prospecting was evident in 1911, while the installation of machinery in mines is being gradually undertaken and opens a large market for this product.

[28] *Liebig's Annalen*, Vol. 249, p. 336, 1888.

[29] This discussion is founded on W. Lindgren's and W. H. Emmons' tables of minerals, and F. L. Ransome's discussion of the criteria of secondary sulphide enrichment. See bibliography at end of second part.

[31] 'Die Enargite-Covellin-Lagerstätte von Cuka-Dulkan bei Bor in Ostserbien,' p. 357, 1912.

[32] It occurs in the Bonanza mine, Alaska (?), the Vergilina district, Virginia, some primary chalcocite at Butte (?), and is reported in a pegmatite dike.

Review of Gold-Dredging in 1912

By Charles Janin

The United States Outside California

The year 1912 was a rather quiet one for gold dredging in the United States outside of California. From what information is available, I have prepared a table to accompany this review, showing the location of 22 dredges that operated or were being constructed during the year. Some of these boats proved unsuccessful and were shut down after a short run—notably those at Kennedy Placers, Montana; Mystic, South Dakota; and on the Chestatee river in Georgia. While the exact figures for the total yardage handled by all the dredges during the year is not available, it can be closely approximated for the purpose of this review at 14,500,000 cu. yd., divided as follows: Montana, 6,000,000; Idaho, 5,000,000; Colorado, 2,500,000; other dredges, 1,000,000, the latter figure probably being in excess of the yardage actually handled. These figures seem small in comparison with the total yardage handled by the California dredges during 1912, which will closely approximate 68,000,000. Details regarding operations in California are given on another page.

DREDGES IN THE UNITED STATES OUTSIDE OF CALIFORNIA

*Idle. †Under construction; will be at work early in 1913. ‡Moved to new ground and will commence operations early in 1913.

Montana.—Details of operations of the dredges at Ruby are not available at this writing. The old dredges of the Conrey Placer M. Co. and Poor Farm Placer Co.,* which have been operated for years, required considerable repairs during 1912. It was also necessary to replace the big screen on No. 4, the 15-ft. dredge which was built during 1911 so the yardage handled fell somewhat short of expectations. The operating costs were also higher than normal. The two companies are under the same management and operate and own dredges. No. 1 dredge has 7½-cu. ft. buckets and handles about 90,000 yd. per month; No. 2 has 9-ft. buckets and averages about 100,000 yd.; No. 3 now has 9-ft. buckets and probably averages about the same yardage as No. 2; No. 4 averages between 225,000 and 250,000 yd. per month.

The Magpie dredge in Lewis and Clark county is reported as doing good work. The dredge of the Kennedy Placers in Missoula county was shut down. Some new areas were being examined in the state during 1912 with a view to building dredges if conditions were found favorable. The results of these investigations are not yet known.

Idaho.—The principal gold dredging operations in Idaho are those of the Boston & Idaho Gold Dredging Co. at Boise Basin. These were described by J. H. Miles in the *Mining and Scientific Press* of September 14. The company operates two dredges, the new 15-ft. boat built by the Yuba Construction Co. has been doing excellent work averaging over 300,000 cu. yd. per month. The ground is about 32 ft. deep and is exceptionally favorable for obtaining high yardage and low operating cost. The 5-ft. Risdon dredge of the same company handled an average of 68,000 yd. per month. The Kirtley Creek dredge is said to be doing good work. This has 9-ft. buckets and is operating near Solomon. The small dredges at Pierce City worked part of the time, the Sprague, a 3¼ Risdon dredge, is said to have had a good season. A new dredge is planned for the Quartz Creek region in this district in 1913 by W. J. Harris and others of Spokane.

Colorado.—Three dredges worked in the Breckenridge district in Summit county during the year. The dredging season averages about eight months, from the latter part of March to the first of December. The cost of dredging at the French Gulch dredge, a 5-ft. Bucyrus boat, is from 5½ to 6c., handling about 70,000 cu. yd. per month. The Colorado

*Described by Hennen Jennings in *Mining and Scientific Press*, January 6, 1912.

Gold Dredging Co. has a 9-ft. Bucyrus dredge and handles about 150,000 yd. per month, the cost of dredging being about 5c. per yd. The Reliance dredge handles about 70,000 yd. per month. The two smaller boats are known to have been making money this season.

Nevada.—The 5-ft. Risdon dredge of the Federal Mines Company, which was shut down after operating for a short time in Spring Valley, Humboldt county, was moved to a new area in the same district and will commence operations early in 1913.

South Dakota.—Castle Creek dredge at Mystic, South Dakota, which was built by the Stearns-Roger Manufacturing Co., during 1911, for Denver men, has been shut down. The ground did not contain sufficient gold to make the project a financial success.

Wyoming.—The Shoshoni Gold Dredging Co. is operating a 3½-ft. Marion dredge near Shoshoni, Wyoming. No information is given out by the management concerning operations.

Oregon.—The only dredge operating in Oregon is the Champlin boat on Foote creek, Jackson county. This dredge was sunk in December 1911, but was raised and again put in commission. The Powder River dredge near Sumpter is fast nearing completion and will commence operations in January 1913. This is a 9-ft. boat built by the Yuba Construction Company.

Georgia.—The 3-ft. Bucyrus dredge of the Sewell Dredging Co. was shut down during the year. The ground did not contain sufficient gold to pay operating expenses.

Alaska

†The total gold production from dredge operations on the Seward Peninsula for 1912 will approximate $1,250,000. There were in operation or under construction a total of 39 dredges. A number of these had a successful season, though as pointed out in my previous article, some of the boats operated at a loss. The Wild Goose dredge on Ophir, which averaged 2300 yd. per day for the last 40 days and about 2000 yd. per day for the entire season, had a successful year. The Blue Goose, working part of the time on leased ground and part on claims owned by the company, is reported to have made a large clean-up. This dredge averaged about 1000 yd. per day and will be somewhat remodeled during 1913. A new bucket line of 60, 3-cu. ft. close-connected buckets is being designed by the Union Construction Co. to replace the old line of 5-ft. open-connected buckets which actually only held 4 cu. ft. The old tumblers will be used; additional power will be supplied, probably by a gas-engine using distillate to supplement the wood-burning steam plant, though the management may decide to remodel the entire present plant. With the contemplated improvements an increased yardage will be obtained in 1913.

Among the boats built during 1912 the Kimball & Saupe dredge built for C. Flodin at Eastfork on the Solomon river had a good run. The returns from Shovel Creek dredge built by the Yuba Construction Co. for Newton Cleaveland and others and operated by Cory C. Brayton were also encouraging. This dredge has 2½-ft. buckets and averaged about 1000 yd. per day. The fuel used was about 240 gal. of distillate per 24 hours, costing 25c. per gallon at the dredge. The Ruby dredge built by the Union Construction Co. and in charge of William Colley had a successful run of sixty days averaging 87% running time and handling 65,000 yd. while dredging to a depth of from 5½ to 14 ft. This dredge is equipped with 2¾-ft. buckets. The consumption of distillate was 132 gal. per day with a 90-hp. engine. The Johnson dredge, built by the Union Construction Co., gave some trouble when first started, but afterward did good work. The 3-ft. Inmachuck dredge erected by the same company, handled over 65,000 yd. in 50 days, digging to a depth of from 9 to 12 ft. This dredge is equipped with two 50-hp. Union gas-engines and used 210 gal. of distillate per day. The cost of oil was about 40c. per gal. at the dredge, but this it is expected will be reduced to 30c. by taking advantage of winter hauling and utilizing present drums.

The little 1¾-ft. Ernst dredge on the Nome beach, is reported to have cleaned up $20,000 for the season. As this dredge did not start until the latter part of July, the owners are naturally pleased with the results which may encourage further attempts at beach dredging. This is a Barnard dredge, but was put together by William Colley of the Union Construction Co. The Kelliher dredge, built by the Union Iron Works in 1912, operated successfully. Some of the ground had to be thawed, as it was solidly frozen. The Nome Exploration Co. boats, better known as the Powell dredges, operated part of the season. It is stated that the Wonder dredge made a good recovery, but not sufficient to make any material change in the financial standing of the company at Nome. Construction work was continued on the new 9-ft. boat on Flat creek and this dredge will be finished in 1913. Work was commenced on the hull of the Greenberg or Holyoke dredge before the last steamer left Nome. This work will be continued during the winter and the machinery for the dredge will be taken in on one of the first boats in the spring of 1913. The oil-burning system which was tried on the Three Friends dredge in the summer of 1912 did not give the results the management anticipated, very little saving being effected over the use of coal. Some days as high as 60 barrels of oil were consumed. It is possible that the stockholders of this company may at least realize that the steam plant, which might be a credit to Noah's Ark, but hardly to the management of a modern dredge, should be replaced by an up-to-date plant. The operating cost of this dredge was probably the highest on the peninsula for 1912.

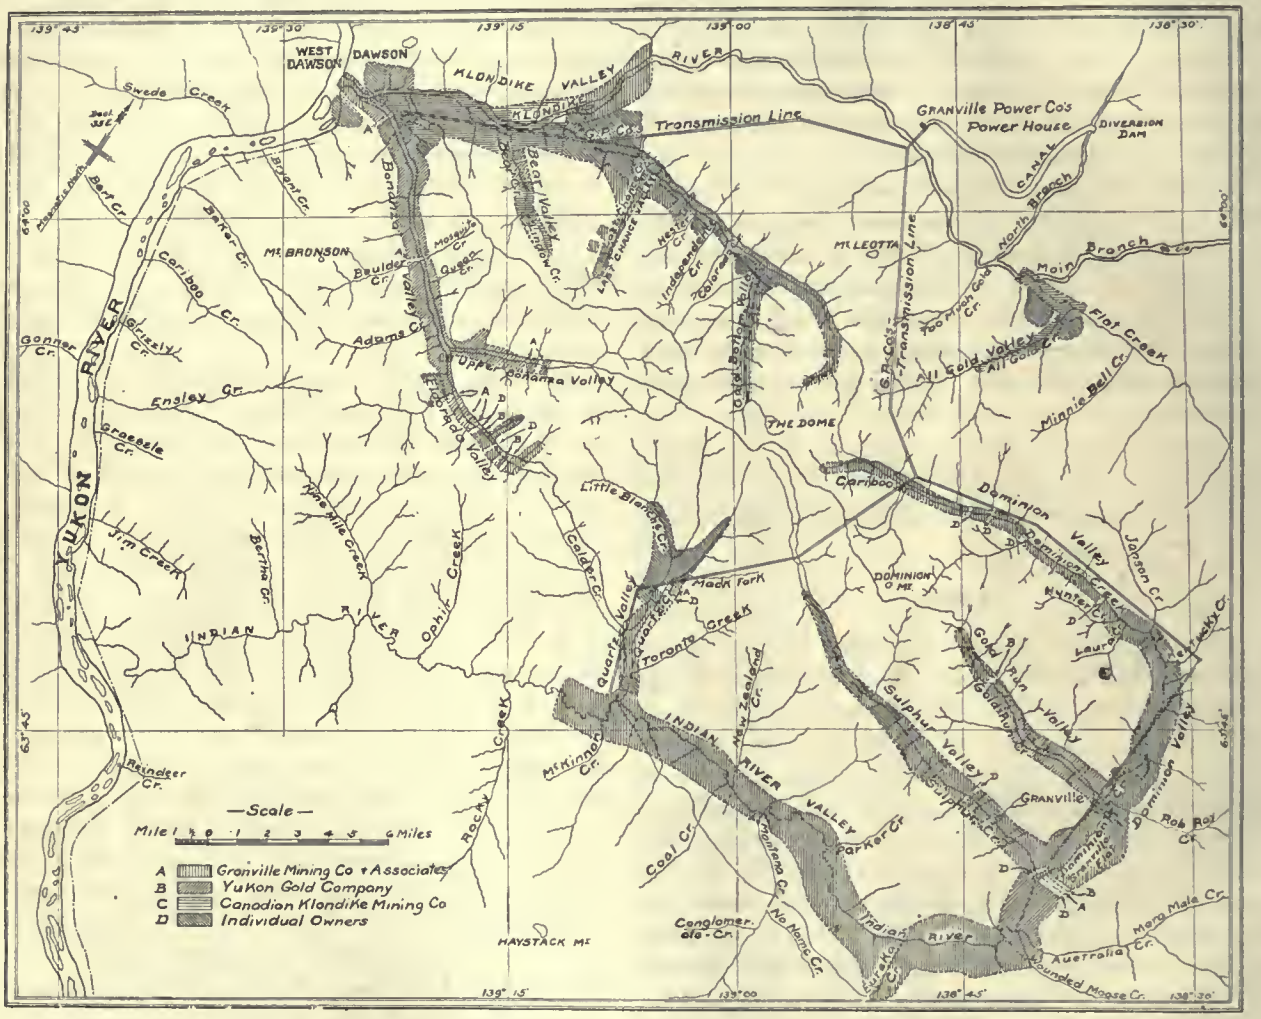
In addition to the dredge mentioned in my previous article, there are several dredges proposed for 1913. E. C. Julian is figuring on a new boat for St. Michael's creek below his present dredge. It is stated that the Osborne dredge will be remodeled;

†The progress of gold dredging on the Seward Peninsula was discussed in the *Mining and Scientific Press* of September 28, and to that article the reader is referred for a general discussion of the season's work. Here is given a very brief summary of operations since Mr. Janin's departure from Nome.

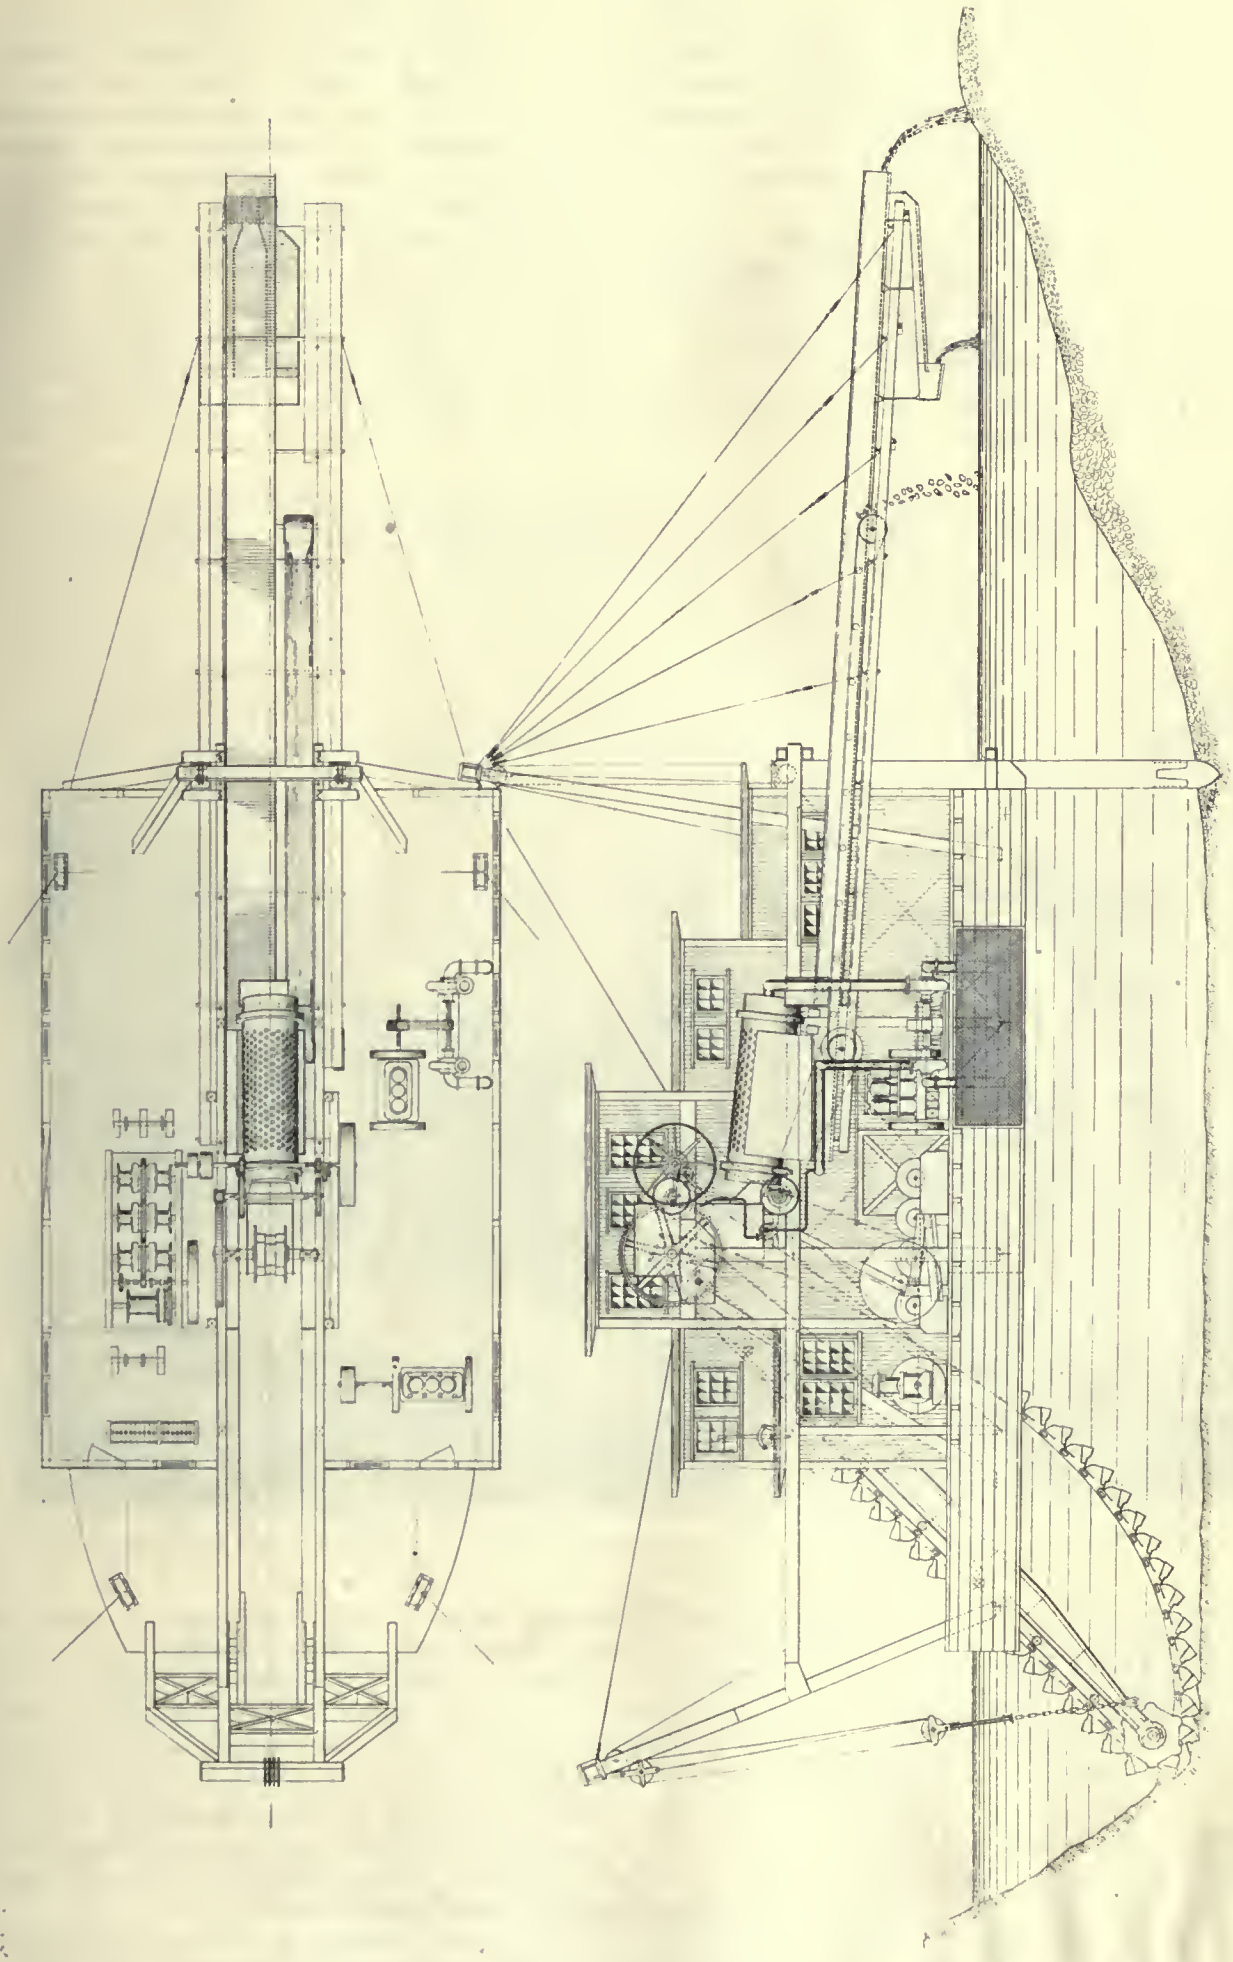
the hull thoroughly overhauled and the old engines and steam plant, which have caused so much delay and expense, replaced by gas-engines. The present system of gold saving tables will be taken out and replaced by a short screen with 2½-in. perforations for coarse rocks. The under size from this screen will pass to a flume 42 in. wide, extending about 40 ft. behind the dredge. A short stacker will extend about 25 ft. outboard and drop the coarse rocks inside the line of tailing from the flume. The Middaugh dredge on Saunders creek, which was idle during 1912, has been dismantled and the machinery will be hauled over the snow to ground near the junction of Hobson creek with Nome river, where a new hull will be built in the spring. The Union Construction Co. has charge of this work. There are several other dredges planned for the coming season. The flume type of dredge, of which a drawing is shown, has proved satisfactory in Alaska, and there seems to be a good future for boats of this type. These boats have a small initial cost and a low operating and repair cost. Some are built without the screen shown in the drawing, the buckets dumping directly into the flume. The Kimball and Saupe dredges on Shover, Eastfork, and Ophir creeks are of this type. These boats do good work where there is not much clay. It is found, however, that the addition of the screen with 2½ or 3-in. perforations assists greatly in washing the gravel, and the dredge is more adaptable for all classes of ground. As pointed out in my previous article, there is a good future for small dredges in Alaska, and there is much competition between different dredge construction companies to secure this trade. The Yuba and Bucyrus companies had an engineer, C. T. Nicholson, investigating the needs of that territory during the past year, and are now figuring on several new boats which may be built in 1913. The Union Construction Co. has booked orders for several boats for 1913. The other companies have not yet reported.

Yukon Territory

The Klondike goldfield extends southeast from Dawson. The best known and most productive parts of it cover a parallelogram of about 50 miles long by 20 wide. The accompanying map shows the known workable areas of the Klondike goldfield as figured by the engineers of the Granville company, and the division of the field with regard to ownership. The first large company in the district was the Yukon Gold Co., which owns extensive areas on Bonanza and Hunker creeks and has a capitalization of $17,500,000. This company began equipping its properties in 1906 and at the present time has 9 dredges in operation in addition to hydraulic plants. The dredges of the Yukon Gold Co. handled for the season of 1911 a total of 4,151,249 cu. yd., having an average value recovered of 64.35c., and an operating cost of 35.43c. per cu. yd. Seven of the



THE KLONDIKE GOLDFIELDS.



NEW TYPE OF DREDGE FOR ALASKA; DESIGNED AND BUILT BY THE UNION CONSTRUCTION COMPANY.

dredges averaged 171½ days as compared to 159 days for 1910. Figures for the total season of 1912 are not yet available but up to September 30 the dredges handled 4,408,300 cu. yd. with an average recovery of 66c. per yd. It is said that the operating cost was reduced to about 30c. per yd. The total yardage for the season will be somewhat in excess of 5,000,000. The following summary of dredging results will be of interest:

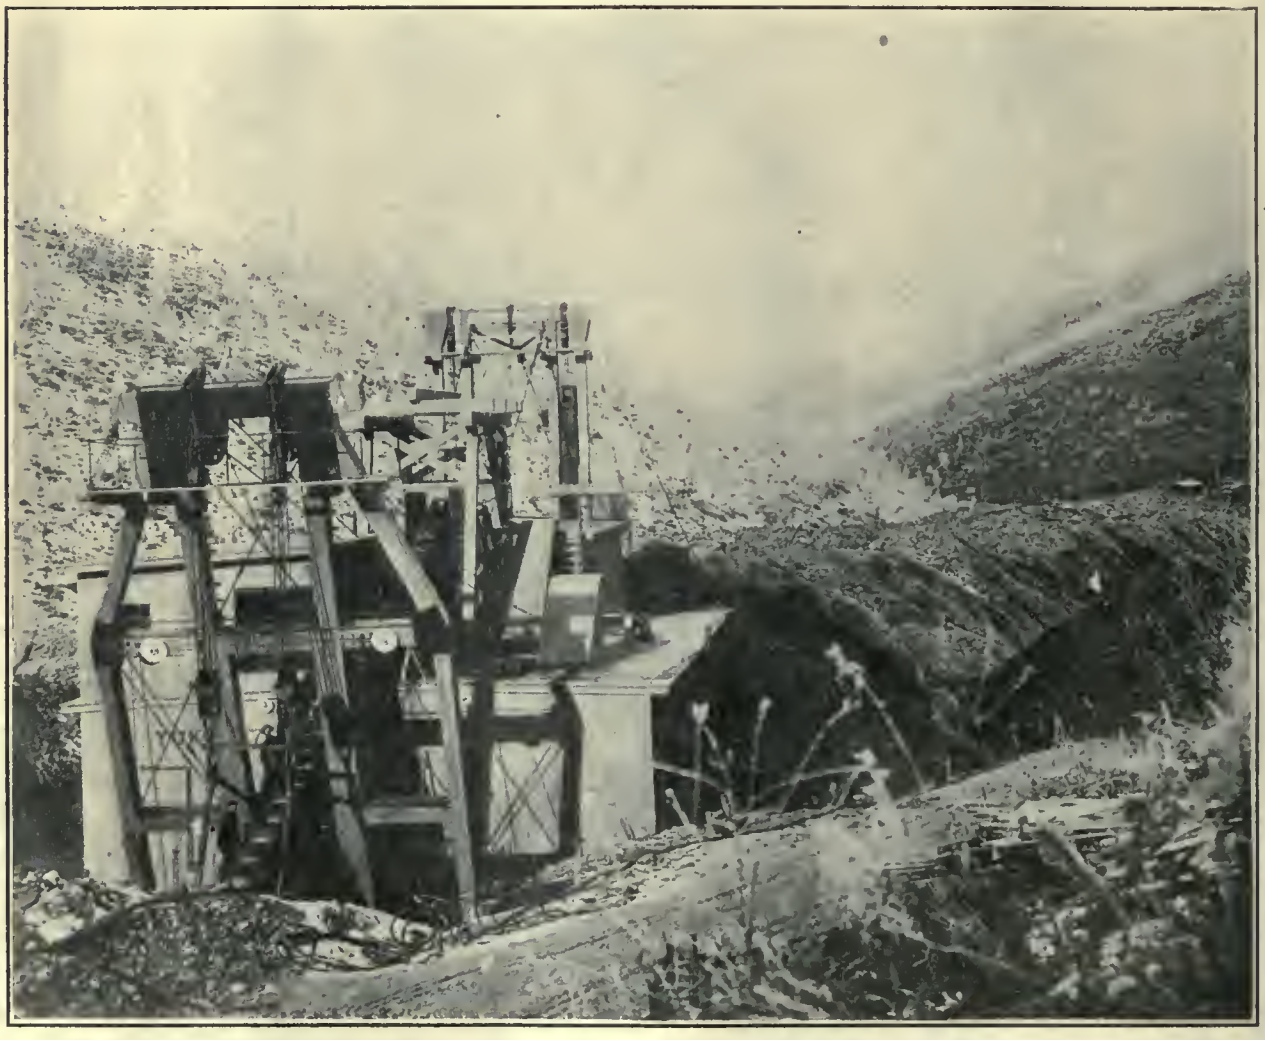
Year.	1909.	1910.	1911.	1912.
Cu. yd. handled	2,381,880	3,249,788	4,151,249	*4,408,300
Recovery total	$1,363,722	$2,150,723	2,671,845	$2,917,700
Per yard, cents	57.24	66.18	64.35	66.
Cost, cents	31.91	31.09	35.43	†30.
Operating season, days	132½	159	171½	

*To September 30 only, about 5,200,000 yd. for season.
†Approximation.

There are 8 dredges now on the property, two of 5-ft. and six of 7½-ft. capacity. Dredges No. 8 and 9, 7½-ft. Bucyrus boats, are equipped with steel hulls and frames, but the housing is of timber. The ground average 4 to 20 ft. deep. Dredge No. 1 was moved last year to Flat creek, Iditarod, where a successful season in 1912 is reported. Most of the ground so far worked at Iditarod has proved rich.

The Granville Co. has consolidated a number of properties. It was promoted by H. C. Hoover, A. C. Beatty, and A. N. C. Treadgold in 1912, and has a capitalization of £2,500,000, of which £1,000,000 is in convertible 6% debentures. The Granville company controls a large area as shown on the map. It is under the management of H. C. Hoover, A. C. Beatty, H. H. Webb, and others. Mr. Treadgold is managing director. The engineers first estimated that in addition to large areas of lower grade gravel there was a total of 300,000,000 cu. yd. that would average 30c. per yd., which could be treated at 12c. per yd. On account of the low operating cost obtained by Boyle dredge, it is now claimed that the cost can be reduced to 8c. or less per cubic yard. The company owns the Granville Power Co. which has a hydro-electric plant of 6000 kw. capacity and is capable of further increase to 10,000 kw. when needed. The Granville company has entered into a long term contract with the Yukon Gold Co. under which the latter agrees to pay a minimum of $85,000 annually for power. The power produced in excess of the amount sold the Yukon company will be divided equally between the Granville and the Canadian Klondyke companies. The Granville company has provided funds for two additional dredges for the latter company which will be in operation in 1913. The Granville will receive a substantial income from its holdings in the Canadian Klondyke Co., in which it owns $1,500,000 in 6% debentures and 29% of the shares. The debentures can be converted into 20% of the share capital of Canadian Klondyke Co., and it is likely that this will be done.

The Canadian Klondyke Co. has two dredges in operation. According to the report of J. W. Boyle dated April 26, 1912, these have handled a total of



YUKON GOLD CO. DREDGE No. 7, BUILT BY MARION STEAM SHOVEL CO.; ILLUSTRATING CHARACTER OF GROUND WORKED AT DAWSON.

5,346,956 cu. yd., with a gross recovery of $1,434,321.82 or an average of 26.93c. per yd. In regard to working costs Mr. Boyle says that by stripping the ground and using heating appliances for the protection of the machinery during the excessive cold weather, it proved possible to lengthen the operating season and reduce the cost of No. 1 dredge, which has 7½-cu. ft. buckets, from 23.2c. per yard for 1905 to 11.3c. in 1911. The No. 2 dredge, with 16-ft. buckets, operated for 5.98c. per yard. These figures are exclusive of overhead and general charges, which approximate 1c. per yard additional. The Marion Steam Shovel Co. is building two additional 16-ft. boats for the Canadian Klondyke Co., and it is claimed that the four boats will be able to handle 7,000,000 cu. yd. annually, at a cost of 6c. per cubic yard. For the purpose of determining the value of the valley property, 830 holes have been sunk between the mouth of Bear creek and the mouth of Bonanza creek and from the results obtained the management claims in excess of 100,000,000 yd. of gravel that will yield an average of 22c. per cubic yard. While exact figures are not at present available, it was expected that during 1912 a total of 3,000,000 yd. would be dredged, with a profit of approximately $450,000. The profit during 1911 was about one-half this amount.

In addition to these companies there is a small Allis-Chalmers dredge of about 1000 cu. yd. daily capacity in operation on the Canadian Forty Mile creek and a small Risdon boat on the American Forty Mile.

Changes in the Bituminous Coal Industry in 1912

By George H. Cushing

It does not require much penetration to see that a process of solidification is going on rapidly in the bituminous coal trade. Such progress has been entirely obvious. The report of the United States Bureau of Census, covering the data for 1909, and published within the year, was to the effect that something like 45% of the mine owners of bituminous coal mines are engaged in manual labor in and about their mines. This, of course, referred to the number of shafts rather than to the percentage of output, but nevertheless it portrayed a primitive condition. It meant very many small mines competing for distant and local tonnage, producing according to crude ideas, and selling without regard for an exact accountancy. It meant strict obedience to the law commanding competition and it meant disorganization of the industry in its most striking form.

Since the data upon which the Bureau of Census based its report were collected, the members of the coal trade have recognized both the extent and the effect of this disorganization and have tried to correct it. This was on the theory that disorganization once recognized is speedily ended. The known avenues of escape from this condition were only two: The removal of certain mines and mining companies from the commerical markets as the result of integration of business; and the physical amalgamation of companies to reduce the number of those who were appealing for small orders from small buyers. Both of these avenues have been followed and the result, at the conclusion of that year, is really astounding when measured alongside the remarkable exhibit made by the Bureau of Census.

Two striking examples will suffice to show the tendency of big business to become a factor in the production of bituminous coal. Within the last year there has been an ominous change—this viewed from the standpoint of steam users—in the market value of coal in what might be called the western region. Three years ago the contract price on Illinois screenings, for example, was from 45 to 57½c. per ton, while the maximum price in summer was 75 to 85c., and the minimum price in winter was from 20 to 30c. The year following, contract prices rose from 57½ to 60c.; the minimum price in summer was a little higher and the minimum price in winter was not quite so low. This year the contract price on Illinois screenings ranged from 75 to 90c. per ton at the mine, and it is peculiar that the winter price is actually higher than was the summer price, the spot market being quoted all the way from 75c. to $1 per ton. There is now little difference between the price of fine coal and the price of mine run, a result traceable directly to the increasing use of various kinds of stokers in power plants.

The larger consumers of coal had previously made the unequivocal statement that when the time came that they must pay more than the cost of production for their steam coal, and especially for their small coal, they would begin to mine their own coal. The rise in market prices has warned these large companies that the time is approaching when they must pay more than the cost of production for their fuel, and this has directed attention specifically and pointedly to the need of coal-land reserves. It is peculiar and perhaps significant that this need for coal-land reserves should appear, at the psychological moment when the operating bituminous coal companies, worn out by the struggle of years to make money, discouraged and all but bankrupt, should be seeking a purchaser upon whom to unload their properties. To the outside observer it seems, that they, the coal men, lost their courage just at the moment when the long and hard fight was about won. However that may be, the operators' designs to sell, and the big corporations' desire to buy, have led to consummation of unusually large land transactions within the last year.

By way of example, J. K. Dering and R. R. Hammond brought complete deals by which control of the major part of the coal land of Montgomery county, Illinois, passed into the hands of interests allied with the Chicago & Eastern Illinois railroad. These lands were subsequently leased to F. S. Pea-

body, who embraces them in a large organization for the production and sale of coal in Chicago. Macoupin county, Illinois, is considered one of the important coal reserves of that state, and control of its coal lands was solidified and consolidated last year even beyond that which followed the entry of such live buyers as the St. Paul and Northwestern railroads. The Steel Corporations has about completed its purchases of Franklin county coal lands, and now owns in the neighborhood of 82,000 acres. Interests allied with the St. Paul railroad have purchased in that same field 16,000 acres, while the Rock Island, the Missouri Pacific, and the Illinois Central are also represented in that county. In addition to these reserves, a movement is now seriously under consideration for the consolidation of the strictly commercial mines in that district.

As this is written, negotiations are well advanced for the sale of some 36 mines in the Springfield district of Illinois to F. S. Peabody, who intends to consolidate them into one organization. A movement of similar importance and scope is under consideration for the inner group around St. Louis, but the negotiations there are not near so advanced as in the case of the Springfield district. It must be apparent that with the operators consolidating among themselves, and with large interests buying into the fields, the solidification of Illinois coal lands control is progressing rapidly. Particular point is given to this assertion by the fact that the large interests alone today hold five hundred thousand acres of Illinois coal lands.

It would be possible to show practically the same tendeney now prevalent in other fields, but a mere recital of further details would give no clearer idea of the drift than is shown by Illinois. The two important facts are, that big consumers are beginning to realize the need for coal reserves and are satisfying it, while the operators are beginning to realize the need for some kind of coal control and are beginning to bring it about. Powerful forces are at work in the bituminous coal trade, and candidly the drift is toward that consolidation that has been seen in other lines of industry, and obtains in a rather exaggerated form in the anthracite field. It seems now only a matter of time—and perhaps a very short time—until the nation will have to confront an entirely new situation as to fuel. Wise heads are anticipating this time, and are trying now to bring about a change in public sentiment which will permit this reorganization under public supervision.

This change in another way, but one equally significant, is seen in the operations of of the Consolidation Coal Co. in the East. That concern with its feet firmly planted in Maryland, in central Pennsylvania, and West Virginia, has within the last year extended its operations on a large scale to the fields of Kentucky. Concerning this latter development there has been a great deal of thoughtless discussion. It must be evident that the Consolidation Coal Co. would not spend millions of dollars in development, other millions of dollars in making railroad connections to a new mining field, and vast sums of the exploitation of a new coal if it did not have a need for that particular kind of fuel or a need for a coal nearer another market which it wanted to reach than the mines previously owned. Particular emphasis is placed upon this fact by the statement that in the Fairmont field alone one of its bases of older operations, that company has a virgin coal reserve sufficient to last it for 150 to 200 years. It has a virgin coal reserve in central Pennsylvania of almost equal proportions and its Maryland field is not by any means worked out. As a consequence, it is not going into Kentucky as a substitute for operations in other fields, but for complementary development. This calls attention to the new idea now becoming prevalent among the larger companies, which is to have coal that makes a wide appeal to the market, coals to fit into particular and peculiar uses, and especially coals virtually on the threshold of each market. The entry of the Consolidation Coal Co. into Kentucky is a definite move in all of these directions; therefore the action of the Consolidation Coal Co. is significant of trade drift and is not the mere expansion of a single company. It also points to the fact, which is the foundation of this article, that the bituminous coal industry is beginning to adopt something approaching sane merchandising methods. This might be expected to come along with the solidification of the industry.

As showing that the same tendeney is reaching into the minutae of the industry, brief attention may be made of new methods in distribution or in retailing. this only, however, to show the drift. The consolidation of retail yards in Chicago took place several years since. Within this last year, two of the largest retail concerns in New York City have consolidated, giving the new company a really commanding position and a central organization with diversified and far flung points of distribution. Within the last year, eleven companies in Philadelphia have consolidated into the Geo. B. Newton Coal Co., with a central administrative organization and widely diversified points of distribution. Thus, even the retail trade is being brought under central control. This is perhaps the older and cruder form of organization, but things of that kind may be expected to happen till the public changes its attitude.

A more significant and a newer form was that adopted by the retail dealers of Rock Island, Illinois. The identity of individual plants was maintained as also that of individual selling organizations, but the several companies united in the construction of a central coal elevator. This provides compartments, one for each of the companies interested, and these compartments are divided into separate bins for the storing and automatic loading of different grades of coal. Along with this pooling of yard space there has come, as a natural sequence, the pooling of delivery facilities, and thus the reduction in expense, and hence the vast improvement in the service which may be given the public.

As these things will indicate the bituminous coal industry is coming to be a vastly different thing from what it was five years ago, and the impression which one gains from a study of these conditions is that the transformation, rather than being complete, is just beginning.

Progress of Copper Metallurgy

By Thomas T. Read

The past year has been one of high prices for copper, compared with those immediately preceding, and therefore shows a correspondingly rapid rate of metallurgical progress since the greater profit obtained per pound of copper produced is a stimulus to secure better recovery and greater output, while from the greatly increased operating profits considerable sums may be allocated for new construction and experimental work without marked effect upon dividend disbursement. But progress has consisted largely in departures from ordinary practice rather than in improvements in accepted methods. The most significant events of the year are the adoption of the Minerals Separation Co. flotation process at the Braden mine, in Chile, and the sudden adoption of the Great Falls type of converter in a number of the large smelting works, including several of the American Smelting & Refining Co. plants. Almost equally significant is the large amount of work which is being done in leaching methods for the extraction of copper, though definite results are meagre as yet. Throughout the whole metallurgical field, however, encouraging progress has been exhibited, as will be seen from the more detailed discussion of each topic below.

Smelter Fume

There has been little of new development in regard to the smelter-fume situation during the year. The committee appointed to consider the situation at Anaconda has made no report as yet, as experimental work by the Bureau of Mines, under the direction of F. G. Cottrell, is still in progress both at Anaconda and at the laboratory of the Bureau in San Francisco. Experimental work with the Thiogen process[1] is still in progress at Campo Seco, and an account of the results attained has been given by F. L. Wilson[2]. Mechanical difficulties, some of which were not incident to the process itself, have greatly interfered with its operation on a working scale. During the year a test of the Kelly process was made at Los Angeles by officials of the Bureau of Mines, which proved it to be of no practical value as far as smelter fume is concerned. The smelters in Shasta county, California, remain closed with the exception of the Mammoth plant of the U. S. S. R. & M. Co., which continues to operate its baghouse with satisfactory results. At the end of the year tests with the Heslewood process were in progress at the electric smelter at Heroult, but no results have been disclosed.

New Construction

An unusually large amount of new construction has been started during 1912. The Granby Consolidated Mining, Smelting & Power Co., Ltd., is planning the construction of a new plant on Observatory inlet, in the northern part of British Columbia, to smelt the ore of the Hidden Creek mines, which that company took over in 1911. It is generally understood that a blast-furnace and a converter are to be constructed, and it is reported that bids for a 2000-ton plant have been called for. The ore is high in sulphur and the blast-furnaces will be able to operate with a minimum percentage of fuel on the charge. The company states that 5,000,000 tons of ore averaging 2.2% copper and about $1 in combined gold and silver has been developed. About $200,000 has been spent on the property and it is estimated that equipment will cost $1,600,000. Actual smelter construction will probably be started in the early spring. At the present plant of the company, at Grand Forks, B. C., the only change of note during the year was the construction of a second unit in the slag conveying system. This is briefly described by G. M. Lee.[3] The slag from the settlers is granulated in water and flows through launders lined with steel channels to receiving bins which dewater the slag before delivering it to two 24-in. belts which convey it up an incline of 18 degrees to a point 115 ft. above the present dump level. Two belts, one running to the left and the other to the right, are used in order that one may always be in operation in case of accident to the other. As might be expected, the sharp particles of slag give much trouble from wear in the launders and on the belt, and it would be interesting to try hard steel plates in the launders, as has been done by the Quesnelle Hydraulic G. M. Co., for lining sluices in hydraulic work, with excellent results. The smelters at Trail and Greenwood have made few changes.

At Tacoma the copper smelting plant of the American Smelters Securities Co. is undergoing complete reconstruction. This plant chiefly smelted lead ores until recently, when the growth of the lead smelting industry in Utah and the increased production of copper ores in Alaska have made such extensive changes in the work at Tacoma necessary that it was judged best to entirely rebuild the plant. Since most of the ore at this plant arrives by steamer, unloading and storage facilities are an important feature of the plant construction. New blast-furnaces, 42 by 260 inches, are under construction, and accessory apparatus as required. The electrolytic refinery at this plant, the only one in operation west of the Rocky Mountains, is being increased in size from 24,000,000 lb. per year to 36,000,000 lb. per year capacity. W. H. Howard is in charge of the work of reconstruction. No changes of note have been made at the three smelters in operation in California; the experimental work in progress at Campo Seco is mentioned elsewhere. In Nevada a new smelter, that of the Mason Valley Mines Co. has been blown in. A full account of this appeared[4] in these columns. The

[1] *Mining and Scientific Press*, Sept. 23, 1911, p. 386.
[2] *Mining and Scientific Press*, April 6, 1912, p. 497.

[4] *Mining and Scientific Press*, August 31, 1912, p. 267.

interesting changes in practice made at the Steptoe Valley plant are elsewhere described by S. S. Sorensen.

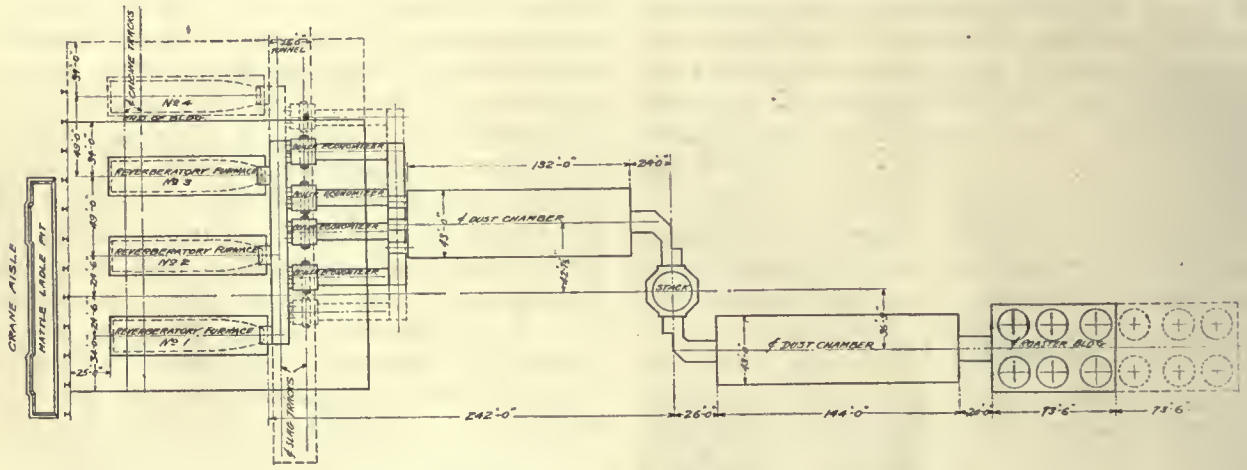
At the Great Falls plant of the Anaconda C. M. Co. in Montana, extensive re-construction is under way. The gas producers and gas-fired reverberatory furnaces now in use will be torn down and replaced by coal-fired reverberatory furnaces with a specially designed firebox, something like a gas producer. The remarkable work done at this plant with the giant basic-lined converters and the changes at the other plants in Montana are elsewhere noted.

The most important new smelter constructed during the year is the American Smelting & Refining Co. plant at Hayden, Gila county, Arizona. The preliminary work on this plant was done by the Ray Consolidated Copper Co., but it was later taken over and completed by the A. S. & R. Co. as a customs smelting plant. In keeping with the general policy of this company, no description of its construction or operation has yet appeared. The new Pioneer smelter is referred to later. The Swansea smelter[5] was blown in during the autumn.

A good deal of reconstruction work is in progress in Arizona and New Mexico. The entire plant of the Arizona Copper Co. at Clifton, is under reconstruction, under the direction of L. D. Ricketts, grading for the new site having begun in April. The new plant will follow the general plan of that at Cananea, the design including three 8-ft. converters of the Great Falls type, air-cooled roasters of the Herreshoff type, and a 300-ft. stack, 22 ft. diameter. The Calumet & Arizona has made extensive changes at its plant, including the construction of five converters of the Great Falls type. Construction work at both these plants is under the immediate supervision of Repath & McGregor. It is hoped that a full description of these will be available for publication later in the year, so no further comment is made here. Some new construction has been completed at nearly every plant, but to give details would require too much space and the data concerning the Copper Queen which follows must suffice.

The following details as to new construction at the Copper Queen smelting plant have, through the courtesy of Dr. James Douglas, been kindly furnished by Frank Rutherford, superintendent. The main changes and improvements at the Douglas Reduction Works of the Copper Queen Consolidated Mining Co. during 1912, were the finishing and starting up of the reverberatory furnace plant, the adopting of the basic lining for converters and the installation of two stands of upright converters of the Great Falls type. The reverberatory plant consists of two furnaces with 90 by 19-ft. hearths, designed to use oil as fuel, with two 520-hp. boilers placed in parallel back of each furnace. To one set of boilers, only, were added Sturtevant economizers with the idea of finding out, by practical operation, whether there was any advantage in their use. To date, on account of reasons beyond control, it has not been possible to run the two furnaces sufficiently long to give conclusive results as to economizers, but it is hoped soon to be able to do so.

Contrary to general practice, a large dust-chamber of 1200 cu. ft. cross-section and 132 ft. long, was built to catch any dust from the reverberatory furnaces that might pass the boilers.



PLAN OF REVERBERATORY AND ROASTING PLANT, COPPER QUEEN.

That dust does pass through the boilers is evident, but the plant has not been running long enough to definitely state whether the amount and metal content is sufficient to warrant the building of a dust-chamber. In the dust-chamber are suspended some 30,000 wires. The roaster plant consists of six 18-ft., 6-hearth McDougall furnaces of the usual type, to which the concentrate is delivered by means of conveyor-belts and a cup elevator. Nothing unusual, or different from general practice, was used in this department. A large dust-chamber was also built to catch the dust from the roasters, similar in design, but slightly larger than the one for the reverberatory furnaces. The gases from both departments go to a common stack 300 ft. high by 22 ft. internal diameter, built of hollow radial tile.

The new converters are of the Great Falls type, 12 ft. in diameter by 12 ft. 3 in. high, and have the top made so that the flame shoots straight up, and not back at an angle, as is the usual practice. The shells are lined with magnesite brick, and work so satisfactorily that four more units are being installed as quickly as possible to take the place of the old barrel type. During the year the management gradually worked out of the acid and into the basic lining for

[5] *Mining and Scientific Press*, December 21, 1912, p. 799.

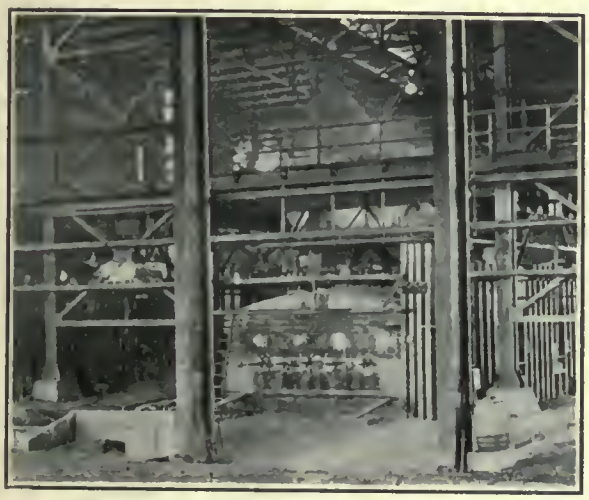
the converters, the Douglas plant now running entirely on the latter.

Reverberatory Practice

In reverberatory practice the change of most interest is the intimation that the use of gas-producers will probably be abandoned in the new construction of the Great Falls plant of the Anaconda Copper Mining Co. The coal used in the producers at this plant is from Belt, Montana, containing 25% ash. The reverberatory furnaces are small, with hearths 15 by 42 ft. and are fitted with checker-work regenerators of the usual Siemens type. Even with great care in dropping charges it was impossible to prevent the entrance of dust into the checker-work, necessitating delay and expense for cleaning at intervals. In the new construction a specially-designed firebox will be used, and waste-heat boilers substituted for checker-work as a means toward heat economy. As this is the only copper smelter in America, to my knowledge, at which regenerative furnaces have been tried, the decision to abandon them is significant. At Kyshtim, in Russia, producer gas made from wood is used for firing 15 by 35-ft. reverberatory furnaces, and in the most important paper on reverberatory smelting practice which appeared during the year, E. P. Mathewson[6] presented before the eighth International Congress of Applied Chemistry a statement of the low cost of smelting there attained by this means. In a run of about six months 10,690 tons of charge was smelted with a consumption of 3417 cords of wood, costing $1.05 per cord at the producer, corresponding to a fuel cost of 33.6c. per ton of charge smelted. The tabular summary of present reverberatory practice in America given by Mr. Mathewson[6] covers the subject thoroughly. D. H. Browne has described[7] the new reverberatory furnaces constructed at Copper Cliff. These are 19 by 112-ft. hearth area and are designed to burn pulverized coal, following the experiments made at the Highland Boy by S. S. Sorensen and at Cananea by Charles Shelby. For full details reference should be made to the original paper. The character of the coal used is not stated, but it is crushed to ¼ in., dried, and pulverized by Raymond impact pulverizers so that most of it will pass a 200-mesh screen. The powder is sucked by fans to a separator at the top of the building, whence screw conveyors take it to the storage bins at the ends of the furnaces. Five 4-in. variable-speed screw conveyors drop the coal in front of air-jets in the burners. The system works well and no difficulty is experienced from the ash, which gave trouble both at the Highland Boy and at Cananea. No attempt is made to save the waste heat in the escaping gases. The new reverberatories at Douglas have already been mentioned.

Handling Flue-Dust and Fine Ore

Interesting progress in handling of flue-dust has been made at the East Butte and Mason Valley smelters. At the East Butte the flue-dust is caught in a dust-chamber constructed from slag by pouring in molds. The chamber is 48 by 70 by 250 ft. in size, with walls 10 ft. thick at the bottom and 6 ft. thick at the top, and is provided with three tunnels beneath for drawing off the dust, the roof being suspended from trusses. The whole was constructed at a cost of $25,000, which must be a record minimum, under the direction of Oscar Rohn, the superintendent. The coarser dust from the end of the chamber nearest the furnaces contains enough coke-dust so that when fed to an ordinary Dwight-Lloyd sintering machine and ignited in the ordinary way a good grade of sinter is obtained. The finer dust, amounting to about one-fourth of the total, requires the admixture of a little ground coke to furnish heat enough to produce a firm sinter. Similar practice at the Mason Valley smelter has already been described[8] at some length in these columns. In a very interesting paper,[8] M. J. Elsing has described the methods of handling furnace charges of concentrate at Cananea. H. Foster Bain has described[9] the machine developed by K. Nakamura at the Shisaka smelter, in Japan, for nodulizing fine ore and also an interesting modification of the Huntington-Heberlein pot for sintering fine ore. The work at this plant is of unusual interest, since peculiar conditions have to be met.



REVERBERATORY FURNACES, COPPER QUEEN.

Converter Practice

The most marked changes are to be observed in converter practice. The use of acid lining for converters is now generally discontinued, except in a few plants where, owing to special conditions, no economy would result from the change. As a natural, though not generally foreseen, result the horizontal cylinder type of converter is now being discarded and the vertical cylinder substituted. As will at once be seen, the vertical cylinder is a much stronger shape mechanically than a horizontal one, since in the one case the open end serves for the addition of matte and the escape of gases, while openings must be made in the side of the horizontal cylinder, thus greatly reducing the strength of the lining. In the case of the acid lining, which required frequent replacement, this facilitated the removal of the old lining without markedly further decreasing the short life of a new one. But when, as at Great Falls, a single basic lining suffices for over two years' continuous operation (in several cases a single lining having lasted through the production of over 12,000 tons of blister), it is essential to make the lining as strong mechanically as possible, since failure results from mechanical strains, and not through chemical corrosion. This factor is of so much importance that this type of converter is now being employed in the plants of the American Smelting & Refining Co., which owns the patents on the Pierce-Smith converter. The central opening also greatly facilitates distribution of material added. The converters at the Copper Queen have already been referred to, and, in addition, the Great Falls type is being used at Cananea, Hayden, and El Paso, for the new construction at the Calumet & Arizona and the Arizona Copper Co., are already in use at Kyshtim, and will probably be employed in the new Granby plant and at Tacoma. At Great Falls it is found that the first essential in use is to secure a proper coating on the basic lining by careful blowing of the first charge, after which manipulation is easy. The success of the 12-ft. converters led the Great Falls management to undertake the construction of a larger size, and a 20-ft. converter was built and blown in during the summer, with remarkably good results. Through the courtesy of C. W. Goodale, A. E. Wheeler, and M. W. Krejci, I am enabled to give the following summary of a run with this converter:

Diameter of converter, inside shell, ft.	20
Diameter of converter, inside lining, ft.	15½
Magnesite brick lining, 2½ ft. on tuyere side, 2 ft. on front tuyeres: 62 of 1¾-in. diam.	
Air, cubic feet per minute	25,000
Air pressure, pounds	6 to 12
Initial charge of matte, tons	65

	Hr.	Min.
Total elapsed time	7	23
Blow on slag	3	35
Blow on finish	1	44
Actual blowing time	5	19
Copper cast, tons		52.3
Tons per 24 hr., based on elapsed time		170
Tons per 24 hr., based on actual blowing		236

In the paper already mentioned, D. H. Browne has given some details of the results attained with the use of basic lining for converting nickel-copper matte. The Pierce-Smith converters are 37 ft. long and 10 ft. diam., taking an initial charge of about 60 tons of matte. Addition of siliceous material, blowing, skimming of slag, and addition of matte proceeds until at the end of 30 to 50 hours blowing time the converter contains 70 to 80 tons of finished product derived from 300 to 400 tons of matte. A single lining lasts for 3000 or 4000 tons of finished product; an 80% copper-nickel matte. An interesting modification of the ordinary construction is that oil is used in the hydraulic equipment for operating the converter in place of water, to obviate trouble from freezing in the cold climate of Sudbury.

Blast-Furnace Practice

The event of most interest in blast-furnace practice during the year is the construction of a 42 by 106-in. oil-fired Colorado Iron Works Co. blast-furnace by the Pioneer Smelting Co. at Corwin, Pima county, Arizona. This was to have been blown in during May, but no account of the results obtained in practice has been published. An interesting account of the unusual practice at El Boleo[10] appeared during the year. The average slag there contains 52% SiO_2, and no forehearth is employed on account of the rapid chilling of so acid a slag. The slag flows continuously through 4-in. ports, and carries only about ½% copper, as the high manganese content gives it a considerable degree of fluidity.

Hydrometallurgy of Copper

The problem of recovering the copper from the tailing of ore-dressing plants has greatly stimulated research on the hydrometallurgy of copper, but the results of experimental work are usually unavailable for publication. It is generally known, however, that work with the Laist process, which involves leaching with H_2SO_4 and precipitating with H_2S generated from matte, thus regenerating the acid, is progressing favorably. The Shannon Copper Co. has done much experimental work on leaching tailing, but is unwilling to disclose the results. As J. W. Bennie, the superintendent, has recently patented a method of heap-roasting and leaching in which the heaps during roasting are sprinkled with solutions containing $FeSO_4$ or NaCl, or both, to aid in converting the copper into sulphites and sulphates as completely as possible, followed by leaching and subsequent precipitation, presumably this is the procedure followed.

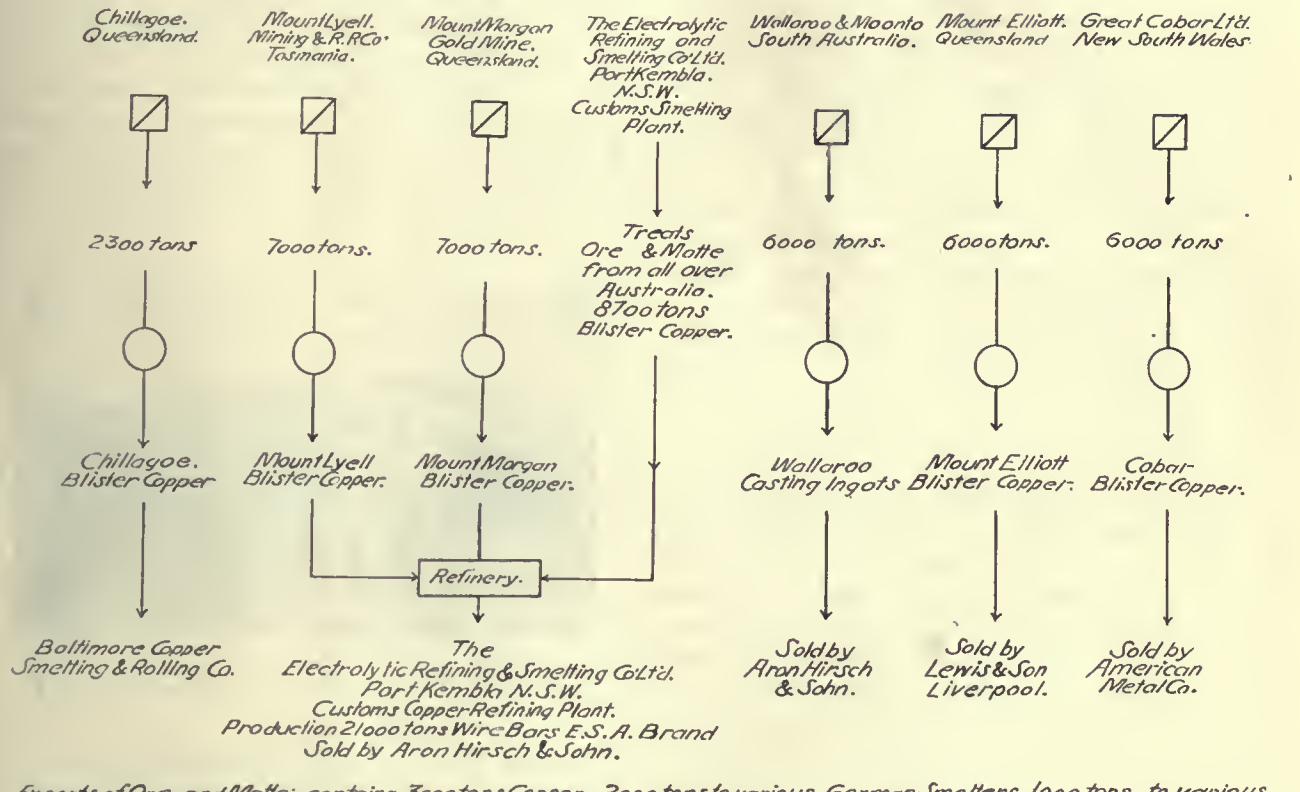
A leaching plant for oxidized ores is in process of construction at the Bullwhacker, at Butte. The Bradley plant, at Anaconda, of which large things were predicted last year, has been shut down nearly all the year, having treated only a few tons, and it is at least doubtful if the process can ever be put upon a profitable working basis. Leaching experiments have been made at the Braden, but no results have been published. An interesting and valuable book upon this topic[11] appeared during the year, and

[10] *Mining and Scientific Press*, May 18, 1912, p. 700.
[11] 'Hydrometallurgy of Copper,' by W. E. Greenawalt.

reference should be made to it for fuller details regarding hydrometallurgy.

Flotation Processes

The use of flotation for the recovery of copper from its ores, though perhaps strictly a branch of ore dressing, which is covered in another article, is so significant that reference must be made to it. The development in practice of flotation processes, as well as the settlement of the great mass of litigation concerning rival patent claims, has until recently been largely confined to Australia, though some small plants are at work in Europe. Last year the principal controversies were settled by compromise, and the Minerals Separation, Ltd., at once proceeded to introduce its process in North and South America. The largest plant built as yet is that at the Braden mine, in Chile, where a 600-ton unit has been completed, two more are under construction, and it is planned to finally increase the capacity to 3500 tons per day. During November the first unit made 81.6% recovery as compared with 61% in the new 2000-ton wet concentration mill recently completed. Test runs by flotation gave recoveries as high as 95%, and when the process gets into normal working order a recovery of 85% is expected to be maintained in practice. At Butte an extensive series of tests have been in progress during the year to determine the best type of plant to construct for re-treating the accumulated tailing of the old Butte Reduction Works, about 1,500,000 tons containing 10% copper. The Minerals Separation process and the McQuisten tubes are used in competition to determine which will give the maximum saving at the minimum cost. Final announcement has not yet been made. McQuisten tubes have so far only been used in the concentration of zinc ores, and their application to copper metallurgy is of great interest. It is most unfortunate that the advent of the Minerals Separation process in this country should be signalized by litigation such as has been the bane of American industrial development. The Butte & Superior Copper Co. has been sued by the Minerals Separation, Ltd., for infringement in the use of the so-called Hyde process, but it is to be hoped that metallurgical progress will not be hampered by further litigation. A number of companies have been carrying on careful experiments with flotation, but no announcement of plans has been made as yet.



AUSTRALIAN SMELTING AND REFINING PLANTS.

Refining and Marketing of Copper

Refining and marketing are no less important stages in the production of copper from its ores than roasting and smelting. In two admirable articles W. R. Ingalls[12] has discussed the selling of copper in all its somewhat complex phases. In this connection I have prepared charts showing the relations between the various mines, smelters, refineries, and metal-selling companies. For the accompanying chart showing these relations in Australia, I am indebted to the courtesy of Benjamin Magnus, manager of the Port Kembla refinery. Charts showing similar relations in America have been prepared, but considerations of space make it necessary to defer their publication. T. Hasegawa[13] has briefly described the new electrolytic refinery constructed by the Furukawa Mining Co. at Nikko, Japan. The Walker arrangement of electrodes is used.

Progress in Ore Dressing

By Henry S. Munroe

Hand Sorting

Much has been written[1] on the advantages of hand sorting of ore before treatment by mechanical means; for the removal of waste rock, for the saving of rich ore, and for the separation of minerals of nearly the same specific gravity. This preliminary treatment of the ore is becoming increasingly common, resulting in increased output for the mills, diminished losses, and larger net profit. In one case[2] annual loss has been changed to profit largely through sorting. Attention should be drawn to a fourth application of hand sorting deserving of more frequent use. In some cases a portion of the ore contains valuable mineral in microscopic particles too fine to be released by crushing or saved by mechanical means. Sometimes such ore is rich enough for metallurgical treatment or can be used with profit as a flux with incidental saving of the valuable metal. In such cases it may pay to sort it out by hand before it is crushed. Otherwise such material will go almost wholly into the tailing and be lost.

The cost of hand sorting bears close relation to the amount of material picked out, so that the cost per ton of material treated will be low when a small quantity only of rich ore, or poor rock, or other material is to be removed. In comparing the cost of hand sorting with mechanical treatment, account should be taken of maintenance and amortization costs, which will be small for hand sorting on account of the simplicity of the apparatus required.

The most important improvement[3] in the mechanical appliances for hand sorting consists in the general use in South Africa of two-deck sorting tables in which the lower deck is used for the hand-picked material, while the bulk of the ore remains upon the upper deck. The material on each deck is scraped by plows into appropriate bins or chutes at the end of the revolution of the table. The same result is secured by the use of two conveying-belts, one above the other, as at the El Tigre mine.[4]

Preliminary Washing

A simple and efficient method[5] of washing ore for the removal of tough clay is by the use of a small jet of water under considerable pressure. At the Totok Gold Mine, Celebes, Dutch East Indies, F. A. Killik uses a small giant with a 7/8-in. nozzle, with a head of 125 ft., using 15 to 20 cu. ft. of water per minute to wash 200 tons per day. The washing is done in a large chute or bin with converging sides and a steeply inclined bottom, the lower end of which is partly closed by two board partitions, one at the top and the other somewhat in advance at the bottom. This form of opening doubtless contributes much to the success of the plan. There is provided also a small platform on which the washing may be completed before the washed ore is finally swept off by the force of the nozzle. In the discussion of Mr. Killik's paper, A. G. Charleton describes the use of the same method in a tin mine in the East. At this mine the washed ore was further treated in a revolving trommel with inside blades. R. H. Richards[6] describes the use of a jet washer with a 1½-in. nozzle using 50 lb. pressure, the work being done in an iron cylinder 2 ft. in diameter by 6 ft. long with a large feed-opening above. This arrangement proved much more efficient than a log-washer used at the same plant. According to Killik, the cost of washing by this method is low, and the simplicity and cheapness of the plant warrants the consideration of this method where work of this kind is to be done. The amount of water used with a 7/8-in. nozzle is probably no more than that required by other methods of washing, and even if the water be pumped, the power required will be small in comparison with that consumed by log washers or wash drums.

STEEL ORE-BINS ON CONCRETE FOUNDATION, CHINO MILL.

Storage and Feeding of Ore

At many of the large mills recently constructed, cylindrical steel bins have been built, and in some instances these have been provided with concrete bottoms. The next step is likely to be the construction of cylindrical bins of reinforced concrete. This construction would have the advantage over steel bins of greater durability and, with proper arrangements for handling the material and for the construction of the forms, should be built at moderate cost. Flat-bottomed ore-bins filled with waste rock, so as to form a sloping bottom, have been adopted in rock-houses built for the Copper Range Mining Company.[7]

H. P. Stowe[8] advocates the construction of flat-bottomed bins and filling the additional space with ore, thus obtaining additional storage for use in emergencies. He also instances a case in which it was possible to rebuild such a bin without interrupting the operations of the mill. This work was made possible by the space available under and around the temporary chute constructed in the bin to carry the ore from the dump-cars to the crushers. If the extra cost of handling the ore at the bottom of such bins, and the interest charge on the working capital locked up in such ore be considered, it may prove that the additional storage is secured at considerable cost.

F. E. Shepard[9] emphasizes the importance of delivering the fine ore from the grizzly and the coarser ore from the crusher at the same point in the mill-bins in order to secure a uniform distribution of ore in the bin and a uniform feed to the mill. Mr. Shepard further suggests the preliminary bedding of the ore, as is now done in smelting plants, to secure still greater uniformity in the mill feed. The tendency in recent years, however, has been rather to overcome irregularities in mill feed by the adoption of concentrating machines providing a storage of mineral under treatment sufficient to overcome minor variations in richness or quantity of feed. It is this that has led to the extended use of vanners and riffle tables instead of the more sensitive film tables, such as the round table, Rittinger table, and cross-flow belt table. It may well be that further advance in ore-dressing practice may be secured by the use of the more sensitive type of machine and the adoption of the above suggestion. Mr. Shepard's attention doubtless has been called to this point from his experience with the Richards pulsator jig, which has small storage capacity and is exceedingly sensitive to variations in the richness of the material treated.

Crushing

It is much cheaper to crush rock and ore by mechanical means than by blasting or sledging. This fact is illustrated by the erection of mammoth crushers of different types capable of handling large masses and thus saving the expense of breaking by powder or by hand. Notable examples of this are found in the Lake Superior copper region,[10] where mammoth jaw-crushers 24 by 36 in. and 24 by 48 in., of the Blake type, have been in use for many years. The Traylor Engineering Co.[11] recently built for the contractors at the Kensico dam, at New York, a plant for the production of crushed stone containing one 60 by 84-in. Blake crusher and one 30 by 72 in., followed by a pair of 30 by 60-in. rolls, the total capacity of the plant being 500 cu. yd. per hour. At a limestone quarry at Martinsburg, West Virginia,[12] a pair of Edison giant toothed rolls, 6 ft. in diameter by 7 ft. face, are used as the only crushing machine for reducing this rock to 7 or 8-in. pieces. These rolls readily crush blocks as large as can be handled by a 100-ton steam-shovel, pieces 15 tons or more in weight, and it is said could deal with cubes 7 ft. in size which would weigh 28 tons. The capacity of these rolls is 1000 tons per hour. Additional rolls are to be added to produce smaller sizes. Giant rolls are in use at the Edison portland cement works, where they have given satisfactory service with low cost for repairs and replacements. Similar rolls were installed at Franklin Furnace, New Jersey, for the crushing of zinc ore, but these have been long since abandoned.

Gyratory crushers are taking the place of the Blake swinging-jaw type in most of the mills recently built. The great advantage in the use of this form of crusher is not only its large capacity, but the great saving in power effected, amounting to 40 to 60%. This offsets the more complicated design, which tends to increase repair and maintenance costs and loss of time in the mill. Gyratory crushers require somewhat greater height between the feed and discharge-level than the Blake type of crusher. This advantage, however, has been lessened by the introduction of the pillar type, in which the gyratory motion is about a fixed vertical axis instead of the pendulum movement of the earlier type.

The Symons disc crusher[13] has attracted much attention and constitutes a new type of crushing machine likely to prove of importance. In this the ore is crushed between two saucer-shaped discs revolving at high speed in the same direction, one of the discs being given a gyratory movement. The ore is fed at the centre and escapes by centrifugal force at the circumference of the discs, thus securing a maximum length of discharge opening where the crushed material can escape. In this it differs from all other types of crushing machines, where the length of the discharge opening is either equal to the feed opening, as in rolls and in jaw-crushers, or is of less length than the feed opening, as in the gyratory type. The screen analysis of crushed material shows a remarkably small proportion of slime and, if this be confirmed by other tests, shows that this crusher is likely to do even better work than rolls. As designed at present, these machines crush to ¼ or ⅛ in. only, but it is quite possible that their field can be extended to the production of finer material. At the Federal mill No. 3, at Flat River, Missouri,[14] the crushing plant has been remodeled during the present year by replacing jaw crushers and coarse rolls in each section by two No. 7½ Symons gyratory crushers and four 48-in. Symons disc crushers. The effect has been a reduction of about 80 hp. in operating load and an approximate increase of 1000 tons in the crushing capacity of the mill. The saving in power, however, is mainly due to the use of gyratory crushers instead of the swinging-jaw type.

At other plants in which the Symons disc crusher has been chosen, the usual difficulties attending the

[14]Guess, H. A., private communication.

introduction of a new type of machine have been experieneed in the breakage of shafts and of erushing parts. These accidents are due to the presenee of bolts or of drill-steel and similar material to the feed. The only safety devices in the machine are the 15 or 16 spider bolts whieh hold the fixed erushing disc to the revolving axis. The breaking of these bolts brings excessive strain on the moving parts. At the Federal mill and other places this difficulty is overeome first by the use of eleetro-magnets to remove iron and steel from the feed and also by loose belts on the pulley giving the gyratory movement to the axis. I am informed[15] that the 1913 design of disc crusher will be of mueh heavier eonstruction and will embody minor improvements which will add materially to the ease of replaeement of worn parts.

At the Round Mountain mine,[16] Nevada, two crushing and sereening plants have been built underground. Each plant includes a 12 by 20 crusher, an 18-in. belt-conveyor, and a 10-ft. by 40-in. screen over a loading pocket. The fine material is sent to the mill and the coarse waste roek, amounting to 66%, to the dump. Before these plants were built the waste was 54%, and contained valuable ore now saved.

High-speed crushing rolls of large size are being used in most of the recent mills. Among these may be mentioned the 20 by 72-in. rolls in the coarse-erushing plant of the Chino mill,[17] weighing 175,000 lb. and having a capacity of 450 tons per hour, crushing from 2½ to ½ in. and, at Miami, the two 24 by 54-in. rolls used for erushing from 2 to ½ inch in the coarse-crushing plant. For fine crushing, 16 by 42-in. rolls are used in many of the large mills, while few of the recently built mills eontain rolls less than 15 by 36 inches in size. At the Steptoe Valley concentrator in some of the sections an elaborate system of stage-crushing has been adopted; crushing from 1½ inehes to 2 mm. in four or five stages, the reduction in eaeh case being about 50%. In most mills the crushing by rolls is in two stages only, the reduction being usually four to one.

At the Buffalo mill at Cobalt the erushing is in three stages, from 1½ to $^3/_{16}$, or 50% at each stage. At the Utah, Chino, and Ray Consolidated the fine crushing is in a single stage, the rolls being operated in closed circuit with a fine screen having $^1/_{10}$-in. openings at Chino and $^1/_{16}$-in. at the other mills. One of the sections of the Steptoe Valley concentrator has been equipped on the Utah plan. It will be interesting to have data from this mill as to the eharacter of the crushing by this, as compared with the four-stage plan in other sections. When rolls are operated in closed eireuit with a fine sereen, coarse material tends to accumulate. I have known instances where tests have shown two and three times the amount of actual feed in the eireuit. Under such conditions a certain degree of choke feeding becomes inevitable, and a large proportion of colloidal material will be produced.

The Traylor Engineering Co.[18] has built a large number of heavy crushing rolls with an automatic lateral adjustment device attaehed to one roll by whieh the roll shaft is slowly moved back and forth endwise ½ in. during 120 revolutions. This is effeeted by a worm wheel and spur gearing operating an eccentric shaft in the bottom of the thrust box. This device is in use at the mill of the Miami Copper Co., the Butte & Snperior Copper Co., and elsewhere. The effeet of this lateral movement is to prevent the corrugation or channeling of the rolls and to lessen the end-thrust whieh is one of its effeets. The same result may be secured by the use of flanged rolls[19] with a feed-chute having an angle-iron lip turned upward, this angle iron being eut in the form of a convex eurve and thus feeding more ore toward the ends of the rolls than in the middle. Flanged rolls are in common use in the Joplin lead region of Missouri and have proved satisfactory at the North River garnet mill in Warren county, New York.

One of the most interesting of recent changes in mill practice has been the instant and wide acceptance of the Hardinge conical tube-mill. Tests have been made for a period of seven months by the Miami Copper Co., and tests of shorter duration have been made by David Cole at the coneentrator of the Arizona Copper Co., at Morenci, and it has been pretty well demonstrated that the new mill fills a very important place for the fine grinding of ores in which the mineral is finely disseminated. Within the past two years a large number of these mills have been placed in the Lake Superior concentrators for the re-grinding of middle produets and tailing, and a new re-grinding plant for the Calumet & Hecla M. Co. is now building which will call for 64 of these mills. Reeently I had the opportunity of examining screen analyses of the product of these mills from many sourees, and, while the results leave mueh to be desired from the standpoint of sliming, it is quite clear that the results so far obtained show less eolloidal material than is produced by the high-speed Chilean mill, and no more than from the Huntington mill, whieh heretofore have been the aceepted maehines for very fine grinding for concentration purposes. The Hardinge mill is evidently destined to take the same place in concentration that the long tube-mill occupies in cyanide practice. It is more than probable that equally good results, so far as the uniformity of the product is concerned, would have been seeured by the use of short tube-mills; that is, mills less than 15 ft. in length; but certain advantages are claimed for the conical over the cylindrical form which may prove to have good foundation. It is probable that further experiments with the Hardinge mill may show that the amount of colloidal material can be redneed by changes in some one or more of the adjustments. Up to the present time those using the new mill have followed closely the lines whieh have been developed for the tube-mill in cyanide practiee where, however, the production of slime is an object to be attained rather than avoided. In two respects practice with the Hardinge

mill seems to be developing along new lines, namely, in the amount of water in the pulp and in speed. The water used is rarely less than 60 to 70%, and sometimes reaches 80% or more. The mills are usually driven at higher speed than would be considered good practice with a cylindrical mill of the same diameter. It has been attempted to use the Hardinge ball-mill to replace rolls, but in this field the new mill has not proved entirely successful. It will undoubtedly serve well as a substitute for stamps where the production of a certain amount of fine material is not objectionable.

In considering the production of a finely pulverized material for concentrating purposes, the fineness of crushing must be proportioned to the fineness of the valuable mineral in the ore, and in some cases, at least the crushing of all the material to go through 100-mesh, may be necessary. It does not follow, however, that it is desirable to crush all or any large part of the material so as to go through 200-mesh, and it is quite certain that the production of colloidal material is to be avoided. In the final pulp crushed to 100-mesh it is not unlikely that fully half of the material below 200-mesh will be produced in the preliminary crushing by jaw crushers and rolls, and it is quite as important to see that the preliminary crushing is conducted on proper lines as well as the final crushing in the tube-mill.

Crushing by stamps finds a limited application in concentrating mills, their use being confined chiefly to the stamp-milling of native copper ores at Lake Superior and of gold ores where concentration is an adjunct to amalgamation and to the cyanide process. Nevertheless, the crushed material produced by stamps, under favorable conditions and with proper design and operation of the crushing-plant, is but little inferior to the pulp often produced by rolls and fine-crushing machines that are operated without regard for the conditions which tend to increase the amount of sliming. I have in my possession samples of crushed material from mills using rolls only, which contain much more slime than would be produced by stamps properly run. At the Edison cement plant choke-feeding of rolls gives a product nearly all below 200-mesh.

Sizing

The most interesting and important improvements in sizing in recent years are the Rowand-Edison system for dry screening and the Callow belt-screen for wet sizing.[20] In the former system the screens, inclined 45°, are placed in steps, with baffles between, in an inclined screening chute so arranged that the material passes over 10 or more screens of the same mesh, each screen being quite short, not more than 9 in., and the fall of the ore being interrupted each time so that the velocity of the falling material remains uniform and is not accelerated. This screen proves to have a large capacity and does excellent work, the proportion of undersize being much less than with ordinary shaking and revolving screens. The best results are secured when the ore is dried, in which case the wear on the screen surfaces is negligible. The wear on the screen plates is increased when the ore contains even 1% of moisture. Screens of this type, modified in design by Mr. Rowand, are in use on a large scale at the mill of the New Jersey Zinc Co. at Franklin Furnace.

For the screening of wet ore the well known Callow screen, in which the material is washed through a moving endless-belt of wire cloth, has made it possible to extend the field of screening to very fine material which formerly could not be sized on account of the high cost of such work. These screens have large capacity and make a clean product. A new form of screen, styled a revolving grizzly,[21] consists of a series of hard steel rings of V cross-section assembled with distance pieces between to form a cylindrical screen. A screen of this type with 30-mesh aperture is said to handle large tonnage of coarse material with little wear.

Classifiers

The Richards-Janney and the Richards hindered-settling classifiers have found extended application in many of the largest concentrating mills. The pulsator classifier does not seem to have had as much success. A new form of the pulsator classifier[22] in which the adjustments have been greatly simplified has been introduced, also a single-cell pulsator classifier[23] designed to be attached to mill launders.

Conical settlers or Callow cones have replaced the rectangular spitzkasten in almost all of the modern mills. The credit for the first use of these cones, however, should be given to C. B. Parson, of Bonne Terre, Missouri, who built a series of settlers of this type in the first Doe Run mill twenty-five years ago. The advantage of the conical type of settler is that the great length of discharge edge produces a very slow surface current and consequently greatly facilitates the deposition of fine material. The conical tank with radial flow will have several times the capacity of a rectangular tank where the discharge is over one edge only. R. H. Richards has shown that the surface current of box classifiers produces an overturning current, descending on one side of the box and ascending on the other, which affects the whole mass of pulp. This overturning vortex current carries down much fine material which would otherwise be carried over by the horizontal current. This accounts for the poor work done in the classification of fine slime in the old spitzkasten. In a conical tank the vortex current induced by surface flow takes the form on an annular ring like the smoke-ring made by a locomotive. This vortex ring has the same effect as the overturning current in the box form of classifier, so that the slime is no better classified in the cone than in the old box type.

Some years ago, in the laboratory of the School of Mines, Columbia University, I introduced the use of inclined baffle-plates for box classifiers and conical baffle-plates for cone settlers, so arranged as to prevent the formation of these overturning currents. These baffle-plates have been successfully used in

[20] Richards, R. H., 'Text-Book of Ore Dressing,' pp. 203, 218, and 'Ore Dressing,' Vol. III, pp. 1345, 1358.

[21] Ruthenberg, Marcus, *Met. & Chem. Eng.*, Vol. X, p. 412, July 1912.

[23] Shepard, F. E., *ibid*, Vol. 93, p. 546, March 16, 1912.

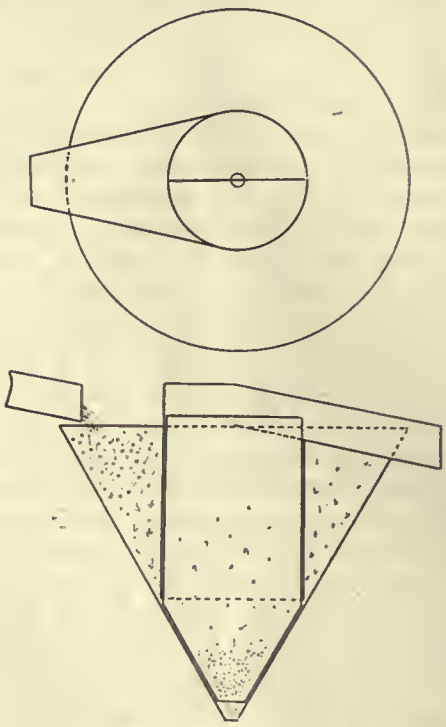
practice and have been found to increase the capacity of the settling-tanks, both rectangular and conical, as well as to produce a more uniform product. Similar baffle-plates have recently been used at the Sons of Gwalia mine in Australia[24] and at the Kyloe copper mines, New South Wales.[25] In these instances a very large number of baffle plates are used, many more than are needed for the purpose. Inclined baffle-plates not only prevent the formation of overturning currents, but also promote the settling of the material. The particles as they fall tend to leave the swifter moving current and fall into the slower-moving portion, which is retarded by friction on the surface of the baffle-plates. The settled material slides down the plates in this slow-moving current until it reaches the discharge openings at the bottom. In the use of the conical baffle-plates that I designed, the descending current is gradually throttled by diminishing the openings in the conical baffles, and the overflow current at the top is maintained of uniform velocity by gradually enlarging the space between the upper edge of the conical baffles and the surface of the water.

Separation of Sand from Slime

The separation of sand from slime is a problem arising frequently in concentrating mills for the separation of material for re-crushing, for facilitating the work of sand classifiers, and to divide at once material going to slime treatment from that to be treated on jigs or sand tables. It is also necessary when conditions make the separate handling of sand and slime tailing desirable.

The separation of sand and slime can be effected by the use of screens, classifiers, jigs, and tables, and by mechanical appliances and de-watering devices designed for the purpose. Small settling-cones are frequently used for the preliminary separation of sand from slime-settlers and slime treatment. The addition of baffle plates to such cones makes this separation more perfect and prevents the entangled slime finding its way to the sand-classifiers and sand-concentrators. The Caldecott cone is used in South Africa to separate sand from slime, the sand going to tube-mills and the slime to cyanide treatment. An improved cone[26] designed by W. G. Mosher has been generally adopted in the Butters plants. This consists of a cone with a large inner cylinder prolonged as a cone to near the bottom, the annular space between the two cones being ½ to ⅝ in. The feed enters the outer cone and the overflow is discharged by a spout from the inner cylinder passing through the wall of the outer cone. A longitudinal vertical partition is placed in the cylinder to prevent eddy currents, which may be produced by the spigot discharge. The rising current in the cylinder is of low velocity and free from bubbles. It is stated that by the introduction of this cylinder the capacity of the cone has been doubled in spite of the small discharge exit from the inner cylinder.

Mechanical sand and slime separators are for the most part modifications of the well known Dorr sand-classifier and are designed to elevate the sand from a large settling-tank by mechanical means. In the Dorr classifier this is done by a reciprocating



IMPROVED MOSHER CONE.

mechanism carrying a number of scrapers. In the Akins classifier[27] this is replaced by a revolving frame carrying a continuous helical scraper blade. In the Esperanza-Federal machine[28] the scraping blades are attached to an endless chain. The Argall classifier[29] contains two helical screw conveyors of long pitch and moderate diameter which raise the sand from the bottom of a conical settler with overflow at the circumference. Finally, there are several different types of shovel de-waterers in which the sand is raised from a tank by a vertical or inclined wheel carrying scoops or shoveling blades.[30] In the Federal mill at Flat River, Missouri, Mr. Guess has adapted the principle of the Esperanza drag to the delivery of tailing even from the jigs. This permits cleaner table and vanner work and economizes water.

[Jigging, magnetic separation, electrostatic separation, decrepitation, and flotation will be discussed in the continuation of this review to be printed January 11.—Editor.]

Chrome iron is actively mined in Russia, that country being one of the largest chrome-iron producers in the world. The reserves are principally in the Urals.

Quicksilver Production and Prices

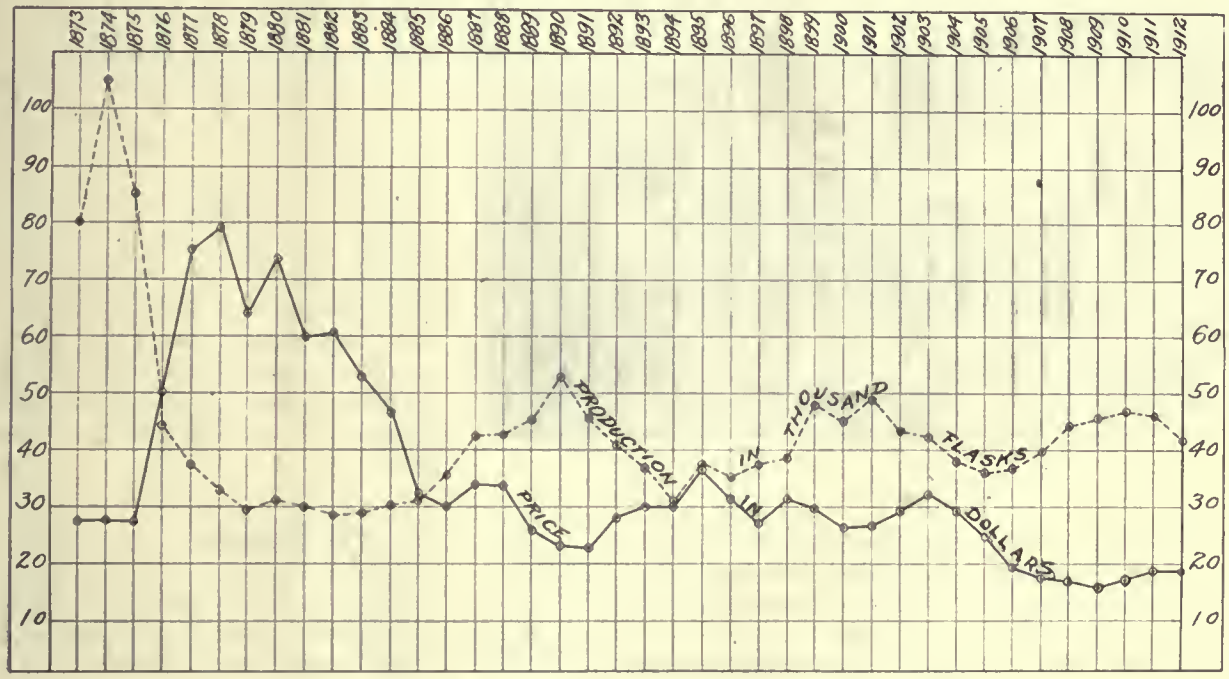
By Clifford G. Dennis

The quicksilver industry for the year 1912 has been quietly prosperous. The total production has been approximately the same as that of 1911, when it amounted to 21,256 flasks of 75 lb. each. Production in 1912 may be estimated at 23,650 flasks, of which California produced 18,150; Texas, 2500; and Nevada, 3000.

The powder and cap manufacturers continue to be the largest consumers, although considerable metal was used by the makers of electrical appliances. The usual amount was sold for medicinal purposes and use in the arts. The consumption in metallurgy decreased. No new uses have been found, but the fact that electrical appliance manufacturers are taking more each year is encouraging. The diagram published herewith, showing the California quicksilver production for the past forty years, with the price per flask during that period, indicates that the production is in no way regulated by the price, but that each company produces to its limit as long as there is ore that can be mined and reduced with profit at the prices set by the London market. A rise in price results in a slight increase in production due to the small producers, but as this increase is immediately met by the necessity to export, the average price is immediately reduced. This terminates the activities of the small producers who must meet high working costs.

California remains the chief producer, San Benito and Santa Clara counties yielding the bulk of California's production with the balance scattered over seven counties. In Texas, Brewster county alone yields quicksilver. Nye county yielded the bulk of Nevada's quicksilver, with a small production from three other counties. Oregon contains a few small mines, the Black Butte mine being best known. At the New Idria mine in San Benito county, California, active development has been carried on during the past year and this property is probably in better shape as to ore reserves than at any time for several years. The Guadelupe mine in Santa Clara county, California, had a remarkable production record for several months and will, no doubt, be able to resume this production when development work, now under way, is completed.

The Chisos mine, in the Terlingua district, Brewster county, Texas, is the principal producer of that state. The Chisos is situated in a formation geologically above any of the old producers of the Texas mines, and beyond a major fault that occurs between it and the older producers. The deepest workings at 400 or 500 ft. have not, as yet, penetrated the underlying formation that was so productive in the old mines, so that a long uninterrupted period of production may be looked for from this property. It will be interesting to learn what will happen when the Chisos workings penetrate the Lower Cretaceous formations. The older miners, who did all their mining in this lower formation found practically no metal in or above a thin overlying shale stratum but extraordinarily rich ore immediately below it. In fact, it is safe to assume that 70% of the mercury produced from the Terlingua fields was taken from a zone within 50 ft. below this stratum of shale. The interesting point now is what conditions will be met with as the Chisos workings enter the Vola limestone and Del Rio shales that overlie the zone that was so productive in the eroded area. Will ore occur in the shales and below it, or will the shales mark the termination of all ore downward? If ore occurs below the shale in this area, as it did in the eroded area, the Chisos mine is but in the infancy of its productive period and no doubt, owners of other properties that have only fair prospects on the surface will be encouraged to sink to the zone below the shales in the hope of finding bonanza ore.



CALIFORNIA PRODUCTION OF QUICKSILVER AND PRICES, 1873 TO 1912, INCLUSIVE.

The Mercury Mining Company's property at Ione, Nevada, was the principal producer in that state. This property was equipped with a 25-ton furnace of the Scott type and seven brick double condensers, in 1911. The reduction of ore began in January, 1912, and has been continuous. The ore occurs along and adjacent to a main fault that courses through the entire district. This fault has itself been subsequently faulted, and crushed areas of rhyolite, granite, chert, and limestone, highly altered, occur along the faulted zone. The metal occurs in the breccia of these subsequent faults and is distributed through the crushed areas in irregular bodies. The main fault bears the relation to the ore deposits that a trunk railway does to its branches. It has been the means of transport, but carries little commercial ore. The future production of the district depends on the number of these subsequent faults and crushed areas found along the main fault and the methods pursued in tracing the ore that undoubtedly occurs in and along them.

FURNACE OF THE MERCURY MINING CO., IONE, NEVADA.

It is reported that a 10-ton furnace of Scott type, with condensers, is to be erected in the Fluorine district, which is situated about five miles easterly from Beatty, Nye county, Nevada. This furnace is to be in operation by January 15, 1913. The mine is reported to have a large quantity of high-grade ore available for treatment.

Arizona did not produce any quicksilver in 1912, but the Cinnabar Development Co., which is developing the old Colonial mine situated near Ehrenberg, reports good ore in the lower workings. The ore in this mine occurs in shoots along a well defined fissure. In the upper levels the ore showed undisputable signs of leaching. Bunches of very rich ore were found within the shoots but careful study revealed that these bunches had been protected from leaching by clay gouges along fault planes due to pressure. It is likely that development in depth has reached a point below the zone affected by leaching and that the metal is distributed through the ore more uniformly. Discoveries of cinnabar have been reported from near Roosevelt, Arizona, but no reports of any production from this locality have been noted.

QUICKSILVER PRICES, 1912

Month.	London.	New York.	Logical Import.
January	$40.75	$41.50	$46.44
February	40.14	42.00	45.83
March	40.75	44.00	46.44
April	41.97	41.00	47.66
May	40.14	41.00	45.83
June	39.53	41.00	45.22
July	38.92	42.50	44.61
August	38.32	42.50	44.01
September	41.36	41.50	47.05
October	37.71	41.00	43.40
November	37.09	41.00	42.78
December	36.49	40.00	42.18
Averages	39.43	41.58	45.12

The price received from quicksilver in 1912 has been considerably lower than in 1911. In that year the average price was $47.58—in 1912, $41.58. The table above shows the London price, the New York price as actually received for quicksilver, and the logical New York price based on the London price plus duty and freight. It permits interesting comparisons.

There have been practically no exports during the year, so that it is evident that the several sellers of quicksilver have traded the price down to get the business, and that American buyers have received for their metal less than was consistent with the world's prices.

Oil Exports

Mineral oil exports from the United States in 1912 will show a larger total, both as to quantity and value, than in any earlier year. The quantity exported will, according to the latest figures of the division of Statistics of the Department of Commerce and Labor, approximate 1800 million gallons, or an average of 5,000,000 gal. per day, and the value $120,000,000, or an average of about one-third of a million dollars per day. The history of the export trade in mineral oils touches the half-century line with the year 1912, the first statistical record of the exportation of mineral oils being that of the year 1862, when the value of the exports, including both crude and refined, was about $1,500,000. By 1872 the exportation had risen to 34 million dollars: in 1882, 51 million; in 1892, 45 million; in 1902, 72 million, and in the fiscal year 1912, 112 million: while in the calendar year 1912 the total will approximate 120 million dollars. The total value of the mineral oils exported in the half century since the export movement began is almost three billion dollars, and the total during the past decade nearly one billion dollars.

The distribution of the mineral oil exports extends over a wider area than perhaps any other single article. Europe is by far the largest customer, taking a little more than one-half of the lubricating oil and over one-half of the gasoline and naphthas exported.

Iron Ore, Pig Iron, and Steel During the Year

By G. H. Cushing

Iron Ore Shipments

Shipments of iron ore from the Lake Superior region by the Great Lakes for the season of 1912 were unprecedentedly heavy, running to 47,435,777 gross tons. Owing to the fact that shipments were light both in April and November, the six months from May to October, inclusive, showed a record movement of 7,000,000 tons per month. Iron-ore shipments for 1911 were 32,130,411 tons. This makes the increase for 1912 over the shipments for the preceding year 15,305,366. Shipments for 1912 were almost 5,000,000 tons in excess of the largest record previously made.

The shipments of iron ore by ports for November and for the lake season of 1912, as compiled by the *Marine Review*, were as follows:

Port.	Nov. 1911.	Nov. 1912.
Escanaba	513,790	560,328
Marquette	244,135	214,431
Ashland	168,909	414,224
Superior	800,531	1,140,767
Duluth	476,563	1,080,066
Two Harbors	514,325	662,858
Totals	2,523,253	4,072,674
1912 Increase		1,549,421

Port.	Dec. 1911.	Dec. 1912.
Escanaba	.....	10,428
Two Harbors	.....	4,151
Total	.....	14,579

Port.	Season 1911.	Season 1912.
Escanaba	4,278,445	5,234,655
Marquette	2,200,380	3,296,761
Ashland	2,429,290	4,797,101
Superior	9,920,490	14,240,714
Duluth	6,934,269	10,495,577
Two Harbors	6,367,537	9,370,969
Totals	32,130,411	47,435,777
1912 Increase		15,305,366

While the volume of business was big, prices were reduced 65 to 75c. per ton under those prevailing in 1911. This was clearly an effort to induce a return of activity in the iron and steel trades, and was so understood by all concerned. The activity in the iron and steel business came, but not exactly in response to this reduction in price. The cut in ore prices was made early in the year, but the upturn in the steel business did not appear until September. This suggests clearly that the improvement was traceable to crop and general business conditions rather than to the change in the basing prices of ore. Because general business is now upon such a firm footing, iron ore prices have been advanced again on sales already made and in prospect for 1913 delivery. Those prices are 55 to 65c. per ton higher than the prices charged for 1912, and therefore still 10c. per ton below the prices charged in 1911. On sales already made for next year, the guarantee of iron content has not changed, being 51.5% for non-bessemer and 55% for bessemer ores.

Stock Piles

While shipments of iron ore from the Lake Superior region were heavy enough to have afforded foundation for the large expansion of the iron and steel trade, which came with the last four months of the year, it must be definitely understood that neither the quantity nor the analysis of ore shipments determine either the quality of pig iron made or the amount of that pig iron. Production of ore from the Lake Superior region has been remarkably heavy for the past five years. Not all of the ore has been going into immediate consumption, and consequently considerable quantities have been placed in storage on the lake docks and in the furnace stock piles. The Northern iron business, or that which is dependent upon the Lake Superior region, has had rather hard sledding for the past five years. This was true because general business of a character to demand steel has been slight, because Southern iron has sold extensively in Northern markets, and because the Eastern steel trade has been drawing a large and increasing amount of ore from mines in the northern part of Cuba and from Sweden. On these various accounts Northern ironmakers have not used the ore that has been moved from the Lake Superior region. Furnaces in the Chicago district; along the south shore of Lake Erie; in the 'Valleys'; and in the Pittsburgh district have been steadily accumulating ore in storage which acted as a reserve upon which to draw when business became brisk along in the fall. Thus the iron ore which was the foundation for the business in the last four months of 1912 was a mixture of held-over ore and that newly shipped, so that quality and analysis of the year's shipments do not define either the amount or quality of pig iron produced.

Steel Mills and Foundries

At the time this review is written, the steel trade from one end of the country to the other is enjoying an astounding period of prosperity. Furnaces that have not been in blast for months, and in some cases not for several years, are now running, and in a good many cases are 60 to 90 days behind urgent orders. One criticism that has been made of the fall period of activity is that it was merely a movement to exchange merchandise for the farmer's cash, and would likely subside the instant the crops were moved and the farmer's harvest of dollars had been garnered into other people's pockets. Without attempting to make any prophecy, it might be said that if such were the case railroad and other improvement programs would not now be so extensive as to take up the iron and steel output for the next 60 to 90 days to such degree as to cause furnace interests to buy their ore supply four months ahead of the time which is customary when the business outlook is not sure. In fact, considering the amount of ore that had accumulated on lake docks and furnace stock piles, and considering that 1912 shipments were almost 5,000,000 tons in excess of any previous record, the fact that buying for

1913 delivery is already on and is heavy, indicates that steel interests are proceeding on fundamental assurances.

Pig Iron Prices

The one check which has been put upon the iron industry in the last four months has been the difficulty of getting coke. Cokemakers had had such a hard time for the preceding five years that no oven company was in the mood to spend large sums of money for building new plants. The companies went into this fall unprepared for the urgent orders which came upon them from every quarter. More particularly, they were seriously embarrassed by a shortage of labor due to the return to Europe of coke-oven workers who went home to participate in the Balkan war. Also, they were hampered by the same thing that has hampered every other business—the shortage of cars. This has brought about a rising cost in production of pig iron which has prevented any great profits for the past year, when the range of prices is taken into consideration. It was not, in fact, until September, that the average price on bessemer iron at the furnace rose above $14.50, and that basic iron rose above $15. Within the year bessemer iron had been 50c. cheaper, and basic iron had been $1.75 cheaper, the latter being, of course, down close to the cost of production. After, however, the period of greater activity set in, prices rose rapidly, and for September bessemer was worth on the average $16, in October $17, and in November close to $17.25. Basic iron in September rose to over $15, and in October to over $16, which price it held through November with another rise declared December 1. The range of prices on bessemer and basic pig iron, by months, for the past two years, has been as follows:

	Bessemer.		Basic.	
	1911.	1912.	1911.	1912.
January	$15.00	$14.078	$13.291	$14.372
February	15.00	14.000	13.603	12.250
March	15.00	14.053	13.750	12.760
April	15.00	14.250	13.750	12.981
May	15.00	14.234	13.400	13.000
June	15.00	14.250	13.060	13.209
July	15.00	14.250	13.000	13.480
August	15.00	14.530	13.000	14.000
September	15.00	15.960	12.667	15.134
October	14.64	17.000	12.515	16.184
November	14.02	17.172	12.278	16.192
December	14.19	.....	12.442	.....
Averages	$14.82	.....	$13.063	.....

Transportation and Docks

In the transportation of iron ore, a number of new influences have made themselves felt. One of them has been the increased speed of unloading cargoes at Lake Erie ports. One vessel there, late in the fall, accomplished the task of unloading a cargo in about 2½ hours. This was even better than the record made by the steamer *Widener*, which, on August 8, unloaded 10,636 gross tons in 2 hr. and 50 min. The latest record is about 30 min. less time on a cargo of approximately the same size, the latter record being all the more remarkable in view of the fact that the ore was transferred to cars instead of to storage piles.

Another influence of importance was the increased size and efficiency of the ships. Not as many vessels have been built in the past few years as had been built prior to the period of depression that started in 1907. Nevertheless, the tonnage of lake vessels has been steadily increasing even with a smaller number in service. Thus in 1905 the gross tonnage of lake bulk freighters was 1,919,285, in 1907 it was 2,442,754, while in 1912 it was 3,135,953 gross tons.

Cuban Ore

Another important influence on the Eastern ore trade has been the rapid development of the ore from Cuba. Just how big an influence this is going to have upon the steel business will depend upon the developments in the next few years. Already those engaged in the Atlantic coastwise business are beginning to get a proper viewpoint on what the Panama canal is going to mean. They are beginning to appreciate that, for coarse commodities, it is not going to mean so much in the way of business through the canal as it will in the expansion of trade to and in the canal. For example, it is beginning to be appreciated that the coal business can hardly expand much beyond that zone, but that trade expansion in the way of bunkering coal in the canal may be considerable. The peculiar advantage of this will be—and Eastern interests are beginning to take account of it—that there will develop on the coast practically a duplication of that condition which brought about the real development of the Great Lakes. That is, there will be a south-bound movement of coal and, with a short run in ballast, a north-bound movement of iron ore. This will cheapen transportation on both iron ore and coal, and consequently bring about an expansion of the trade in both commodities. With any such expansion taking place it may be expected that Cuban ore will be even a larger factor in the East than it is now, regardless of the fact that it has already practically monopolized the business in Baltimore and Philadelphia. In 1912 Baltimore received 1,125,000 tons of this Cuban ore, which was about three times the volume of the heaviest previous shipment. This ore will analyze in iron content a little better than the non-bessemer or Mesaba ores of the Lake Superior region. However, in its other particulars it analyzes close to the bessemer ores.

The influence which this Cuban ore will have upon the Northern markets is offset in a measure by the changed plans and the new attitude adopted by the Southern iron interests. These have their eyes now fixed not quite so much on the highly competitive Northern market as heretofore, but are devoting their attention more to home developments and to the trade to the south. This is likely to take some Southern iron out of the Northern markets, and will leave the Lake Superior region a tremendous uncontested territory, one which is expanding at an enormous rate. In fact, the indications are that the business toward the end of 1912 was in excess of any record that has ever been made in this country, not even excepting the very busy season of the middle of 1907. Even at that, programs of railroad improvement and of expansion of other lines of business indicate a mere start on an era of big things, and the steel trade may be expected to grow in proportion.

REVIEWS BY STATES AND DISTRICTS

CALIFORNIA

By W. H. Storms

The total mineral production of California for the year 1912 is likely to exceed $91,500,000; a gain over the output of 1911 of about $4,000,000. This estimate is based upon inquiry and unofficial returns, though calculated upon what is considered fairly reliable information, and a knowledge of the general condition of the industry throughout the state. As usual, petroleum is the largest factor, the production of oil reaching 87,000,000 bbl., valued at $41,000,000. This value is $500,000 lower than that of 1911, notwithstanding the fact that the volume of production was greater by about 2,500,000 bbl. This is due to the fact that a generally lower price was received for oil during 1912 than in 1911. The increased production is the direct result of extensive new drilling, in both old and new territory. Several 'gushers' were brought in during the year, particularly in the west-side field of the upper San Joaquin valley. The Lost Hills field has been extended largely during the year, as has also that of Belridge, and further extensions of these fields are anticipated. From late information it seems not improbable that Monterey county may became an important factor in production. Test wells were drilled there some time since. These were capped, the derricks and machinery removed, and it was supposed that it had been proved that the field was unpromising. Early in December, several tons of drilling machinery was shipped into this field, and it looks as though Monterey county may become an important producer of petroleum, possibly within the coming year.

The output of gold in 1912 has probably been about the same as in 1911, when it was $20,000,000. There have been some new important developments in quartz mining in several counties during the year, however, and the outlook for increased production in 1913 is encouraging. Mr. Janin discusses separately the gold-dredging industry. Although the copper production of 1912 is little, if any, greater than in 1911, yet no branch of the mineral industry in California shows greater signs of largely increased output, as soon as the smelter fume trouble can be solved in a satisfactory manner. Extensive copper development has been under way for the past two years, particularly in Siskiyou and other northern counties, and large deposits are being systematically developed.

The value of cement produced in 1912 will approximate $10,000,000, being about a million dollars more than in 1911, two and a half millions more than in 1910. This indicates clearly the constantly increasing importance of the cement industry in California, and it is highly probable that the demand for cement will continue and increase in the coming years, together with the expansion of other industries in the state and with increase in population. Structural materials constitute a large part of the mineral output of California. These include bricks, terra-cotta, lime and limestone, marble, sandstone, granite, and other building stones. The development of the state constantly demands an increasingly larger amount of these natural productions, which finds a corresponding increase in the total value of the mineral production.

Thus far, all materials for structural steel and steel rails are brought from outside the state. It is true that a large amount of structural steel is rolled in California mills, but it is all from imported iron or from old metal. It is hoped that before long California may produce all the iron used locally and may also export. There are known to be large and valuable deposits of iron ore in several counties, and the recent success attending the operations at the Heroult electric furnace in Shasta county gives hope that the difficulties have been so far overcome as to permit the manufacture of iron direct from ore in the electric furnace. Detailed estimates of production for the year 1912 were published in the *Mining and Scientific Press*, December 21.

Gold Dredging in California

By Charles Janin

The production from gold dredging in California for the year 1911 was $7,666,461, being $116,000 in excess of the production of 1910. This was somewhat lower than expected, and was caused by the loss of the two large dredges by fire, as mentioned in the review for 1911.* Fig. 1 shows the production of gold won from dredging operations in the principal counties in the state since the beginning of 1898. Yuba county led during 1911, with a production of $2,964,737; Butte was second with $2,251,764; Sacramento came third with $1,805,071. Sacramento county will probably exceed or tie Butte county for second place in 1912. It is a question if the production from dredging in the state has not reached its highest point. Much of the best ground has

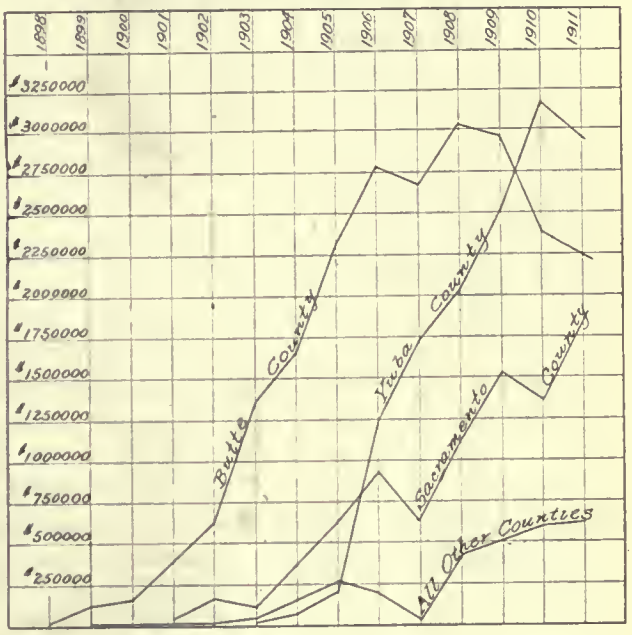


Fig. 1. Growth of gold dredging in California.

been exhausted, and while the larger companies, notably the Natomas and the Yuba Consolidated Gold Fields, may increase the yardage handled, taking into account the lower value of the ground and the exhaustion of the richer areas in Oroville and other districts, the results from operations cannot be expected to increase the total. The production from dredging in Butte county reached its maximum in 1908 with $3,043,051. The production of 1911 shows a decrease of approximately $800,000 below that, and $137,000 below the production of 1910; that for Yuba county also showed a decrease in 1911 as compared to 1910. Figures for 1912 are not yet available. Sacramento county, on account of the increasing yardage being handled, is still increasing its gold production. The combined output from all other counties, while the average value per cubic yard dredged is less than in 1910, shows a slight though steady increase, which will be maintained in 1912 and in 1913 by the addition of proposed new dredges.

There were 64 dredges operating part of the time in 1912 with a total yardage for all dredges of approximately 68,000,000. The average value recovered will be about 11c. per cu. yd. as compared to about 12c. for 1911. The world's record for yardage handled by any dredge is held by Natomas No. 4, a 13-ft. dredge. During 1911, working in unusually favorable ground, this dredge handled 4,056,422 cu. yd. from an average depth of about 19 ft. at a cost of 2.4c. per cu. yd. This will be more appreciated when it is realized that it almost equals the entire yardage handled for the year by the five dredges of Oroville, Ltd. It is not in-

Total—64 dredges operating; 4 under construction; approximate yardage for 1912, 68,000,000.			

[1]Dismantled or out of commission.
[2]Company taken over by O. C. Perry and others.
[3]Under construction.
[4]Being reconstructed with new steel hull.
[5]Total approximate yardage, Shasta, Placer, Trinity, Siskiyou, and Merced counties, 3,000,000.
[6]Formerly suction dredge; reconstructed with Risdon bucket line; sank in November 1912.

tended to use these figures to disparage the latter company, as yardage records and operating costs are in a great measure a result of the physical conditions encountered. A case in point is that of the Hunter dredge, a 5-ft. boat of the Oro Light & Power Co. in Oroville. For a period of three years this dredge successfully handled an average of about 200 cu. yd. per hour. It was moved to a different part of the same property and for some time handled only about 50 cu. yd. per hour, and for a number of months the average has not exceeded 80 cu. yd. per hour. This is similar to the experience of other Oroville dredging companies. Operating costs of dredging at Oroville range from 4 to over 10c. per cu. yd., varying according to the size of the dredge and the character of the ground handled. It is obvious that comparisons of dredging costs cannot properly be made unless operating conditions are similar, and it would be unjust to compare the high operating cost of an Oroville dredge under difficult conditions with that of a dredge in another locality operating under more favorable conditions. Following is a summary of dredging operations for the last three years of the largest dredging companies operating in California:

NATOMAS CONSOLIDATED OF CALIFORNIA

	Year ended December 31—		
	1910.	1911.	1912.
Cubic yards handled...	15,988,362	22,270,586	24,000,000*
Recovery per yd., cents	9.64	9.21	
Cost per yd., cents.....	4.52	3.91	

YUBA CONSOLIDATED GOLD FIELDS.

	Year ended February 28—		
	1910.	1911.	1912.
Cubic yards handled...	13,970,728	15,757,264	15,000,000*
Recovery per yd., cents	20.88	16.86	
Cost per yd., cents.....	5.67	4.67	

OROVILLE DREDGING, LTD.

	Year ended July 31.		Nine months.
	1910.	1911.	1912.
Cubic yards handled...	5,661,612	4,433,262	3,512,842
Recovery per yd., cents	9.91	10.42	10.29
Cost per yd., cents.....	5.05	4.52	5.03

*Approximated.

Yuba County.—There are two dredging companies operating in Yuba county. The Yuba Consolidated Gold Fields, during the year ending February 29, 1912, operated 11 dredges continually and 13 part of the time. No. 2 dredge was dismantled in May, 1911, and No. 1 during 1912. Dredge No. 13 was put in commission in August, 1912, and represented the highest type of dredge construction at the time of building. It has 15-cu. ft. buckets and is the largest dredge in the world to dig 65 ft. below water level. In spite of minor defects and loss of time incident to adjusting new machinery, the dredge averaged nearly 8300 cu. yd. per day at an average operating cost of 3.11c. per cu. yd. The total yardage for all dredges for the year was 15,757,264; the average value was 16.86c. per yard. The dredges turned over 157.46 acres of an average depth of 62.1 ft. The operating cost, exclusive of some special work done by No. 12 for the United States Government was 4.67c. per cu. yd. During 1912 the company shut down dredge No. 1 and contracted with the Yuba Construction Co. for a new 15-ft. dredge, which will be put in commission early in 1913. Yuba No. 10, which was destroyed by fire November 10, 1911, will not be rebuilt; such of the machinery as was saved will be used for repairs on the other dredges. The approximate yardage handled by all dredges of the Yuba Con. Gold Fields for 1912 will be close to 15,000,000.

The Marysville Gold Dredging Co. at Marigold operated two 8½-ft. dredges, which have been described by R. E. Cranston in a previous issue of the *Mining and Scientific Press.* The results of operation are not made public. The total capacity of both dredges is approximately 3,000,000 cu. yd. per year. The plant of the Tarr Mining Co. at Smartsville, which was described in the *Mining and Scientific Press*, October 26, 1911, still remains untried, no work being done during 1912. This plant, which is somewhat allied to dredging, has some interesting features, and its operation is anticipated with interest by engineers who rather doubt whether the management will realize the expected results. A plant of a somewhat similar nature, much less ambitious, is in successful operation at Beauce, Canada. This will be described in a later article.

Butte County.—In Butte county 28 dredges operated part of the time. The total yardage handled would closely approximate 18,500,000. The five dredges of Oroville Dredging, Ltd., handled, for the nine months ended April 30, 1912, 3,512,842 yards of an average value of 10.29c. and an operating cost of 5.03c. This company is also preparing to operate dredges in Colombia. The dredge of the Pennsylvania Dredging Co. finished the company's holdings on the west side of the county road, and is now working on the small piece left on the east side of the road, where it will have about six months' life.

The dredging ground remaining on the east side of the river is fast approaching an end; in about three years more most of the dredges now operating will be out of commission and several companies will finish their ground in less time. Some dredges will doubtless before long be moved to other fields; a number of investigations have been made and options secured on outlying properties. It is generally conceded that any attempts to re-dredge the tailing will be a failure, unless a very low operating cost can be obtained. In general, wherever any of the present dredges have found it necessary to cut through tailing piles in moving, the gold recovered did not pay expenses. With larger dredges, however, where a low operating cost would obtain in land of this character, and in connection with re-soiling arrangements for reclaiming the dredged land, the proposal would seem more attractive and will undoubtedly be tried on some of the areas near Oroville.

The black sand man has again been in evidence in the Oroville district. This summer several attempts were made to treat the black sand or arrange with the dredging companies for that privilege, but, so far as I know, nothing definite was accomplished. The general procedure of those interested in black sand is to express a willingness to experiment with the black sand if the dredging companies will save it for them, and this most of the companies have not found profitable. The efforts of J. H. Leggett, in reclaiming dredged land, have been quite successful. An interesting account of his experiments appears in the *Mining and Scientific Press* of October 26, 1912.

Sacramento County.—There are three dredging companies operating in Sacramento county; two companies each operating one dredge, and the Natomas Consolidated, whose present gold-dredging equipment consists of three dredges in the Oroville field, and nine dredges operating in the Natomas division near Folsom. Three dredges of the latter division are equipped with 12½-ft. buckets, one with 15-ft. buckets, the other dredges have 8 or 9-ft. buckets. Three new dredges were under construction in 1912; No. 10 being put in commission in October. All of these new dredges are of steel construction. No. 10 is equipped with 15-ft. buckets, and, during the first eight days of operation, averaged 15 hours working time, and 3000 yd. per day, or about 200 yd. per hour, while dredging to an average depth of 30 ft. in hard ground containing a number of large boulders. It is said that the dredge has since been digging in excess of 5000 yd. per day. Dredge No. 8, a duplicate of No. 10, replaces the former No. 8, which was destroyed by fire in October, 1911, and will be put in commission in January, 1913. It was originally planned to dismantle No. 4 during 1911, but, on account of the loss of No. 8, this dredge has been kept in commission. No. 7, which will be in operation in April or May, 1913, is equipped with 9-ft. buckets to dig to a depth of 70 ft. It replaces old No. 7, which has worked out all available ground, and uses most of the machinery of the old boat. New No. 7 will be built at Blue Ravine about 7 miles northeast of Natoma on a gravel channel which was worked by drift mining some years ago.

During 1911, the nine old dredges of the Natomas Consolidated averaged 82.4% mining time, as against 77.8% for 1910, and handled 809,310 cu. yd. more material than the same dredges did in 1910. The total yardage handled

for all dredges in 1912 will approximate 24,000,000. In addition to dredging, the Natomas company operates three rock-crushing plants, two at Natomas and one at Oroville, and is also reclaiming a large area of river bottom land north of Sacramento. The rock-crushing plants crushed 538,644 tons of rock, and operated at a profit of $47,459.34 for the year of 1911. Information of the reclamation project, while of interest to holders of Natomas securities, has nothing to do with the review of gold dredging and need not be detailed here.

In addition to Natomas, the Union Dredging Co. on the Fassler ranch at Blue Ravine about 2 miles from Folsom is operating a 9-ft. Bucyrus boat designed to dig 55 ft. below water level. The company owns about 250 acres, some of which is of rather low grade. This dredge was put in commission in March, 1912, and has been working satisfactorily, handling a large yardage. Results of recovery are not available. The Ashburton Mining Co. is operating a 7-ft. dredge which was put in commission in May 1908. The ground averages in depth about 30 ft. and the dredge handles a little under 1,000,000 yd. per year.

UNION No. 1, NEAR FOLSOM; 9-FT. BUCKETS DIGGING 55 FT. BELOW WATER; BUILT BY THE BUCYRUS COMPANY.

NATOMAS No. 8 UNDER CONSTRUCTION; SHOWING ARRANGEMENT OF SCREENS AND GOLD-SAVING TABLES; BUILT BY YUBA CONSTRUCTION COMPANY.

Other Counties.—Of the outside counties, Trinity has attracted most interest during 1912. The Alta Bert dredge, rebuilt by the Union Construction Co., has had a successful season in spite of several weeks' delay on account of bucket-line renewals and repairs, about 30 new buckets replacing some that went to pieces against the hard bedrock. Some of the ground handled averaged 90c. per yard and the clean-up for the year will be in excess of $170,000. The new dredge now obtains power from the Trinity G. M. & R. Co. The Trinity River Dredging Co. started its 9-ft. dredge late in September, but, on account of delays and changes, did not handle much yardage before the end of the year. Details of operations are not available at this writing. The success of the Alta Bert company stimulated prospecting in Trinity county, and a number of areas were drilled during 1912. It is stated that a dredge will be built during 1913 on ground above that of the Trinity River Dredging Company.

In Calaveras county, the Butte dredge operated steadily and successfully during the year. The buckets on this dredge, instead of being of 4-cu. ft. capacity, as ordered by the company, hold only 2.6 cu. ft. by sand measurement, which made considerable difference in yardage and in operating cost. The bucket line will be changed in 1913. In this connection it is interesting to note the difference sometimes existing between rated and actual capacity of dredge buckets; one dredge having so-called 9-ft. buckets was found by measurement to hold 7 cu. ft. of sand. The large dredges with so-called 13 to 16-ft. buckets may hold from 12 cu. ft. upward. In reference to this, the following is pertinent. Last year I asked one of the dredge men at Natomas, the actual size of the buckets on one of the boats. He said: "We always called them 13 cu. ft., but when them mining engineers visited here, they said they were 15-ft. buckets, and we have called them 15 ft. ever since." The Jenny Lind dredge has been operating as usual, and the Calaveras since being re-commissioned.

Dredge Construction.—Pacific No. 1, which sank in December 1911, was repaired and recommissioned in 1912, after being idle about one month. The sinking of the dredge was caused by a leak back of the well-hole, due to the timbers being worn through by gravel dropping from the spill-over at the main dump chute.

El Oro No. 1, which turned over in the dredging pond, was thoroughly overhauled and started digging on March 20. By increasing the deck width 6 ft. on either side, beginning from the curve at the bow and extending to the stern of the boats, the freeboard was increased to 27 inches as compared to about 8 before the accident. The accident was probably caused by the weight of the steel spud, which had been raised preparatory to stepping the dredge ahead, tipping the hull on that side just as the winchman was swinging the boat from the headline from the opposite side. The strain doubtless caused some of the planks to part, and the weight of the water rushing in added to that of the spud, caused the boat to capsize. The hull had just been examined and found to be in fair condition. In fact, a man was emerging from the hatchway when the dredge began to tip, but fortunately he had time to get to a safe position before the dredge sank.

Calaveras 1, which sank in 1911, was also raised, overhauled, and re-commissioned in 1912, and has been doing good work. The Beaver dredge sank on February 21, 1912, but was soon raised and again in operation. It is reported that a good recovery is being made; the ground averages about 14 ft. deep. Leggett No. 4 was taken over by O. C. Perry and R. S. Kettrick and is again in operation. The Yuba Consolidated Gold Fields shut down Yuba No. 1. The Pacific Gold Dredging Co. shut down Pacific No. 2 and 3. The dredge of the United States Gold Dredging Co. on the Sacramento river, above Redding, sank on November 29. This was formerly a suction dredge, which had been converted to a bucket-ladder dredge some years ago by adding a Risdon bucket line. It operated a little during 1912. The total operations of the company have not been great.

Natoma No. 10 commenced operations in October 1912. This is the first dredge of steel construction to be built in

California and represents the highest type of dredge construction in the California fields. The construction of Mokelumne No. 1 was continued during the year, and it will be put in commission in January 1913. This company has been taken over by James H. Goodwin. The dredge is to be equipped with 6-ft. instead of 9-ft. buckets, as contemplated by the old company. The Lawrence Gardella dredge commenced operations in January, on the Downing tract in the Oroville district. This is a 5-ft. boat built by the Union Iron Works and designed to dig 35 ft. below water-level. It is said to be handling about 80,000 yd. per month. The Union dredge near Folsom commenced operations in March 1912. This is a 9-ft. dredge, built by the Bucyrus Co. The Gaylord Mining Co.'s 6-ft. dredge, on Rattlesnake bar, eight miles south of Auburn, was put in commission in April. This dredge was re-designed and rebuilt by the Union Iron Works, partly from the machinery of El Dorado No. 1. The Trinity River Dredging Co. started in September. This is a 9-ft. dredge built by Ed. L. Smith. Some work was done on the hull for the proposed 3½-ft. Treadidgo dredge near Loomis in Placer county, and it is expected that the dredge will be built during 1913. In addition to these dredges, Natomas No. 7 and No. 8 are under construction and will be put in commission early in 1913. No. 8 in January, and No. 7 in April or May.

There are several other dredges proposed for 1913, including one for Trinity county above the Trinity dredge, one for Mammoth bar near Auburn, Placer county, and one for the Merced river north of Snelling, Merced county. The latter is to be a 15-ft. dredge. In addition to this, there are several examinations being made or contemplated of property supposed to be suitable for dredging. This, with the contemplated moving of some Oroville dredges to other areas, indicates that there is still a live interest in gold dredging in the state.

NEVADA

By L. F. Adamson

In the *Mining and Scientific Press* of January 6, 1912, I gave a comparative statement, by quarters, showing the production of precious metals of Nevada for the years 1909-1910 and first six months of 1911. Below are given corresponding figures for the whole of 1911 and first six months of 1912:

	Tons.	Value.
1911.		
First quarter	1,075,139	$ 8,455,543.30
Second quarter	1,073,762	7,917,203.33
Third quarter	1,070,634	7,789,941.07
Fourth quarter	1,001,925	8,264,886.85
Totals	4,221,460	$32,427,574.55
1912.		
First quarter	1,137,460	8,377,502.86
Second quarter	1,280,384	8,994,116.20
Totals	2,417,844	$17,371,619.06

It is hardly expected that the last half of 1912 will show quite as favorably as the first half given above. The reason for this is due largely to two causes. (1) The Goldfield Consolidated Mines Co. is now working on a grade of ore of much less value than through the past two years; (2) the Nevada Consolidated Copper Co. suffered the handicap of a serious labor strike during the month of October, which materially curtailed its production. Despite these conditions, the state as a whole for the year 1912 will show a satisfactory increase in both tonnage and value.

Churchill County.—During quarter ended Sept. 30, 1911, this county produced 4582 tons of ore of a value of $76,555; quarter ended December 31, 14,733 tons, $290,185; quarter ended March 31, 1912, 2461 tons, $66,544, and quarter ended June 30, 15,832 tons, $364,946. The Fairview and Wonder districts particularly, are now in full swing, and the outlook is for a continued heavy production. The falling off during the first quarter of 1912 was due largely to unfavorable weather conditions and temporary shortage of water.

Clark County.—This county produced during last quarter of 1911, 4887 tons, valued at $86,636; first quarter of 1912, 5118 tons, $86,020, and second quarter, 5830 tons, $135,955. An immediate further increase is anticipated. The Yellow Pine Mining Co., of Goodsprings, is largely responsible for this healthy development. Another favorable indication is the recent resumption of operations on the property of the Quartette Mining Co., of Searchlight.

Esmeralda County.—There was produced in this county during first quarter of 1911, 134,503 tons of ore valued at $2,904,827; during the second, 145,831 tons, $2,017,383; third, 149,985 tons, $2,499,034; fourth, 140,184 tons, $2,403,566; during the first quarter of 1912, 133,295 tons, $2,219,538; second quarter, 128,463 tons, $1,783,871. As already intimated, Esmeralda county may reasonably be expected to show a considerable further decrease during last half of 1912, owing particularly to the lower grade of ore worked by the Goldfield Consolidated Mines Co. This company has been a wonderful producer during its short existence, and has paid approximately $24,000,000 in dividends to date. Its mill is still running full capacity but on the lower grade of ore.

Eureka County.—This county produced the fourth quarter of 1911, 21,802 tons, valued at $98,590; during first quarter of 1912, 24,213 tons, $91,097; second quarter, 21,458 tons, $64,280. Eureka county is gradually increasing its tonnage and the values of its ore prospects are bright.

Humboldt County.—Production in Humboldt county during the fourth quarter of 1911 was 1724 tons, value, $306,344; during the first quarter of 1912, 1240 tons, $28,790; and second quarter, 5753 tons, $289,403. This county shows a general average of the highest grade ore produced in the state. It also boasts the greatest number of producers scattered over the broadest field. Perhaps the most interesting district in the county is that in which the National mine is situated. Hard-fought litigation over apex rights was determined this year in favor of the National Mines Co. The mine has yielded over $3,000,000 since 1907.

Lander County.—This county produced during last quarter of 1911, 13,141 tons, value, $48,370; during first quarter of 1912, 57 tons, $7266; second quarter, none. Just at present Lander county's production is somewhat erratic, but development is being quietly pressed and will doubtless lead to a considerable future expansion.

Lincoln County.—During last quarter of 1911, Lincoln county produced 13,391 tons, of a value of $60,568; during the first quarter of 1912, 25,672 tons, worth $226,327; and the second quarter, 14,231 tons, worth $164,190. Lincoln county's outlook is exceptionally bright. The Prince Consolidated Mining Co., and the Day-Bristol Consolidated Mining Co., have both re-entered the list of heavy producers, and the output for the last half of 1912 is confidently expected to show a substantial increase.

Lyon County.—During last quarter of 1911, Lyon county showed a production of 4630 tons, worth $19,927; during the first quarter of 1912, 47,980 tons, $404,890, and the second 72,208 tons, $661,540. The completion of the Wabuska smelter has brought Lyon county to the front in record time, and her copper production is increasing rapidly. The Mason Valley Mines Co. and the Nevada-Douglas Copper Co. will make the output for the last half of 1912 far in advance of that shown for the first half.

Mineral County.—This county showed no production during first three quarters of 1911; during last quarter production showed 1102 tons, of a value of $15,024; no production during first two quarters of 1912. There are many flattering prospects in Mineral county and considerable development work is under way.

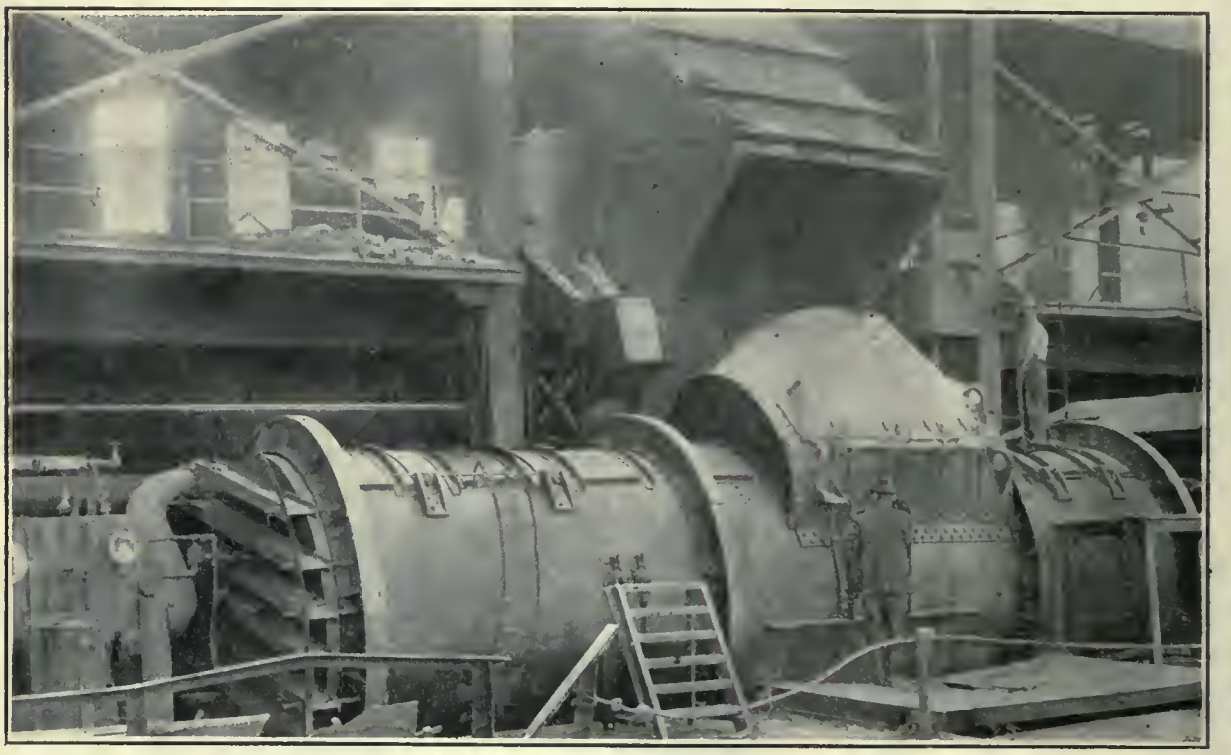
Nye County.—The production in Nye county during first quarter of 1911, shows 247,464 tons valued at $2,527,788; during second quarter, 115,867 tons, $2,324,611; third quarter, 122,204 tons, $2,193,650; fourth quarter, 128,730 tons, $2,310,510; during first quarter of 1912, 124,219 tons, $2,315,530; and second quarter, 127,643 tons, $2,240,884. Nye county is the premier silver-producer of the state, and the gross value of the output is only occasionally exceeded, and by a

very small margin, by the great copper county of White Pine. Nye has a greater number of large tonnage producers than any other county and the outlook was never so bright as at present.

Storey County.—This county produced during first quarter of 1911, 21,230 tons of ore of a value of $175,696; during second quarter, 22,285 tons, $126,195; third quarter, 37,440 tons, $567,594; fourth quarter, 32,419 tons, $443,892; during first quarter of 1912, 27,579 tons, $242,589, and the second, 38,135 tons, $327,183. The old Comstock lode is dependable and may be expected to maintain its present rate of production for some time to come, with a by no means remote possibility of a heavy increase.

Washoe County.—This county produced during the first quarter of 1911, 441 tons of ore valued at $5964; during the second, 182 tons, worth $14,105; during first quarter of 1912, 35 tons, $3350, and second quarter, none. Mining operations in Washoe county have been negligible. Her prospects are the reverse, and when systematic development is begun, the county will doubtless prove a source of considerable production.

White Pine County.—This county produced during first quarter of 1911, 655,178 tons of ore of a value of $2,306,894; during the second, 775,473 tons, $2,019,635; third, 729,157 tons, $2,112,986; fourth quarter, 620,465 tons, $2,150,708; during the first quarter of 1912, 744,470 tons, worth $2,422,705; second quarter, 849,681 tons, $2,959,682. The third quarter of 1912 is expected to show a material increase over preceding quarter. The Giroux Consolidated has now entered the list of heavy producers and every indication points toward increased prosperity in White Pine's already enormous copper industry. Changes at the Nevada Consolidated are discussed separately by Mr. Sorensen.



PIERCE-SMITH CONVERTERS, SHOWING SPECIAL CHARGING DEVICE.

Changes at the Nevada Consolidated

By S. S. Sorensen

Changes in plant and equipment made within 1912 may be summarized as follows:

In the mill 10 Wilfley concentrators, modified as roughing tables, have been placed in No. 1 section together with 4 five-compartment Steptoe classifiers. In sections five and six 4 sets of 36 by 15-in. rolls have been put in for regrinding to do the work done by the Chilean and Huntington mills in the other sections. On the vanner floor 32 Wilfley tables substituted for some of the corrugated belt vanners, and 8 Craven three-decker slimers have been put in. These are treating material which formerly went to tailing. In the line of water recovery 4 Dorr thickeners 17 ft. in diameter by 9 ft. deep have been placed in sections 7 and 8 and similar thickeners are being placed in the other sections.

The pumping equipment has been increased by the addition of a 4-sec.ft. motor-driven, volute pump, which has been installed as an auxiliary to the steam-pumping engine.

The slime-settling plant has been increased by the addition of a string of five ponds excavated along the contour of the hill below the mill, giving a total surface area of nearly two acres. The slime water is taken from the overflow of the existing Steptoe settling tanks and others and is distributed at frequent equal spaces along one side of whatever ponds are in use. The ponds are so arranged that the settled slime can be drawn out and run to a central slime-treatment plant or to a pumping plant to raise it for treatment in the mill. The clean water is pumped back into the mill service by the compound steam pumping engine.

At the smelter pressure-blast air cooling has been extended to all the roasting furnaces by the installation of belt driven fan of 25,000 cu. ft. capacity at a pressure of 3½ in. of water, and the tonnage has been raised to about 90 tons per furnace day with a sulphur elimination of over 60%. No radical change has been made in the construction or working of the reverberatories. The three now running are smelting 440 tons of total charge each per furnace day, with an oil consumption of 0.86 bbl. per ton of charge. One has been rebuilt with an increase in size and a change in the design of binding. The latter has been concentrated into beams set at 5-ft. spaces, centre to centre, instead of the old method of close-set 8 to 12-in. I-beams. This furnace is ready to go into commission whenever required.

At the converters the greatest improvement has been the remodeling of the No. 1 Pierce-Smith basic converter. This converter, which is 30 ft. long inside, and has 46 tuyeres, is making 78 tons of blister per day from 38% matte. Charging is not done through the outlet as hitherto, but through a special charge hole from a fixed launder. A new copper casting machine has been built with oil-fired receiver which holds 50 tons of blister and is tilted by means of gearing from the old disused converters by an electric motor.

UTAH

By Our Special Correspondent

Defeat of the Western Federation of Miners in an important and far-reaching battle; increase in production of staple metals and coal; the development of rare metals, especially uranium and vanadium; these were the leading features of the year 1912 in Utah. The struggle between the mine operators and the Western Federation was perhaps most important. Bingham was the principal battleground, although the conflict waged in other districts. The victory at Bingham settled the question. The operators granted an increase in wages, but fought the recognition of the union. The strike was declared at Bingham September 18, and nearly 5000 men at Bingham, Garfield, and Tooele quit work, affecting the mills and smelters as well as the mines. The principal fight was against the Utah Copper Co. The great weakness of the men lay in the fact that such a large proportion of those employed by the big producers is unskilled. Most of the men who follow the steam-shovel are common laborers, and their places were easily filled. The fight on behalf of the operators was directed by men experienced in breaking strikes. Work was resumed at the mines October 10, under the protection of a large force of deputies, and in a short time there followed a general resumption of operations with nearly a full force of men. There is still a labor shortage, partly due to the fact that so many Greeks and Servians left to fight in the Balkan war. The forces are being steadily recruited, and are now almost up to normal. As a result of this campaign the Western Federation of Miners has lost whatever grip it had at Bingham, while the moral effect at Tintic, Park City, and elsewhere in Utah has been of first importance.

Returns of production for the eleven months, with estimates for December, indicate marked increases. The smelter figures and average values for 1912, compared with the United States Geological Survey statistics for 1911, are as follows:

1912.	Value.
Gold, 230,785 oz., at $20.67	$ 4,770,326
Silver, 14,774,413 oz., at 60.66c	9,759,956
Copper, 145,445,785 lb., at 16.35c	23,780,386
Lead, 155,566,138 lb., at 4.51c	7,016,033
Zinc, 20,303,706 lb., at 6.72c	1,364,409
Total	$46,691,110

1911.	Value.
Gold, 227,217.28 oz.	$ 4,696,998
Silver, 13,473,787 oz.	6,611,107
Copper, 146,960,827 lb.	18,370,103
Lead, 136,496,750 lb.	6,142,354
Zinc, 17,840,261 lb.	1,016,895
Total	$36,837,457

The production of copper would have been still greater had it not been for the Bingham strike. Park City did not come up to the expected mark on zinc, but Tintic more than made up for this deficiency. The high price of spelter, together with the favorable smelting and railway rates, greatly stimulated production. The production of uranium and vanadium began in commercial quantities from the San Rafael swell in the vicinity of Green river in eastern Utah. Two properties have been shipping with comparative regularity while there are a number of prospects. The discovery and initial development of the deposit of alunite near Marysvale was another important event.

At Bingham the Utah Copper Co. attained a record for production, and the decks were cleared for a higher record for 1913. In August the output reached 11,841,162 lb. of copper. The strike came in September, bringing the total for that month down to 6,965,144 lb.; in October it was 2,128,792. The estimated production for November is 4,500,000 lb., and for December, 8,000,000. When working at a maximum capacity, the company has handled as high as 50,000 tons of ore and waste in a day, which is 75% of the amount of material being handled on the Panama canal. During the year 13 sections of the Arthur mill were completed. The mills now have a capacity for concentration of 20,000 tons of ore per day. Officers of the company expect to reach a production of 150,000,000 lb. of copper during 1913. Significant of the closer relations between large producers and consumers of copper was the consolidation of nearly all leading hydro-electric power-plants in Utah. These are now controlled by the Utah Power & Light Co., a $40,000,000 corporation, financed by interests connected with the Utah Copper Co. and the General Electric Co. D. C. Jackling is president. The Utah Consolidated improved during the year, and neighboring properties show increased production. The long tunnel of the Utah Metals Mining Co., extending underneath the Oquirrh range from one side to the other, connecting Bingham with the smelter at Tooele, was not finished as anticipated, but is expected to be completed in the spring of 1913.

Park City has not been the scene of any sensational performances, but the old mines have done well. The Silver King Coalition Mines Co., after accumulating a fund to

MAP OF UTAH.

take care of the heavy judgment obtained against it by the Silver King Consolidated Co., resumed payment of dividends in December. This company and the Daly-Judge have both completed thorough electrical equipment of their properties. The Daly-Judge also resumed dividends and paid $225,000 in 1912. The Daly-Judge has developed enough water-power from the Snake Creek tunnel, in which it is a heavy owner, to meet all of its power requirements. The old Ontario has been the scene of some interesting work on the metallurgy of its silver-gold-lead ores. The Mines Operating Co. has a lease on the property, including the dump. After exhaustive experiments, it was announced that the low-grade ores left in the old stopes and on the dump of the Ontario could be treated to advantage. Concentration and cyanidation were the processes employed at first by the lessees. Further experience demonstrated that the loss of silver through cyanidation of certain classes of the ores was too great. As a result of further experimentation, the company is now treating the ore with a combination of the old chlorination process, concentration, and cyanidation. It is said that a profit is being made on ore averaging $8.67 per ton.

Tintic has had a year of prosperity. Records of shipments show an increase of nearly 20% over 1911, which in turn was the record year for the camp. The Centennial-Eureka still continued in the lead in quantity of ore shipped, with the Iron Blossom second. One of the new properties,

which was brought into the dividend-earning class during the year, was the Chief Consolidated. Such properties as the Yankee, May Day, and others profited by the improved conditions for zinc producers. It is estimated that the zinc production from the Tintic district was close to 8,000,000 lb. in 1912, and that this will be largely increased during 1913 if the spelter market remains strong.

Alta, scene of one of the first mining excitements in Utah, shows signs of revival. The trend during the year has been toward consolidation of properties with a view to economy in operations and to deep drainage. The most important consolidation was that which now operates under the name of the Michigan-Utah Mining Co. This company now owns about 1200 acres of land which it intends to develop at depth. It has solved the transportation problem by means of an overhead tram, with which a projected spur of the Denver & Rio Grande railroad will connect.

Coal development in Utah has had a great impetus through the entry of the United States Smelting, Refining & Mining Co. into the field. This corporation, with an initial investment of approximately $10,000,000, consolidated a number of coal mining companies, and began an extensive campaign of mine development and railroad building. The results will be apparent in 1913.

ARIZONA

BY OUR REGULAR CORRESPONDENT

Copper Mining.—Arizona, already the leading copper producer, is responding to the stimulus of 'high-price' copper in a manner that makes that metal the most interesting factor in the new state's history. The so-called 'disseminated porphyries,' because of their enormous tonnage and the immense concentrating plants required to handle their millions of tons of ore, just now are attracting most attention; and among these the Inspiration Consolidated Copper Co., because of its program of construction, including a 7000-ton mill, is with its neighbors making Miami the present centre of interest. During the past year the Inspiration Copper Co. and the Live Oak Development Co. merged their

MINING GROUPS AT MIAMI.

interests under the name of Inspiration Consolidated Copper Co. From the viewpoint of economy this coalition was deemed necessary. The Miami Copper Co. production for 1912 was about 33,000,000 lb. Its former estimate of 18,000,000 tons of developmed 2.58% ore has been materially increased by recent drillings.

The Ray Consolidated Copper Co. produced about 35,000,000 lb. of copper during 1912 and expects to increase its production to a 70,000,000 lb. basis by 1914. Its 85,000,000 tons of developed 2.2% ore includes the former Ray Central and Hercules, absorbed by the Ray Consolidated last year. The Ray orebody has the distinction of being the third largest, being surpassed only by those of Utah Copper and Chino. Among the low-grade Arizona copper properties now undergoing development, the most promising are the Bagdad Copper Mining Co.'s ground in Yavapai county, the Southwestern Miami in the Miami district, and the claims formerly comprised in the Copper King's holdings at Bisbee. Among the older copper properties the Copper Queen, Calumet & Arizona, Arizona Copper, Old Dominion, Detroit, Shannon, and the United Verde are the great producers, and they have been turning out copper at a steadily increasing rate during the past twelve months and are enlarging their reduction plants. The Copper Queen at Bisbee produced about 82,000,000 lb. last year; the Calumet & Arizona, also in the Warren district, came second with an output of 58,000,000 lb.; the Arizona Copper company's eight mines at Morenci, Metcalf, Longfellow, Garfield, and Coronado turned out more than 36,000,000; the Old Dominion at Globe yielded 27,000,000; the Detroit Copper at Morenci shipped 24,000,000, and the Shannon's contribution from that district was 15,000,000. The gross earnings of the United Verde at Jerome during the past year approximated $5,000,000, although the 1912 dividends were but $6 per share, as compared with $8.25 for 1911. This decrease was due to the increased expense of building a railroad to the site of the 6000-ton smelter now in course of construction, the driving of the Verde adit to tap the ore at the depth of the smelter site in the Verde Valley, and accompanying expenses. The Calumet & Arizona company also is enlarging its smelting plant at Douglas and will handle Shattuck-Arizona ore under a five-year contract. The latter company has about 1,000,000 tons of high-grade ore blocked and when the C. & A. smelter has been completed in July the present daily shipments of 250 tons from that mine will be doubled. Important improvements were made at a number of smelters and all over the state companies operating smaller mines have been building reduction plants.

Gold Mining.—Arizona gold mines have been active during 1912, both as to production and preparatory work. The Commonwealth mine at Pearce is building a $300,000 mill. It will contain thirty 1500-lb. stamps. This mine, in many respects the most remarkable gold and silver producer in the Southwest, has $1,783,000 of low-grade ore blocked. Its rich surface ores have been extracted. The Tom Reed, in Mojave county, during the last months of 1912 produced 120,000 dollars. Its dividends for December amounted to 7% and the board of directors decided that the company could disburse $75,000 in dividends monthly and still maintain the sinking fund. A new orebody has been opened. The cyanidation plant is being perfected and when finished will be one of the best in the United States. The extension of the railroad to the Tennessee mine at Chloride was completed during the past year and shippers from that point will begin this year. Mining activity in the Bradshaw range and adjacent mountains around Prescott has kept pace during the past year with the marked advance in the other parts of the state. The contemplated resumption of work at the Crown Point and Crown King mines is of great interest. The Crown King management last year arranged for the erection of a plant to concentrate ore in old dumps. The mill will be designed to save the zinc as well as the gold. Another interesting utilization of supposedly worthless material is involved in the contract of the United Verde to handle 850,000 tons of Congress tailing. The contract calls for a payment of $1 per ton, but the silicious character of the tailing makes it valuable at the smelter, where the material will be used for converter lining. The gold contents of $1.40 per ton in that way will be recovered. East of Congress the Octavo has been preparing to resume. In Mariposa county the famous Vulture mine, with a record of $16,000,000 production and an estimated additional extraction of $1,000,000 by 'high graders,' is being worked again with a modern mill. The equally historic Harqua Hala gold mine southwest of the Vulture has made preparations to resume work.

Miscellaneous.—During the last three months of 1912 evidence of the presence of oil was discovered in the Verde valley below Jerome. The activity manifested by the Phelps-Dodge, C. & A., Guggenheim Exploration Co., Lewisohns, W. A. Clark, and others in acquiring control of mining prospects throughout Arizona is significant of the development that should mark the present year. Attracted by the wonderfully rich ore in the Superior and Silver King districts the C. & A. and Guggenheim Exploration Co. are engaged

there in active development. The Copper Queen and C. & A. are resuming work at Courtland where the Leadville property was sold for $600,000 in December. The Copper Queen company has also bonded properties in the Patagonia and Big Hat districts. The Magma copper company, producer of the richest copper ore in the state, and the Gibson, which for many years has been the shipper of the world's richest sulphide, maintained a steady output during 1912 and are planning an increase of production for the present year.

NEW MEXICO

During the past year mining in this state was active, especially in Grant and Socorro counties. In the former, the Chino Copper Co. had, at the beginning of the year, two units of its new mill in operation; each treating 1000 tons per day with 70% extraction; three units were added in April and five in September, when 3,549,860 lb. of copper was produced, this being the first time everything worked full time. To the end of November, the output was 25,174,000 lb., that month yielding 4,117,000 lb. of copper, at a cost of about 8c. per pound. Five steam-shovels are working

MAP OF NEW MEXICO.

in the pits of the Hearst and Chino sections of the mine. It is expected that an initial dividend will be paid before long, and production increased.

The Colorado Fuel & Iron Co. is shipping iron ore from its mines at Fierro; while the Phelps-Dodge company erected an electric plant at the Emma copper mine at this place. The Apache Box Canyon shipped a little high-grade ore to the Clear Lake mill, and came in for some comment during the year. Additions were made to the zinc plant of the Chloride Flat company, at Silver City, and ore was shipped to El Paso. At a depth of 30 ft. the Lanamex Mining Co., near Hachita, cut 36 in. of silver-lead ore; the National opened a 4-ft. vein; the Mineral Mountain company started work; and the El Oro has mined good ore. At Pinos Altos, the Utter mine made a shipment of 500 tons of zinc concentrate to Bartlesville, Oklahoma. Shipments of ore were made from the Pacific No. 2 mine, of the Savanna Copper Co. to the smelter at El Paso. The Twin Peaks company is erecting a mill. In Socorro county the Ernestine mine has been operating full time, and now has 30 stamps at work, the mill having been reconstructed, and a power-plant using oil fuel having been completed in the year. In fact, in this district, oil engines of the De La Vergne type, are largely used, and with great satisfaction. Returns from this mine are given in 10-day periods, but the mill has been treating about 3200 tons per month, while the bullion output has been 34,920 oz. and 18 tons of concentrate. The Socorro mines have produced over 5000 tons of ore per month, yielding up to 45,000 oz. of bullion. An extraction of 93% is maintained by concentration and cyanidation. At the mine development is under way on the 600 and 700-ft. levels. The mill is now treating considerable custom ore. The 500-ft. level of the Deadwood mines is opening well, and the mill treats 250 tons per week. During the year the shaft-house and head-frame were burned, and the oil-engine crank-shaft broke. At Kelly the Ozark company is erecting a 200-ton plant, at a cost of $250,000, to treat the lead and zinc ores. The mines have produced largely in the past and seem good for some years yet. The Oaks Co. is developing the Pacific mine, and shipping ore; and the Mogollon company let a lease on the Little Charlie mine to Los Angeles people, the adit yielding high-grade ore. In Lincoln county, the old White Oaks district, 150 miles from El Paso, is having a revival. Coal and water are available near the mines. At the Cat mine a mill is being erected. A suit of interest, involving title to iron mines near Capitan, between the California Industrial Co. of Los Angeles, and the New Mexico M. & M. Co., was decidedly in favor of the former. During the year the Treasure company, in Socorro county, was treating up to 60 tons of ore per day. The ore-bins were burned, but caused little delay. The San Pedro Gold & Copper Co. employs 200 men, and started its smelter in Santa Fe county. It has a 100-ton capacity, and matte is sent to El Paso. At the close of the year low-grade gold deposits supposed to be of unusual size and situated near the border between New Mexico and Colorado were being examined in the interest of Eastern men experienced in mining, and possibly New Mexico will soon become the scene of extensive low-grade gold as well as copper mining.

Reese H. Beddow was appointed State Mine Inspector, this being the first appointment to the position, and new mining regulations have been arranged.

COLORADO

Progress in Colorado during the past year, as perhaps might be expected, has been chiefly along metallurgical lines and is typified by the opening of the state testing plant at the School of Mines at Golden. Largely through the initiative of the president, Victor C. Alderson, an appropriation for the purpose was secured from the state legislature and the plant constructed. The advisory consulting board consists of Philip Argall, D. W. Brunton, Thomas B. Crowe, J. T. Millikin, and W. G. Swart. The plant, which is equipped with full-sized machines and provided with research laboratories, is intended to serve as a testing plant where engineers may treat large lots of ore at minimum expense, as a research laboratory where new methods of treatment for Colorado ores may be sought, and as a working laboratory for the instruction of students. It was discussed at some length in the *Mining and Scientific Press* of December 14 and has aroused great interest throughout the state. The Bureau of Mines has also opened an office and laboratory at Denver, but will probably not construct any large testing works, in order not to conflict with the work of the state plant. It has been urged, and with some reason, that it would be better to have the headquarters of the Bureau of Mines at Golden, but the officials evidently prefer a small laboratory under their own charge for routine work, leaving them free to use the Golden mill in special cases. Early in the year a bill was introduced in Congress providing for establishment of a Bureau of Mines testing plant at Silverton. This did not secure passage. The Silverton people thereupon proceeded to help themselves. Following the successful work of the electrostatic plant of the American Zinc Ore Separating Co. in the Sunnyside mill, which started in March, the construction of a public plant to serve for general customs work and to aid in the metallurgical study of the district was arranged. In the meantime the Iowa-Tiger, Silver Lake, and various other famous mines in this district have produced as usual. At Telluride the Smuggler-Union and Tomboy mills were remodeled during the year under the direction of Gelasio Caetani. The Tomboy mill was de-

scribed in some detail in the *Mining and Scientific Press* of December 28. An essential feature at this mill is the necessity for conserving the water, of which the supply is limited. An attempt was made to increase the rate of settlement in the Dorr thickeners by adding lime. This raised the rate of clear overflow from 70 to 120 gal. per minute, but it was found that the lime interfered so much with amalgamation that its use was discontinued. Pipes take the place of the usual launders in this middling plant, thus eliminating slopping throughout the mill. At the Smuggler-Union the increased zinc content of the ore from the lower levels of the mine made it desirable to remodel the mill in such a way that both zinc ores and those from the upper levels can be treated. The Gilpin county bump tables formerly in use have been replaced by two sets of Wilfley tables, the feed being first classified. The tailing from the tables is re-ground in Hardinge mills and treated on the Triumph vanners previously in use. The tailing goes to the cyanide plant, rebuilt by Walter Read, where the sand tailing separated by Akins classifiers is leached.

MINERAL DISTRICTS OF COLORADO.

The slime is thickened and dewatered on Portland filters, mixed with cyanide solution, agitated in Pachuca tanks, thickened in Dorr thickeners, and filtered. The plant is doing excellent work. At the Liberty Bell mill no changes of note have been made. Deister tables are now in use and are giving satisfactory results. The Suffolk mill of the Ophir company has been rebuilt and minor changes made at other plants. The Camp Bird, which has been near the point of exhaustion for some time, was again revived by a find of ore during the year. In June the resources of the mine were estimated at about $350,000, but since then an additional orebody has been found between the third and fourth levels east below the main adit. This ore averages $25 and is expected to add materially to the value of the property, though even the Camp Bird cannot be expected to last forever. There will be general regret when the old mine 'cashes in.'

At Aspen the Free Silver shaft has been unwatered and through efforts of the Smuggler Leasing Co. and the Hope M. M. & L. Co., the old district is being given a new lease of life. At Leadville the higher prices for the metals reacted favorably on the mines and a gross production of about 60,000 tons per month has been maintained. A new schedule for low-grade zinc ores has been put into effect and carbonate ores containing 22% zinc are now in demand. On the other hand, freight rates to the Kansas smelters have been raised, though not to the extent of interfering with shipments. One of the projects of the year was the formation of a Leadville Mines Pumping Co. to unwater the main downtown district by central pumping. Some such voluntary organization must ultimately be effected unless the state provide, as has been proposed, for the organization of drainage districts in the mining regions.

At Cripple Creek the drainage problem has been temporarily solved by the success of the Roosevelt tunnel. In June 12,000 gal. per minute was being discharged through it and lower ground was rapidly being recovered through the western part of the district. It is estimated that the drainage effected would have cost $3,500,000 in excess of the cost of the work if done by pumping. Plans for connecting with the Vindicator, Golden Cycle, and other mines to the east, are still discussed but nothing definite has yet resulted. Production at Cripple Creek has increased and inroads are being made on the accumulations of low-grade ore in the dumps and stopes. A number of small cyanidation plants are working steadily on oxidized ores. At Stratton's Independence, Philip Argall is treating lump ore at a cost below his estimates, while at the Portland Messrs. Taylor and Crowe continue their good work with the 'Portland process.' An interesting feature of operations at this property is the filling of stopes with sand from the mill. This is not flushed into place but is dewatered and then placed dry by dumping from above. It is expected that the material will pack tight enough to permit work through and next old stopes when, as has often happened in the past, new discoveries make this necessary. In the meantime this use of the tailing minimizes danger from damage suits, already threatening, from the farmers in the valley below. At the Ajax, the new mill is still undergoing adjustment and is being rebuilt so that the announcement of final success must be deferred. Among the big mills at Colorado City the notable event of the year was the final closing of the last chlorination plant, the Standard. The U. S. R. & R. Co. continues to operate its mines at Cripple Creek and is cyaniding accumulated tailing at the mill. The Golden Cycle plant has been operated at capacity as before. An additional Edwards furnace has been placed and numerous ingenious minor improvements have been made. The Portland mill is being rebuilt so as to operate entirely with cyanide, the second unit having been started in May. Merrill presses have been adopted with zinc-dust precipitation. The old cyanide plant originally built to work on tailing has been operating on fresh ore from the mines, but eventually all this is to go through the new presses.

In Clear Creek and Gilpin counties mining matters have gone along with the steady sweep that characterizes the industry in these old standbys. Through the deeper shafts in Gilpin and the Argo or 'Newhouse' tunnel a steady stream of ore has been brought to the surface. The Argo company has progressed to the point of beginning construction of the first unit of the long expected mill at the mouth of the tunnel. This was designed by Arthur Roller and is to be built along the lines of the Hudson mill, including amalgamation, concentration, and cyanidation. A custom mill to treat the ores of the district must necessarily be complex and it has long been proved that no panacea was to be found. In the upper end of the district the Tonopah Mining Co. has a force of men at work examining the Alice mine. This has long been known as a large low-grade deposit. Just how large and whether of present profitable grade will doubtless soon be determined. Rise in price of silver and zinc has helped the mines at Georgetown and Silver Plume and all have been busy.

Legislation regarding the mining industry was not especially important in 1912, though the foundation for far-reaching changes was laid. Influenced by the popular feeling against the 'smelter trust' an amendment to the constitution was adopted declaring reduction plants public utilities. Just what changes this will bring will depend upon future legislation, but the wording of the amendment is so broad as seemingly to include all ore-buyers and custom reduction plants. A much more commendable move was the formation late in the year of a special committee of mining men to recommend to the new Governor and the Legislature changes needed in the mining law. Among others suggested is the enactment of some provision for condemning rights-of-way for power-lines, ditches, and other adjuncts of mining.

WYOMING

By C. E. Jameson

The year 1912 was probably the most prosperous in the history of the mining industry of Wyoming. Increases in the productions of gold and copper were made, while the production of coal and of oil was greater than ever before. Much attention was given the various oilfields during the year, the Salt Creek field, Natrona county, having become important. The production of iron ore, which comes from the Sunrise mine of the C. F. & I. Co., remained the same as in 1911.

The mineral production of the state in 1912 may be estimated as follows:

	Quantity.	Value.
Coal, tons	7,600,000	$13,680,000
Oil, bbl.	2,200,000	1,540,000
Iron ore, tons	1,000,000	1,500,000
Gold, oz.	6,500	130,000
Copper, lb.	150,000	25,500
Silver, oz.	5,400	3,240
Other minerals		2,700,000
Total		$19,578,740

Wide-spread attention was attracted to the Salt Creek oilfield which became a steady producer early in the year. The oil is high in grade while the yield of the wells ranges from 20 to 1200 bbl. per day. Two refineries were erected at Casper in January, having a combined capacity of 6000 bbl., pipe-lines having been laid to the field, 45 miles north, in the preceding year. The refineries have already been doubled and preparations are now being made to again increase their capacity. Fifty-seven wells were drilled during the year, the total number of wells in the field now being 123, of which 102 are productive, 12 have been abandoned, and 9 are drilling. In January one section of land, owned by the state, was leased to the Midwest Oil Co., the royalty rate being 5c. per bbl. Eight wells have been drilled, the first production being made in February, since which time 409,165 bbl. of oil have been produced from this section, while the state has received $20,457 as royalties.* At no time has the entire production been taken, as the refineries are not capable of handling the output of the field. In March the output of one well was handled separately in order to gauge it. The yield of this one well for the month was 29,357 bbl., or an average of 947 per day. The production of which the field is capable is more than 12,000 bbl., though not more than 7500 per day is produced at present. Production of petroleum from the Lander district was somewhat less than in the preceding year. The Wyopo Oil Co., the principal producer, went into the hands of a receiver early in the year, and although some work was carried on in the reservation fields, it was of a desultory character. Production from the Spring Valley and Byron fields remained about stationary. Oil is reported to have been obtained in a well drilled near Cody, but no production has yet been made. Near Moorcroft 7 wells have been drilled and oil, chiefly valuable for lubricating purposes, was obtained. This field will probably be a producer in the spring. Several wells have been drilled near Sundance and, although oil was obtained, the results were not altogether satisfactory. No production was made from the Douglas field. One well was drilled near Glenrock and oil with an asphaltum base, 11.6° Beaume, was obtained. The production of the state for the year is estimated to be 2,200,000 bbl., valued at $1,540,000, an increase of $1,155,000 in value and 1,925,000 bbl. in quantity over the preceding year.

Mining was active in the South Pass gold district and a find of high-grade ore was made near Lewiston. Fifteen tons of ore shipped to Denver netted $700 per ton. The Beck company kept its stamp-mill in operation throughout the year and erected a 50-ton cyanidation plant. The XL Dredging Co. commenced hydraulicking in the spring but, on account of the shortage of water, operated only one monitor. Stamp-mills are now being erected by the Hidden Hand and the Mary Ellen companies. In the Medicine Bow district the Victoria company carried on development during the summer and has opened a rather large body of ore reported to contain $9 per ton in gold. A stamp-mill was erected in the Bear Lodge district, Crook county, but no ore has been milled.

The affairs of the Penn-Wyoming Copper Co. continued to be in litigation, and the smelter owned by the company was idle. But little work was done in the Encampment district. Shipments of copper ore were made from the Esterbrook and Hartville districts. A number of cars of ore shipped from Hartville gave net returns of $20 per ton. No production of asbestos was made from the Casper Mountain district, though the International Asbestos Co. reports a large tonnage of ore ready for fiberizing. The Colorado Fuel & Iron Co. operated its iron mines at Sunrise throughout the year, mining about 3000 tons of ore per day.

*Figures for December are not included.

IDAHO

The estimated operating profits of some of the principal mines of Idaho for 1912, as compared with the preceding year, are as follows:

	1912.	1911.
Bunker Hill	$752,100	$866,550
Federal	720,000	840,000
Hercules	600,000	400,000
Hecla	300,000	240,000
Success	180,000	60,000
Snowstorm	75,000	.....

Results at the Snowstorm are only based on a comparatively few months of work, as the first unit of the 200-ton mill was started about the middle of the year and the second unit during the autumn. The leaching plant is no longer in use. This is a copper mine, the only one of importance in Idaho, as the Lost Packer did not operate during the year. The operating profit at the Hercules is only estimated, as it is not a stock company. The mill has a capacity of 400 tons per day and is unusual in that it consists of two adjacent buildings, the pulp from the Hancock and Harz jig tailing being crushed in Huntington mills and pumped to the top of the other building, where it is dewatered, classified, and treated on Franz tables and Frue vanners. The Federal company operated its three mills, the success of the McQuisten tube plant for treating the tailing from the Wilfley tables being the matter of most interest. The first unit of this plant did such good work that a second was added, starting in July and making 248 tubes in all. The capacity is now 200 tons per day. The feed to the plant contains about 10% Zn, and about one-half of it is separated as a concentrate containing 48% Zn, at a total cost for operation and maintenance of not over 50c. per ton, yielding a good profit on the operation. During the year the Federal company bought the Wilson-Mackay property and is now negotiating for the control of the Star, adjoining the Morning at Mullan.

Early in the spring the Bunker Hill & Sullivan started the second unit of its new mill, constructed by R. S. Handy following the general design of the first unit constructed by Gelasio Caetani two years ago, but embodying important improvements worked out in practice in the interval. The old mill is now being remodeled to form a third unit. The Bunker Hill, Federal, and other companies engaged in milling, combined in the purchase of lands along the Coeur d'Alene river where damage from tailing was alleged and suits were threatened. The Gold Hunter mill has been increased to 400 tons per day and the 50-ton mill of the Black Horse was started during the year. The Success, which has a 250-ton mill in Nine-Mile canyon is shipping a 42% Zn concentrate and an 80% extraction is reported. The operating profit was considerably increased during the year. Work in the Carter district has been stimulated by the introduction of electric power, brought in from Thompsons Falls by the Iron Mountain company. The 150-ton mill of the Wilbert Mines Co., 25 miles north of Arco, was started during the spring and has been shipping silver-lead concen-

trate, making an 80% extraction. The dredging work in the Boise basin was described in some detail by J. H. Miles in the *Mining and Scientific Press* of September 14, page 330. The Boston Idaho G. D. Co., operating a 5-ft. Union-Risdon boat in November, handled 99,560 cu. yd. and had a running time of 82.6%, an unusually good record. There is little of interest to add regarding placer and gold-quartz milling. Serious efforts are being made to establish a state geological survey, and hopes of success are entertained. The year in the Coeur d'Alene was marred by much litigation, some of which has been settled, but much of which is still in progress, so that the year closes somewhat under a cloud.

OKLAHOMA

In common with other Middle Western states the mineral industry of Oklahoma enjoyed a prosperous year. The zinc mines near Miami in the northeast benefited from the high prices prevailing, and the smelters at Bartlesville, which still enjoy the benefits of natural gas fuel, have been growing as those in Kansas were dismantled. The coal

OKLAHOMA MINERAL DISTRICTS.

mines have had an eager market to meet and the demand for petroleum has been such that stocks have decreased despite a slight increase in production. Figures showing runs and stocks in the mid-continental field, including Kansas and Oklahoma, as compiled monthly by *The Oil and Gas Journal*, are presented below:

1911.	Runs, bbl.	Stocks, bbl.
December	4,087,224	50,260,203
1912.		
January	3,857,448	49,876,465
February	3,719,798	49,607,961
March	3,826.496	49,371,119
April	3,671,572	49,022,689
May	4,171,483	49,022,614
June	4,162,648	48,752,055
July	4,468,873	48,865,091
August	4,703,036	48,751,731
September	4,482,978	48,301,432
October	4,896,647	48,093,614
November	4,790,734	47,794,788

TEXAS

While no startling changes occurred in the year, the Texas mineral industry is in healthy condition. At the Shafter silver mine production has continued as usual, but improvements in practice have been introduced. The most important was the substitution of a De La Vergne gas-engine for the steam-engine that has long served so well. In the *Mining and Scientific Press* of December 14, W. S. Noyes gave figures showing that with Texas crude oil for fuel, only 0.425 lb. per brake-horse-power was now used, as against 2.882 with the Corliss engine. Property adjacent to the Shafter has been bonded by the Lewisohns and is being tested under direction of Louis A. Wright. If this venture results in discovery of as good a mine as that owned by the Presidio M. Co., the newcomers will be fortunate. The tin mines near El Paso made no shipment in 1912, development being inadequate to support the plant erected. Conditions in the quicksilver district are discussed on another page by Mr. Dennis. Iron mining in northeastern Texas is developing, and despite the low grade of the ore seems destined to become important. One feature of the year was the commencing of production from the sulphur deposits near Freeport on the coast. The work is undertaken by the 'Swenson Syndicate,' which includes such well known men as James Stillman, J. H. Hammond, and A. C. Beatty. Attention to the sulphur possibilities of this section was attracted a few years ago when several wells that were bored in search of oil upon Bryan Heights, a natural mound situated nearby and about three miles from the Gulf of Mexico, penetrated, at a depth of 700 to 900 ft., a deposit of sulphur. The Swenson Syndicate acquired the land and began systematic testing of the extent of the bed. A number of wells were bored, thoroughly exploring all parts of the mound. The mound is 15 to 20 ft. higher than the surrounding plain and embraces about 1000 acres. No estimates of the amount of sulphur available have been published. It is understood that mining will be attempted by a process similar to that used by the Union Sulphur Co., in Louisiana, and the probable contest with that concern attracts much quiet interest. The Swenson Syndicate is reputed to own oil lands near Tampico, Mexico, and to contemplate importing its fuel from that source. The petroleum industry of Texas and Louisiana has been characterized for the year by extensive wild-catting, but no striking discoveries were made. Production amounts to about 18,000 to 19,000 bbl. per day in Texas and 6000 to 8000 for Louisiana.

ILLINOIS

The mineral industry in Illinois was generally prosperous in 1912. The coal mines were active, and for the first time in several years operators made money. Important changes in the industry are discussed elsewhere. In the oilfields the important feature of the year was the decrease in production. The runs and stocks for the first ten months of the year and for 1911, as recorded by the Ohio Oil Co., are given below. To get total production, approximately 100,000 bbl. per month must be added to the runs to cover oil handled by the Tidewater Oil Company.

1911.	Runs, bbl.	Stocks, bbl.
January	2,160,878.48	26,243,014.70
February	1,994,231.42	25,635,245.01
March	2,589,635.00	23,997,496.00
April	2,173,939.00	24,005,009.96
May	2,209,881.16	24,129,387.96
June	2,208,358.29	23,195,749.12
July	2,292,926.66	22,714,182.54
August	2,340,877.21	22,265,927.92
September	2,179,591.49	21,904,718.65
October	2,195,407.56	21,359,482.42
1912.		
January	1,879,413.30	18,393,303.04
February	1,872,169.87	17,706,834.72
March	1,970,421.14	17,278,537.27
April	1,935,015.12	17,001,287.72
May	2,104,689.43	16,636,328.76
June	2,099,719.88	16,235,352.83
July	2,241,787.12	15,689,993.67
August	2,013,419.46	14,682,822.79
September	1,885,225.99	13,949,064.15
October	1,915,926.31	13,039,507.24

Test wells sunk to the Trenton horizon offer some encouragement, and plans are being perfected for serious exploration of the lower sands. A few small fields have been found in the southern and western part of the state, but as yet nothing comparable to the Clarke-Laurence county fields has been found. The fluorspar mines in the south, and the lead-zinc mines in the north increased production. The output of the zinc mines at Galena amounts now to about 1000 tons per month, mainly of low-grade ore. Important additions were made to various zinc smelters, as described elsewhere by Mr. Hall.

MICHIGAN COPPER MINES

By Robert H. Maurer

As nearly as can be calculated at this time, the output of the Lake Superior copper mines for the year 1912 approximates 219,703,000 lb. of fine copper, as compared with 218,185,235 in 1911. This output, representing a gross value of nearly $40,000,000, was made at a cost of about $22,000,000, or at approximately 10c. per pound for all companies. Approximately 8,000,000 lb. of copper, about 4% of the total, was produced at a loss, this production being the output of companies that are still in the development stage. Omitting this production and considering only the output of the profitable producers, the average cost was about 9.5c. per pound.

Twenty companies contributed to the output for 1912, as compared with 22 in the preceding year, and there are now 19 companies yielding a regular production with a combined output not far from 22,000,000 lb. fine copper annually. There is little likelihood that the present rate of production will materially increase in the next year or two, though a 5% increase is easily possible. New sources of production in the present year, 1913, are seemingly limited to the Hancock mine, the Ojibway, and the La Salle, and will show no marked effect on the annual rate for a year at least. These companies, producing in a small way, yielded a combined output of 1,049,622 lb. in the years 1911 and 1912. Any material increase must come from one or several of the present producers. There is no undue restriction on output, though production would be materially greater were labor conditions more favorable. A number of companies, notably Calumet & Hecla and Osceola, are capable of far greater production. A number of others are gradually increasing their outputs, and all are producing well up to capacity. Where production has materially declined, the cause may be found in the physical conditions of the mine.

A table showing the estimated production in pounds of fine copper of the several Lake Superior companies for the year 1912, and also figures of production for the preceding year, is appended herewith. Official figures will not be available in some instances for several months to come.

Company.	1912.	1911.
Calumet & Hecla	69,197,646	74,130,977
Quincy	20,972,000	22,252,943
Osceola	18,092,925	18,388,193
Champion	16,495,200	15,639,426
Ahmeek	16,368,955	15,196,127
Baltic	13,572,800	15,370,449
Mohawk	12,058,000	12,091,056
Wolverine	9,160,000	9,408,960
Isle Royale	8,096,291	7,090,120
Tamarack	7,670,704	7,494,070
Trimountain	7,288,800	6,120,417
Allouez	5,474,780	4,780,494
Superior	3,881,709	3,326,233
Winona	2,500,000	1,275,675
Mass	2,350,000	1,326,898
Franklin	1,970,755	820,203
Centennial	1,640,435	1,493,834
Lake	1,500,000	318,050
Victoria	1,452,000	1,303,331
Miscellaneous	20,000	1,049,622
Total	219,703,000	218,877,078

The product in 1912 commanded unusually high prices, the average being around 16½c. per lb. This has been exceeded only twice in the past decade, the average price in 1906 being 19.6c., and 20c. in 1907. The average for the decade was 15.12c. The market price, which in the preceding year held steadily around 12½c., advanced sharply just before the close, and in the beginning of 1912 stood at 14.33c. It reached its highest at 17.69c. in September and was holding firm at 17.5c. at the close of the year. The average, which is figured at 16.55c., compares with an average price of 12.63c. recorded in the preceding year. Dividends for the year amounted to $9,069,257, making a grand total to date of $200,030,418. Calumet & Hecla led for the year with $4,200,000, as it does in the totals with $119,100,000. The second heaviest dividend-payer in 1912 was Osceola, which disbursed $1,201,875, making a total of $11,266,250.

MINNESOTA

The year was a prosperous one on the iron ranges. General conditions in the iron trade are discussed on another page, but below are given the latest figures from the various railroad docks, covering iron-ore shipments by lake. Though

STEAM-SHOVEL STRIPPING A MINNESOTA IRON MINE.

these may be changed by a few thousand tons, they are substantially accurate as a final total:

	1912. Gross tons.
Duluth, Missabe & Northern (Duluth)	10,505,577
Duluth & Iron Range (Two Harbors)	9,370,970
Great Northern (Superior)	13,936,899
Soo Line (Superior)	305,000
Lake Superior & Ishpeming (Marquette)	2,224,217
Duluth, South Shore & Atlantic (Marquette)	1,054,085
Chicago & Northwestern (Ashland)	3,776,500
Soo Line (Ashland)	1,018,788
Chicago & Northwestern (Escanaba)	4,050,190
Chicago, Milwaukee & St. Paul (Escanaba)	1,202,600
Total	47,444,826

To this must be added whatever all-rail shipments are made direct to furnaces, which may be heavier than usual. Docks are left unusually clean of ore; the lake season ceased during good weather and did not drag on in freezing cold, as is sometimes the case. The fall has been especially favorable for traffic, which continued in great volume to the very last.

WISCONSIN ZINC MINES

By W. F. Boericke

The year 1912 has been a prosperous one for the Wisconsin zinc district. The fact contributing most largely thereto has been the highly satisfactory price of zinc ore, and the steady and uniform demand for all grades, especially during the past six months. This has enabled the larger companies to mine their low-grade ores at a profit, has increased the ore reserves to a marked extent, and has rendered profitable thousands of tons of material. New companies have come into the field, attracted by the high prices and many of the old mines have been re-opened. The business of mining has been conducted generally on a solid foundation, with no press agent work, and almost entirely by private companies or individuals.

Speaking generally, the year has seen a steady growth of the larger companies in the holdings and scale of operations. There are still a considerable number of mines worked in a small way by lesees, but the number is decreasing. Much of the desirable zinc land is now held by the large operators, who have no intention of leasing. The crude methods of mining formerly in vogue are disappearing, and there is no question but that average costs

for the year in the majority of cases have been substantially reduced. The most serious handicap with which the district has had to contend has been a shortage of labor. Shovelers and drillmen are in demand at nearly every mine, and the winter supply usually confidently counted on has not been forthcoming. Electric power has replaced steam in many of the mines, the Interstate Light & Power Co. of Galena supplying the Hazel Green, Benton, and Platteville fields, while the Mineral Point Power Co. has just completed a power line to Mifflin and Livingston.

Highland.—This field produces by far the largest amount of zinc carbonate locally known as 'drybone' in the district and has had a good year. A large proportion of the 'bone' is mined by lessees, working above the water-level. The best of the ore at this horizon has been mined, but the field is a large one and no doubt further prospecting will show other easily won deposits. The Franklin has shipped largely to the oxide works at Mineral Point. The Kennedy and Wallace have also shipped. The Red Jacket mine has been bought by the Mineral Point Zinc Co., which is heavily interested in the Highland field, and will probably be operated next year. There has been considerable prospection for blende in the formation below the carbonate, with generally encouraging results.

WISCONSIN ZINC MINES IN RELATION TO SMELTERS AND FUEL.

Linden.—The production at this place has been about the same as last year, and there has not been much prospecting. The shipping mines include the Glanville, Optimo, Hinkle, Ross, and the Morrison. The Rajah mine was closed.

Mifflin.—The Peacock mine, for some time conducted at a loss, is now showing a handsome profit. The Squirrel and the Dodger, on the same range presumably, have made a considerable tonnage of high-grade concentrates. The Slack mine has been closed.

Livingston.—The Coker has increased its production largely, and ranks among the big mines of the district. Over 10,000 tons per month is mined. A new double-compartment shaft is being equipped for two cages, an innovation in the district. At present hoisting is being done from three shafts. It is probable that a new mill will be built on another part of the property. The Ellsworth, controlled by the Vinegar Hill Zinc Co., is mining on the Sunrise land.

Platteville.—The Empire, one of the largest mines of the district, is now controlled by the Wisconsin Zinc Co. The mine is in excellent shape, and producing heavily. All the Platteville mines are working full shifts, and the new discoveries on the East End and Klar-Piquette have given an impetus to this field. The East End is reported to have made one of the best discoveries of the year. The Grant County mine has been reopened by the Vinegar Hill Zinc Company.

Cuba City.—The Wilkinson, controlled by the Vinegar Hill Zinc Co., is successfully working some of the lowest-grade ore in the district. The Board of Trade, formerly a heavy lead producer, has been closed. The Baxter has been reopened by the Frontier Mining Co. There is considerable drilling going on in the field, and it is likely to be active in 1913.

Benton and New Diggings.—The Frontier, another of the big mines, besides maintaining its heavy production, has opened a shaft on the Hird fraction. The old Jack of Clubs is now being worked by the Lafayette Mining Co., with a new equipment. The Fields mine at New Diggings is probably the premier of the district, having made a monthly production of 1000 tons of 58% concentrate. The Fox mine, owned by the Mineral Point Zinc Co., has worked steadily throughout the year, on a north and south run, now proved for over half a mile.

Hazel Green.—The Unity has been closed down. The Vinegar Hill, Kennedy, Northwestern, Illinois, Roliy, and Cleveland have all worked steadily and made a heavy production. The Kennedy mine looks especially well. This mine includes the old Winnebago, or Hoskins. The Cleveland Mining Co. lately acquired the Scrabble Creek and will build a mill. The Badger is building a mill on the Big Dad ground. The Mills mine has been closed during the winter. This part of the district has been particularly hard hit by lack of men.

Galena.—The Mineral Point Zinc Co. has had a small force of men prospecting the old Ryan farm, which was a heavy lead producer in early days. The results of the work will be of interest to all in proving this part of the field, which has never been thoroughly tested, and may result in enlarging the present lines materially. The same company has brought the old Black Jack mine south of Galena, and will immediately equip it for a heavy production. The Vinegar Hill mine, north of Galena and near the state border, is still actively worked by the company which, beginning at this property, has expanded its operations throughout the district.

MISSOURI

High prices and unusual activity were characteristic of the year among the mines of Missouri. Lead mining, the pioneer industry of the state, was especially prosperous. While final figures are not at hand, it is probable that the production in 1912 exceeded that of the record year 1910, when it amounted to 161,016 tons of pig lead. Missouri now produces nearly two-thirds of the crude ore, and but little less than half of the total of the pig lead of the United States. The bulk of the production comes from the disseminated lead region of the southeast. The output is now mainly from St. Francois country; the famous old Mine La Motte, the Catherine, and the North American mines in Madison county being all involved in financial difficulties and temporarily out of the running. The territory to the west in Washington county, where disseminated ore is thought to exist at depth, still awaits serious prospecting. The expense of deep drilling through the overlying cherty limestone has so far prevented thorough exploration. In St. Francois county there are five principal companies. The Federal Lead Co., a Guggenheim concern; the St. Joseph Lead Co., and the Doe Run Lead Co., two sister concerns controlled by the Jones, Parsons, and Camp families; the St. Louis Smelting & Refining Co., controlled by the National Lead Co.; the Desloge Lead Co., controlled by the Desloge family. Each of the first three named mine approximately a million tons of ore per year, while the last two together produce another million tons. Some notion of the scale of operations may be gained from the fact that the new Federal mill handles 4500 tons per day and the Doe Run No. 3, now crushing 65,000 tons per month, is being doubled in capacity. Ore containing an average of but 2% lead is being treated by one company and it is to be remembered that lead is practically the only metal of value in the ore. While the concentrates contain an average of one ounce of silver per ton, the metal is only de-silverized at one plant. At the Federal, H. A. Guess, the capable manager, saves a small amount of zincy iron-copper concentrate. This has been re-treated in a magnetic separation plant and small shipments of copper ore have been made for some time. Temporarily the zinc product has been stored but ultimately it, too, will be made to swell the profits. The cost of mining and milling, because of the simple character of the ore, the large scale of operations, freedom from timber expense, and low cost of fuel, has been brought down to low figures. Roughly, the mining costs 80c. per ton and milling 20 to 30c. With legitimate overhead and selling expense ore can be handled in this district at a total cost of $1.25 per ton and as a matter of fact, all the companies are making excellent profits.

Dissatisfaction among minority stockholders in the St. Joseph and Doe Run companies was voiced at the annual meeting by Robert Holmes of St. Louis and has led to action in the New York courts since. No criticism of the technical work has been made, though the policy of continuing to operate the old Doe Run mill, finally closed last fall, was questioned. O. M. Bilharz, who has charge as engineer of the mines and mills of the companies, is credited with having done excellent work. D. A. Jones, president of the companies, points out to stockholders that the Doe Run, since its organization in 1866, has increased its holdings from 100 to 7057 acres. In the past year 932,220 tons of ore has been hoisted, yielding 53,080 tons of concentrate and 33,729 of metallic lead, worth $2,267,155. All expenses, including operation and interest, amounted to $1,687,167. The approximate net profit was $576,988. A 3% dividend was paid in place of the usual 6. It is estimated that next year, due to economies and enlargement of No. 3 mill, the net income will be doubled. Because of an active campaign of land buying it became necessary a year ago to issue $2,000,000 worth of bonds. As representing the bond-holders, Philip N. Moore was made a director and consulting engineer for the Doe Run company last year. A part of the bonds have already been retired and no one doubts the soundness of the two companies though probably some economies in the New York office may be effected. The National and Desloge companies have had a prosperous year and are doing excellent work.

Zinc, in the production of which Missouri also leads, enjoyed unusually high prices in 1912 and as one result a record production was made. On p. 31 of this issue will be found a detailed statement of shipments and prices. The year has been marked by the re-opening of many old mines at Joplin and many improvements in practice. Entry of the large companies, notably the American Smelters Securities, into the field will undoubtedly result in material changes in methods. The average zinc content of Missouri ores is given by C. E. Siebenthal of the U. S. Geological Survey, as 1.5%, which means a value in the ground of $1.80 to $2.10 per ton. Allowing for the inevitable metallurgical losses, it will be seen that Missouri zinc mining must needs be conducted with great care to assure any profit.

In 1911 the state produced silver to the value of $26,430 and copper worth $80,051. Both these items will show an increase in 1912, since both are in part related to lead production. In addition copper is mined separately at a number of points in periods of high prices. At the close of the year the St. Genevieve and the Sullivan copper mines, in particular, were being reopened. Iron mining continues, but is not extensive. Within the year the state Bureau of Geology and Mines distributed an excellent report upon the iron deposits. Coal mining and the quarry industries enjoyed their share of the industrial prosperity now dawning in the Middle West.

SOUTH DAKOTA

By Jesse Simmons

Gold production from South Dakota in 1912 broke the record. The best previous year was 1911, when $7,636,555 was turned out. Over 90% of the gold production of South Dakota comes from Lawrence county, where are the Homestake, Wasp No. 2, Trojan, Golden Reward, Mogul, and other large mines. Mining is confined to the Black Hills. The remainder of the state is farming country; many counties lacking even deposits of stone suitable for foundation rock. The Black Hills has been a producer of gold for 37 years, commencing with $1,200,000 in 1876 and gradually increasing nearly every year, until the present. The total production of gold in the district according to the United States Geological Survey, was $162,940,149 up to and including 1911. It is safe to say that the next period of 37 years will show a far greater output than the past.

The Homestake, at Lead, is the world's greatest gold mine. This is said advisedly. It has paid the greatest number of consecutive dividends, has the greatest quantity of ore blocked out, and on the immense scale of operations makes the best recovery at the lowest cost. It has paid dividends since 1877, with only two interruptions, once when a fire in the mine and another time when labor difficulties caused a suspension. The mine today contains an ore supply sufficient for the present scale of operations for 20 years. The six mills with 1000 stamps handle a little more than 4175 tons per day. The average yield is a little better than $4 per ton, and only slightly in excess of 5% of the gross value is lost in the tailing, the treatment of amalgamation, sand leaching, and slime treatment in Merrill presses, yielding nearly 95% of the gold. The year 1912 was the most prosperous in the experience of the Homestake, and in recognition of the loyalty of the workmen, the company in November announced that it would pay to each employee who was with the company during the year and employed in December, a check equal to 7% of his earnings for the year. This is a bonus, and the success of future operations will determine whether it shall be annually distributed. Another gratuity to the employees is the construction of Recreation Hall, equipped with reading rooms, baths, billiard rooms, bowling alleys, and an opera house seating 1000. This will be completed at an estimated cost of $200,000. Its privileges will be free to employees of the company. A meeting of stockholders will be held in San Francisco in February when a proposal to increase the capital stock will be voted upon. It is planned to declare a stock dividend of 15%. The payment of such a dividend will require the issuance of 32,760 shares of stock, making the total 251,160 shares. To pay the usual

monthly dividend of 50c. per share $125,580 will be required, an increase of $16,380, or $196,560 per year—practically the same amount as will be called for by the payment of the 7% bonus to the employees. The most important improvement of the year was the completion of the Spearfish hydro-electric plant. This plant has been in operation since summer, and all of the stamps and rock crushers are now driven by the electric power generated here and at the Englewood plant. Further applications of electric power are to be made, and within a few months the entire 5450 available horse-power will be in use. The introduction of this power saves at least $40 per horse-power per year over the cost of operating steam-engines in the various mills.

The Wasp No. 2 had a prosperous year—the best in its history. The mine paid $85,000 in dividends, making a total of $381,965 to date. The property was operated steadily throughout the year at the maximum capacity of the mill, 15,000 tons per month, excepting 40 days in January and February when bad weather interfered. Only the ordinary improvements and repairs were made during the year. The steam-shovel was used to advantage for the first full season, and made a decided reduction in stripping costs. This is the banner low-grade mine of the world, the total cost of mining and milling running $1.25 per ton. The net bullion recovery is under $2 per ton.

The Golden Reward is just putting the finishing touches on a roasting plant of 75 tons daily capacity, built to give the ores of the Astoria mine a preliminary roast before they are sent to Deadwood for treatment in the company's cyanide mill. The plant will also be used for experimentation on the so-called 'blue ores' of the Bald Mountain district as it is believed that roasting will make them amenable to cyanidation. The plant is constructed on the unit plan, and at little expense it can be doubled in size should its operation prove successful. The Wedge furnace is used and Wyoming oil will be the fuel. The plant was erected at the Astoria mine, where late developments have exposed a body of ore containing over 200,000 tons, with the limits not yet defined. This ore roasts easily and then makes an almost perfect cyanidation material. The mill at Deadwood was operated steadily.

The Trojan company operated steadily, handling about 200 tons per day in the cyanide mill. A number of improvements were made, the most important of which was the opening and equipment of the Portland mine with air-compressor and electric hoist, the building of several thousand feet of tramway, and the erection of a complete machine shop. Plans for the present year include the doubling of the mill capacity. This can be done by adding tanks and slime treatment, the crushing and grinding departments being ample for the increased tonnage.

In March the mill of the Mogul company, at Pluma, was destroyed by fire, and was not rebuilt. The balance of the year a small daily tonnage, largely from the Lucile mine, was shipped to the Lundberg, Dorr & Wilson mill, at Terry. The insurance on the burned plant is in the hands of trustees, and this fund, with what machinery can be utilized from the old mill, will be sufficient to provide the company with a good plant. This, it is stated, will likely be erected near the mine, perhaps at or near the Snowstorm property, in Nevada gulch. Lundberg, Dorr & Wilson confined the operation of their plant at Terry largely to the treatment of custom ores, although some rock from the Buxton and Big Bonanza mines, belonging to them, was treated. The mill operated steadily through the year.

The Victoria, in the Spearfish canyon district, and the Black Hills Standard, at Ragged Top, made small productions, but each promises to yield more the present year. The New Reliance mill was equipped with four Dorr thickeners and a Portland filter, and after a suspension of several months, while this machinery was being placed and other necessary changes made, is now in operation. It is stated that the continuous decantation process is proving more satisfactory than any previous method attempted for treating slime at this mill. The mill crushes about 100 tons daily, 30 stamps being employed. The Richmond mine, at Galena, was a steady producer of small quantities of silver-lead ores, shipped to the Omaha smelter. The Monarch mine, in Two Bit gulch, produced good grade smelting ores, as did a number of properties in the Bald Mountain district. The Forest City mine, at Hill City, erected a 5-stamp mill and is operating continuously. The Golden Summit produced several thousand dollars' worth of high-grade free-gold ore, much of it specimen rock. The Bismarck company, which owns a property adjoining the Wasp No. 2, has practically completed a 300-ton mill, which will shortly be in operation.

The Black Hills Smelting Co., at Galena, has completed a 150-ton smelter, and will blow it in early this year. Title to the Golden Crest was to be adjusted soon, and there was every indication that before the end of the year the mill would be in steady operation. Among the development projects one of the most important finds was that in the Gilt Edge mine, at Galena, where a body of heavy pyrite was found, which it is proposed to ship to the smelter in quantities of about 25 tons per day when the plant is started. The North Homestake, at Maitland, completed the shaft to the 620-ft. level and did several hundred feet of cross-cutting. The Gold King company was organized and started development on a property at Rochford, that at the present time is showing up well in the shaft. The Imperial Copper Co. at Custer Peak, started shaft work, and reports encouraging progress and satisfactory developments. The Deadwood Homestake Co. was organized, and funds are being raised to sink 100 ft. east of the Homestake. The Republic Mining Co., a reorganization of the Golden Gate Co., installed electric machinery and started on a plan of work destined to thoroughly develop the property. The Otho company is developing a property at Spokane, and for equipment a portion of the machinery in a mill at Mystic is being moved. The Cleopatra property has passed to the bondholders under a foreclosure sale, and a new company will be organized for operating it. The Minnesota company paid all of its indebtedness and back taxes, and development work will probably be undertaken before long. The Branch Mint company paid back taxes in full, and will probably attempt to operate this year.

The completion of the hydro-electric plant of the Dakota Power company, on Rapid creek, near Pacola, affords further electric energy for the Black Hills operators. A contract has been made with the Consolidated Power & Light Co. to sell the surplus, about 1000 hp., to the latter.

THE BLACK HILLS DISTRICT.

MONTANA

Operations of smaller companies in Montana are overshadowed by those of the Anaconda Copper Mining Co., which with its copper mines, mills, and smelters, coal mines, and timber lands, is the greatest factor in the mineral industry of the state. To discuss its operations in detail would require too much space, and only general features can be touched upon. Production from the mines was considerably increased, as a reflex of the increased price of copper. Increased use of electric haulage underground, and the progressive substitution of compressed-air hoists for the old steam hoists on the surface, are the most notable features of mining work. The compressed-air hoisting system was described in the *Mining and Scientific Press* of November 2, 1912, p. 554. At Great Falls it is announced that the smelting plant will be reconstructed, at an estimated cost of $2,500,000, the present plant being out of date. At Anaconda the mill is being partly remodeled following an improved flow-sheet developed at the Great Falls plant. The Anaconda company has donated $25,000 toward the construction of a state sanitarium for patients suffering from tuberculosis and miner's consumption. The state recently voted $20,000 for construction and $5000 annually for maintenance, and construction has been started near Anaconda. The former agreement between the mining companies and the workmen expired during the year, and after some parley a new three-year agreement providing for a minimum wage of $3.50 per day underground and $3 on the surface was made. When copper sells between 15 and 17c. per pound, this rate is to be increased 25c. When copper is over 17c. the rate for underground work is to be $4, and when over 18c. for surface work $3.50 will be paid.

Purchase of the Southern Cross mine, in the Georgetown district, by the Anaconda Copper M. Co., and completion of an 18-mile extension of the Butte, Anaconda & Pacific railroad through Warm Springs canyon to the property has greatly stimulated the development of adjacent properties, and good finds have been made in Stuckey's gulch and elsewhere. The Southern Cross ore carries a fair content of gold and contains 20% excess iron, so that it forms a welcome addition to the smelting charge.

The Butte & Superior Copper M. Co. has exhibited a variety of changes during the year. It is a zinc producer, despite its name, and at the beginning of the year shipped its ore to the old concentrator at Basin, while its own plant was under construction. A new hoist has been erected and a new head-frame is under construction in order to permit hoisting of a greatly increased tonnage. The 1000-ton mill was finished about the middle of the year, and in it ordinary concentration was followed by the Hyde flotation process. The Minerals Separation, Ltd., in the employ of which Mr. Hyde had formerly been, promptly brought suit against the Butte & Superior company for infringement. Meanwhile, Hayden, Stone & Co. and the Utah Copper interests acquired the control of the company and certain changes have been made in the mill, which has been treating about 400 tons per day. G. O. Bradley and F. G. Janney will have general supervision of the changes made. The capital stock of the company has been increased to $3,500,000, the increase of $1,000,000 being intended for the exploration and purchase of other properties, and 15 claims lying north of the Butte & Superior have been taken under option for $536,000. A. B. Wolvin has recently organized the Butte-Duluth Mining Co. to take over the Montgomery and Macarona and portions of the Altoona, Amazon, and Colleen Bawn claims, lying east of the East Butte and adjoining the Bullwhacker Copper Co. The ground is supposed to contain large bodies of silicious copper ores, which are to be mined with steam-shovels and treated in a 500-ton leaching plant, of which a 100-ton unit is under construction. A 50-ton leaching plant has also been constructed at the Bullwhacker, which is owned by Patsey Clark, but it is not at all certain as yet that the process can be carried on at a profit.

The East Butte Copper Co. has done well during the year, and under the capable management of Oscar Rohn the plant has been enlarged and improved without interrupting its operation. The discovery of some good ore-bodies has much improved the position of the company, and from the operating profits $2,000,000 has now been paid over on the $2,500,000 bond issue held by Pittsburg banks, and 100,000 shares of East Butte stock has recently been turned over to the old Pittsmont company in payment for its interests. According to the report of the State Mine Inspector, the development work in the Butte district as a whole shows nearly a 60% increase over preceding years. He also estimates that the general introduction of electric power in the mines will finally effect a saving of 1c. per pound in the production cost of copper.

The advent of cyanidation in Butte was signalized by the construction of the 200-ton plant of the Butte Central Copper Co., built by the Colorado Iron Works under the direction of John E. Rothwell, in which it is expected to save 64% of the gold and 40% of the silver by concentration, making an added recovery of 35% of the gold and 43% of the silver by cyaniding the tailing. The plant was expected to begin work at the end of the year.

Interesting experimental work has been in progress at the Butte Reduction Works, where tests have been made upon the tailing dump, in which it is estimated there is 1,500,000 tons containing 1% copper. Both the Minerals Separation, Ltd., process and McQuisten tubes are being experimented with to determine which will make the greater saving at the lesser cost. The Timber Butte Milling Co. was incorporated early in May by W. A. Clark, W. A. Clark, Jr., W. D. Mangam, A. J. Johnson, and J. K. Heslet, with a capital of $100,000, to construct a zinc concentrator for the Elm Orlu and Poser mines on the west side of Timber Butte, 2 miles south of Butte. The Elm Orlu was operated at a loss of $22,000 during the year ended June 1, having been shut down from beginning of 1912 because of the burning of the Butte Reduction Works.

The Boston & Corbin Copper & Silver Mining Co. expects to have its 200-ton concentrator for milling a chalcopyrite ore, at Corbin in Jefferson county, in operation by next February. The Corbin Copper King M. Co. was incorporated to take over the property of the Montana-Corbin Copper Co. The La France Copper Co. at Butte was sold by the sheriff on December 3, and was bid in by a representative of the Lincoln Trust Co., the bondholders, for $100,000. The shareholders will receive nothing.

At Marysville the St. Louis Mining Co. is constructing a 100-ton milling and cyanide plant to handle the bodies of low-grade ore remaining in the Drumlummon mine. Work in the Radersburg district has been greatly stimulated by the repeated announcement that a branch line of the Chicago, Milwaukee & Puget Sound railroad will be built from Three Forks. The Kalispell-Lincoln G. M. Co. has constructed a 3-stamp mill on its property in the West Fisher district, 35 miles south of Libby. At the Bald Mountain mine, in Lewis and Clark county, Thomas Cruse has a 20-stamp mill and cyanide plant at work and is turning out about $40,000 per month. The Kendall gold mine, at Kendall in Fergus county, has finally closed down after 13 years of operation, and having paid $1,500,000 in dividends on an original purchase price of $400,000. In the Cottonwood district, 25 miles south of Billings, a good deal of interest has been awakened in the possibility of developing oil and gas, and the Yellowstone Oil & Gas Co. and the Billings Oil Co. have been formed. Drilling has just been started.

The Barnes-King has purchased the North Moccasin for $150,000, of which $5000 is cash and the remainder is to be paid out of net profits of mining operations. The Moccasin will be worked from the 400-ft. level of the Barnes-King. The Piegan-Gloster has also been secured for $125,000. The Barnes-King started its 100-ton cyanide plant in December. The Calumet & Montana has acquired the King Solomon mine, 2½ miles from Clancy. The Snowshoe mine, 12 miles from Libby, has been taken over by a new management, R. C. Davis in charge, and a mill constructed to treat the silver-lead ore. The Amazon-Montana Development Co. canceled its lease on the Amazon, 30 miles east of Butte, and has taken over the Florence silver-lead mine at Neihart as the Florence Mining & Milling Company.

Development of hydro-electric power and its application

to industry has been one of the marked characteristics of the year. Early in December a $100,000,000 merger, known as the Montana Power Co., was formed in New Jersey to take over the Butte Electric & Power Co., Billings & Eastern Montana Power Co., and the Montana Power Co. The Great Falls Power Co. will not enter the merger, but some of its largest shareholders are interested. This is probably a step in the long-talked-of electrification of the transcontinental railways. The Butte, Anaconda & Pacific has nearly completed the electrification of its line, at an estimated cost of $1,000,000, and will use 8000 hp. The Chicago, Milwaukee & Puget Sound is said to be planning to electrify its line over the continental divide, and possibly the lines through the Belt and Coeur d'Alene mountains. If this is done, it will use 16,000 to 20,000 hp. more.

WASHINGTON

Interest in this state has centred mainly in the Republic and Chewelah mining districts, in Ferry and Stevens counties, respectively. The mines and mills of the former districts were described by Sidney Norman in the *Mining and Scientific Press* of August 24, 1912. Republic was resurrected about 4½ years ago, and there are now over 400 men employed, and a population of over 2000 people. The North Washington Power & Reduction Co. was organized with the idea of treating ore from the Republic mine, and customs shipments. During its year ended May 31, the company shipped 20,646 tons of ore, worth $382,118, and made a profit of $42,737. A power-line was built from Grand Forks, British Columbia, to Republic, and the cyanide plant enlarged to 5000-ton capacity per month. In May 3077 tons was treated. The Republic Mines Corporation, which paid $85,000 in dividends in 1912, opened a stope over 70 ft. long on the 400-ft. level, while good ore was mined from above the 500-ft. level. At the San Poil the 125-ton mill was started. The crushing department consisted of a Williams pulverizer, which has 32 swinging hammers fixed to a central spindle rotating at 600 r.p.m. From Eureka gulch, the Knob Hill company shipped ore averaging $32.31 per ton to smelters, and paid $5000 in dividends. The Hope Mining Co. is building a mill. The Anaconda Gold Mining & Reduction Co. was organized with a capital of $2,000,000 to take options on mines in the Republic district. In an adit 1268 ft. long, the Faithful Surprise Co. intersected two veins. The Quilp Mining Co. pays dividends from royalties on ore mined by the Imperator-Quilp Co. The latter recently sued the former for $410,000, alleging fraud in the terms of working. The Washington Water Power Co., of Spokane, is investigating Republic and Chewelah with a view to extending power-lines into the districts. Spokane people have been largely instrumental in developing the copper-silver veins of the Chewelah district. At the United Copper mine, the largest producer, one vein has been opened by an adit to a depth of 500 ft., and driving has proved an ore-shoot 1400 ft. long. A lower adit, which is being driven from near the mill, will give 600 ft. extra depth. Dividends amounting to $50,000 were paid. The Copper King, north of the United, is working on the same vein to 400-ft. depth. The Aurora group lies north of the Copper King, and is being developed by a drift from the 400-ft. level of the latter mine. A plant to cost $100,000 will be erected. At Blue creek, the Liberty Copper Mining & Milling Co. is building a 100-ton mill. During the year the International Power & Manufacturing Co. decided to utilize 10,000 hp. of the Pend Oreille, and erect a power-plant for various manufactures. The Superior copper mine, at Brown's Lake, was leased, a lode of copper-silver ore 9 ft. wide was opened, and shipments made. Other properties are being prospected with fair results. In Pacific county there was a rush to South Bend, and one party of 50 men came into collision with civil authorities through their occupying the Ellsworth ranch. The Tacoma Smelting Co.'s plant, in Pierce county, was overhauled and enlarged. The electrolytic refinery was treating 30 tons of copper daily, while the balance of production was shipped to Eastern refineries. The Arnold Engineering Co., of Chicago, studied the Sultan district of Snohomish county, and found that 106,000 hp. could be developed by a hydro-electric plant, at a cost of $5,630,000. Spokane has been a busy mining centre during the year for mines in Washington, Idaho, and British Columbia, and the stock market has been well patronized. The Spokane section of the A. I. M. E. met on February 17 and July 26; papers were read and mines inspected. The important meeting of the year was that of the American Mining Congress, on November 25, and following week, when important subjects were discussed and the mines of the Coeur d'Alene district visited.

OREGON

Mining has been conducted on a small scale at a number of properties throughout this state, mainly in Baker, Grant, and Josephine counties. At the Bonanza mine, in which Pittsburg men are interested, several veins are being developed, and an adit 1800 ft. long is being driven. After being full of water for about 10 years, the Mammoth mine is being reopened to 400-ft. depth. The Cornucopia Mines Co. has built an electric-power plant of 400-kw. capacity. Copper ore has been mined from several claims below Ballard Landing on Snake river. In an adit, the Laclede Consolidated Gold & Copper Co., near North Powder, has opened an 8-ft. lode. An electrically-driven 20-stamp mill is in operation at the Virtue mine. The North Pole mine has been shipping about 10 tons of ore per day to the Tacoma smelter. At the Rainbow mine a 15-stamp mill, embodying amalgamation and cyanidation, with a tube-mill, Kelly filter-press, and Merrill zinc-dust precipitation, was built. Power is supplied by the Idaho-Oregon Light & Power Co. A good deal of work is being done at the North Fork placer mines, and the Yuba Construction Co. has built a dredge for the Powder River Dredging Company.

In Grant county, the Ben Harrison mine, at Granite, has 20 stamps, concentrating tables, and a tube-mill working. The mine has been opened to 500-ft. depth by an adit and shaft 100 ft. below this. An electrically-driven 16-drill compressor supplies air for the mine. During the year it was decided to build a railroad from Grants Pass in Josephine county, up the Applegate river, to the mines of the Blue Ledge district. On Grave creek, 14 miles from Grants Pass, 3000 acres of land was bought by the Oro Power & Light Co. of California. Drilling is being done with a view to dredging. The Alameda smelter was started, and a 200-ton mill is to be built. The Oriole company erected a 50-ton mill, costing $70,000, at Grants Pass. On the Rogue river, the Minnehaha Gold Hydraulic & Dredging Co. was building a dredge to cost $50,000. The West Coast company has been producing gold from the Champion mine and mill. Ore from the Musick claim is sent to the 30-stamp mill over an electric line about one mile long. The Eureka corporation was to erect a custom mill at High Grade, in California, just over the state border. At Applegate, in Jackson county, a chlorination plant of 100-ton capacity was erected at the Oregon Strong Ledge mine. In Douglas county the Beaver Hill mine, near Anchor, cut a vein at 400 ft. in an adit, and another adit is being driven. The Oregon-Colorado mine is 900 ft. deep, and a smelter was to be erected for the copper ore. In January lectures on mining geology were begun by the mining engineering department of the Oregon Agricultural College, at Baker City. At Medford, in February, the Southern Oregon and Northern California Mining Congress held a meeting. There were exhibits of ore and machinery, and discussions on various mining topics.

ALASKA

*This territory had a good year in 1912, and preparations in progress indicate that the year just commencing will be one of increased activity, from Juneau to Nome. The past season lasted longer than usual; consequently prospecting, dredging, and other work has prospered. A good deal of

*Based upon advance sheets of the annual report upon the mineral resources and production of Alaska prepared under direction of Alfred H. Brooks of the United States Geological Survey.

development will be done this winter, and each succeeding winter sees more accomplished in this way. The Treadwell group continues to treat 120,000 tons of ore per month, and the erection of a 6000-ton mill for the Alaska Gold Mines Co. should be finished this year and help to swell the output of gold. At Katalla, a petroleum field is being developed, and during the year the Bureau of Mines mined 800 tons of coal for a naval test. In the Copper River district the output of copper ore increased in spite of snowslides and washouts on the railroad. Fairbanks is now more interesting from the fact that there are 16 stamp-mills in operation. At Iditarod more dredges are likely to be erected on Flat creek.

It is estimated that the total value of the mineral output of Alaska in 1912 was $21,850,000, compared with $20,650,000 for 1911. The value of the gold output of 1912 is estimated at $16,650,000; that of 1911 was $16,853,256. It is estimated that the Alaska mines produced 28,940,000 lb. of copper in 1912, valued at about $4,630,000. In 1911 the output was 27,267,871 lb., valued at $3,364,584. The silver production in 1912 is estimated to have a value of $300,000, as compared with $243,923 for 1911. The value of all other mineral products in 1912, including tin, marble, gypsum, coal, and petroleum, was about $260,000, compared with $176,942 in 1911. The total value of Alaska's mineral production since 1880, when mining first began, is, in round numbers, $229,000,000, of which $202,000,000 is represented by the value of the gold output. The total output of copper in Alaska since 1901 is about 90,000,000 lb., valued at about $13,145,000.

The increase in the value of Alaska's mineral output is to be credited to the larger copper output as compared with the previous year. While no new copper properties were put on a productive basis, a large amount of development was accomplished. The gold-mining industry was marked by important advances in developing lode deposits. Work was continued on a number of large lode-mining enterprises in the Juneau district, and considerable advances were made at Fairbanks and in other districts. In addition to this, promising discoveries of auriferous quartz were made at Port Wells and in the Innoko-Iditarod region, as well as in other parts of the territory. The output from the placer mines was less than in the previous year. On the other hand, discoveries of rich auriferous gravels were made on Hammond creek and in the Koyukuk valley, and workable placers were found in the Ruby district. Extensions of gold-bearing gravels were also found in several of the older districts. The building of large plants has not gone ahead rapidly enough to insure the keeping up of gold-placer production. It is significant, however, that the output on Seward peninsula was practically the same as that of 1911. The maintenance of this output is to be credited to the dredges. The data at hand indicate that in 1912 about 40 dredges were operated in Alaska, and a number were under construction. Of these, three are in the Fortymile, one in the Fairbanks, one in the Birch Creek, and one in the Iditarod district, one on the Kenai peninsula, and the rest on Seward peninsula. There has been no change since the previous year in the opening of coalfields. One coal mine was operated for a part of the year at Chignik, on the Alaska peninsula, and the mining of coal for local use was carried on in a small way elsewhere. Investigations were made in the Bering River coalfield under the joint auspices of the Navy Department and the Bureau of Mines, to determine the availability of the coal for naval use. One oil well was drilled at Katalla, and there was a small production of petroleum from this field, the oil being refined near the well, and the gasoline disposed of in the local market.

Except for the continuation of the work of the Alaska Road Commission in the building of wagon-roads and trails, there was no marked improvement in transportation facilities during the year. The total railway mileage for Alaska in 1912 is 465, the same as during the previous year. Most of the railways were operated, except those on Seward peninsula. The Copper River & Northwestern was blocked by landslides for about six weeks in the early fall. In accordance with an Act of Congress, the Alaska Railway Commission was appointed about September 1 and spent about three months in the territory investigating railway routes and conditions of transportation. The report of this Commission is in preparation.

It is estimated that there were about 22 gold-lode mines in Alaska that made some production in 1912, compared with 18 in 1911. In addition to this, development work was done on many lode prospects widely distributed over the territory. The value of the output from the auriferous lodes in 1912 is believed to be about $4,600,000, an increase of about $400,000 over that of the previous year. This increase must in large measure be credited to the Treadwell group of mines, but there was also a considerable production from various small properties in different districts. The most notable mining advances in the territory during the year were those in the Juneau district. The Treadwell mine increased its gold output. Work was continued on the 6000-ft. adit of the Alaska Juneau mine and was begun on an adit for the Alaska Gastineau, which will be about two miles in length. It is to undercut the Perseverance orebody, which, with adjacent properties on Sheep creek, has passed under one management. The ore is to be carried to a mill of 6000 tons daily capacity, which is to be erected at tidewater. The Cliff mine, in the Valdez district, continues to be the only gold-lode property in the Prince William Sound region which has made a considerable output. In the aggregate, however, considerable ore has been recovered from other properties incidentally to development work. Although the output from the Fairbanks placers has decreased, there was far greater activity in lode mining and prospecting than in the previous year. From the stamp-mills the average recovery of free gold is about $50 per ton. Lode prospecting has continued with increasing activity during the year, and probably more than 200 men were engaged in this work. As a result a number of quartz veins were disclosed, some of which promise well. The notable features of the lodes are their great number, small size, and high tenor. Most of the veins from which free gold can be obtained by panning are composed almost entirely of quartz, with sulphides either absent or present only in small amounts. Stibnite is the most common of the sulphides.

The Jumbo and Rush & Brown mines were the only considerable shippers of copper ore in the Ketchikan district. It appears that the Mount Andrew mine was idle for most of the year, but plans have been formulated for systematic development. The Kennicott-Bonanza mine is the only one in the Kotsina-Chitina district from which shipments were made in 1912, but a large amount of development work was done on other properties. The concentrator erected in 1911 at the Bonanza mine was operated during 1912. At the east end of the field, work was continued on the Mother Lode, Nikolai, and Westover properties, and also on a property on an island in the Kennicott glacier. Prospecting and development work were especially active in the vicinity of Kuskulana river. Here the largest operations were those of the Great Northern Development Co., which completed about 5000 ft. of development. The Alaska Consolidated Copper Co. carried on development on Nugget creek, and on the Rarus group of claims. The Alaska United Copper Exploration Co. continued work on the Blackburn group of claims on Porcupine creek. In addition to the above, a large number of claims were being opened in the Kuskulana region during the summer of 1912. This field is now readily accessible from the railway, and a branch has been surveyed which would permit the shipment of ore. On Prince William Sound shipments were made by the Ellamar Mining Co., the Three-man Mining Co., the Landlocked Bay Copper Mining Co., and the Beatson Copper Co., all on Latouche island. In addition to these productive properties, there were a large number of claims at which development was carried on, some of which give promise of soon reaching a shipping stage.

In connection with tin-mining, the dredge which was installed on Buck creek last year was operated throughout the open season of 1912, as elsewhere noted. The Lost River lode-tin property has been bonded, and is now being systematically developed. The results of these operations

in 1912 are reported to justify further investments and the erection of a mill. This property promises to become the first productive lode-tin mine in Alaska.

The returns from the Alaska placer mines are far from being complete, but information at hand indicates that the value of the output in 1912 was $500,000 below that of 1911. The Fairbanks district continues to lead in the production of placer gold. It is estimated that between 130 and 140 different plants were operated, and 900 to 1500 men were employed. In the Circle district 27 mines were worked in winter and 32 in summer, employing from 60 to 100 and 145 to 175 men in each season, respectively. The Fortymile district had a good season, also the Koyukuk section. About 150 men were working in the Ruby Creek district, and production was over $150,000. In the Iditarod district 34 mines, distributed on six creeks, were worked, and 650 men employed.

THE PITTSBURGH DISTRICT

By Stephen L. Goodale

In spite of its being a presidential year, 1912 has been a very satisfactory one in the Pittsburgh district. Prices have been good and increasing, and at the close, in many lines, a considerable bonus is being secured for early deliveries. The mills entered the year with their order books filled, although the prices at which most of the work had been taken were low. The pig iron production for the whole country reached in October and November the remarkable rate of 32,600,000 tons a year—the previous high record being a million tons less. Production and prices in the Pittsburgh district are shown in the following table:

MONTHLY PRODUCTION AND PRICES

	Furnaces in blast	Pig iron output.	Basic iron at Valley furnace.	Bessemer iron at Pittsburgh....	Prompt furnace coke at oven.
January	35	495,099	$12.35	$15.05	$1.82
February	40	525,445	12.25	14.90	1.78
March	44	623,450	12.80	15.10	2.12
April	47	599,774	13.00	15.15	2.39
May	47	634,160	13.00	15.15	2.28
June	45	591,178	13.15	15.15	2.02
July	45	583,745	13.35	15.15	2.21
August	43	584,601	13.85	15.45	2.26
September	42	546,829	14.25	15.90	2.36
October	43	621,813	16.00	17.80	3.52
November	47	567,868	16.40	18.00	3.90
December	40	.....	....	....	...

Ore prices for 1913 have been established at a high level by general buying with no reduction made in the guaranteed iron content. Representative prices were: Old Range, bessemer, $4.40; Mesaba bessemer, $4.15; Old Range non-bessemer, $3.60; Mesaba non-bessemer, $3.40.

The large steel companies have purchased considerable iron during the year in addition to their own output. One firm is said to have bought 40,000 tons of bessemer iron for first quarter 1913 delivery in Pittsburgh at $17 to $17.25 at Valley furnace. At the close of the year practically all the companies in the district are working nearly to capacity. The U. S. Steel Corporation, for instance, is working 95 to 96% of capacity. Prices are good as may be seen from the foregoing table, based on *Iron Age* quotations, and the outlook for a continuance of the favorable conditions seems to be promising. There has been practically no lessening of the steel trade since the election. Car shortage was felt about the middle of February, but did not reach a serious proportion until the fall months. It culminated early in December with a net shortage for the United States and Canada of 50,000 cars. This was severely felt by both blast-furnace and coke operators. Several furnaces were banked for brief periods because of inability to secure coke, and it is now feared that the available coke supply may run short during the winter months. In October the unusual condition prevailed of prompt furnace coke ruling some 50c. per ton higher than contract coke. Among the coal operators in general the year has been good though with but few large new undertakings or striking developments. Several times during the year shortage of cars restricted shipments. The business of the Pittsburgh district has had the help of the cut of 10c. per ton in the freight rate from the district to the Lake, which was made in May.

New Construction.—The usual plant extensions and ordinary improvements were made during the year, and in addition the following more notable new work may be mentioned: The Carnegie Steel Co. has installed two 60-ton open-hearth furnaces at the Clairton plant. Fourteen 80-ton open-hearth furnaces are being built at the Edgar Thomson works. Four to six of these are expected to be completed by next April. The Jones & Laughlin Steel Co. is building a battery of 240 rectangular beehive ovens at Aliquippa, to be ready for operation about the first of the year. The auxiliary waste-heat saving system is expected to develop some 4000 boiler horse-power. The Aliquippa blast-furnaces are now all in blast, and the steel plant was started during the year, including a converter and four large Talbot furnaces. The tin plate capacity was practically doubled during the year, 24 hot mills being now in use. All finishing departments have been active. At the Eliza furnaces two units of Dwight-Lloyd sintering machines have been erected, each of 100 tons daily capacity. The Pittsburgh Steel Co. is building two blast-furnaces at Monessen, Pa., one of which is expected to be ready in April, the other in June. The Pittsburgh Crucible Steel Co. has installed eight 60-ton open-hearth furnaces at Midland, near Beaver, together with 40-in. blooming mill and several finishing mills. The Union Steel Casting Co. has doubled its capacity by the addition of two 25-ton acid open-hearth furnaces, together with the necessary molding space and finishing equipment. An interesting item, as indicating the growing scarcity of natural gas, is that the Pittsburgh Plate Glass Co. has installed three Chapman rotary producers in its plant at Tarentum.

The Union bridge across the Allegheny at the Point is progressing rapidly. The automobile thoroughfare to East Liberty is being completed by the construction of two large reinforced concrete bridges in the Bellefield Shadyside district. One, spanning the Pennsylvania tracks, is being supported on the new steel centring during construction. Steel barges are rapidly replacing the older wooden ones in the river coal and sand trade, both the American Bridge Co. and Jones & Laughlin Steel Co. building a large number of the new craft.

General.—Among the developments in metallurgy during the year, the Carnegie Steel Co. has been trying tar as an open-hearth fuel at North Clairton. An improvement in the mud-gun has been made which permits of closing the tap hole of a blast-furnace without the necessity of shutting off the blast. A considerable number of heat-treatment furnaces have been built, and the temperature control has been materially improved. At the University of Pittsburgh the most interesting technical developments have been the great success of the Industrial Research department and the Co-operative Engineering plan. In the former there are now 29 fellows working, many of them being experienced men, on 15 problems of industrial importance. One of these problems is the smoke nuisance, in connection with which it is interesting to note that at Pittsburgh, in 1911, 19,000,000 tons of coal was consumed and 53,000,000 handled in or through the city as compared with 16,500,000 and 36,000,000 tons, respectively, in the case of Greater New York. The Carnegie Institute of Technology has made notable additions to its metallurgical laboratories during the year; among which may be mentioned an electric steel furnace and a well designed milling plant. Interesting work was also done last summer in the factories of the Westinghouse Electric & Manufacturing Co., where a group of 29 men from 25 different colleges in 19 different states—members of engineering faculties—worked as regular employees of the company under the direction of the head of the department of the electrical engineering of Colorado College. This was done with the idea of bringing instruction into closer touch with practical conditions.

THE YEAR AMONG THE MINES ABROAD

Foreign mines and mining are attracting increasing attention in the United States, as it becomes possible to spare both engineers and capital from home development. We present below in most condensed form summaries of development in 1912 in those countries in which North Americans are mainly interested. Additional details are given in special articles on other pages, and more complete accounts of the present state of mining in the Transvaal, Rhodesia, the Congo, Australia, New Zealand, along the west coast of South America, and elsewhere, have been prepared and will appear in later issues.

CANADA

Ontario and the Eastern Provinces

The principal interest attaches to the Porcupine goldfield, where active production of bullion began during the summer. The Dome mill commenced operations in March, but the delays and accidents incidental to starting a new plant of this character prevented steady work until the end of June. The Hollinger mill started crushing in June, and though for some time only low-grade ore was treated, operations proved so profitable that on November 2 the initial dividend, the first paid by any Porcupine mine, of 3% for four weeks, was declared, accompanied by an official statement that the profits amounted to $40,000 per week, which would enable dividends to be paid continuously on this basis. The latest official figures available as to the output are the returns to the Ontario Bureau of Mines for the 9 months ended September 30, which give the production of gold as 53,488 oz. of the value of $1,117,335, as compared with 2185 oz. valued at $42,637 for the preceding 12 months. The bulk of this year's yield was from the Hollinger and Dome mines, the McIntyre and Vipond also being contributors. The rate of production during the last quarter of the year was expected to show a very considerable increase, but a general strike of miners belonging to the Western Federation of Miners took place. However, it is now considered that the strike is practically over. There are now eight mills either in operation or under construction in the camp, the latest being the 10-stamp mill ordered by the Three Nations which it is expected will be ready early in the spring. The cyanide process has been found a necessary adjunct to several of the plants. In the outlying Swastika district the pioneer mine, the Swastika, will put its 10-stamp mill into commission early in January, having a large quantity of ore in readiness. The Lucky Cross, in the same area, has ordered a mill for erection early in 1913.

While the production of silver of the Cobalt district for the year will probably be somewhat lower than that of 1911 it is expected to show an increased value. Owing to the higher price of silver, operations were resumed during the year on a number of prospects that had been idle. Low-grade shipments have almost entirely ceased and the proportion of bullion shipped as compared with ore shows a steady increase. The completion of the Nipissing mill for treating low-grade, with an aerial tramway for the transportation of ore, is one of the more noticeable economies effected. In October an important discovery made on the Seneca-Superior leasehold from the Peterson Lake gave a considerable stimulus to operations in the neighborhood of Cart and Peterson lakes. A vein of high-grade ore was found at the 200-ft. level underneath Cart lake and has since yielded rich returns. The deep mining policy has been successfully adopted by the Timiskaming and Beaver companies, the latter having attained a depth of 700 ft. and having the lowest level in the district. Exploration in the diabase has been on the whole encouraging, showing that the veins, on entering that formation, do not lose their silver content as a rule. They usually split up into three or four stringers; the wall rock between carries a good deal of leaf silver. Further development at the 700-ft. level will show whether the ore continues to be good for some distance below the diabase-Keewatin contact. The figures of silver production given by the Bureau of Mines for the first nine months of the year show an output of 22,231,451 oz., valued at $12,707,826, being 963,601 oz. less than for the corresponding period of 1911, while the increased price per ounce resulted in increasing the value by $1,114,090. South Lorrain contributed 616,692 oz., and Gowganda 449,281 oz. of this total. Several of the principal dividend-paying mines of Cobalt, the Cobalt Lake being the latest addition to the list, have materially increased their returns to shareholders, the McKinley-Darragh at the close of the year declaring a 20% and the Buffalo a 26% payment. The latter company has completed a refinery with a capacity of from 300 to 400 tons per month, and will hereafter ship its product in the form of bullion. With the construction of the Elk Lake branch of the Timiskaming & Northern Ontario railway, now nearly completed, a period of active development in the Elk Lake and Gowganda districts is anticipated.

The great demand for nickel for naval construction owing to the war in Europe, has caused a revival of activity in the Sudbury nickel mining field, where the old companies are extending their operations and new organizations are preparing to enter the field. The Canadian Copper Co. has enlarged its ore resources by buying a portion of the Northern range from the Lake Superior Co., and has opened up the Frood mine and other old workings which have been closed for years. The Mond Nickel Co. is putting up a large smelter and preparing to turn out nickel-matte on an extensive scale. The Dominion Nickel-Copper Co., which has expended some $250,000 in diamond-drilling and has acquired more extensive holdings than any other company in the field except the Canadian Copper Co., and done extensive development on the Whistle property, is about to erect a large smelter. A great deal of development work has been done in the district this season and the output next year will show a heavy increase. In addition to the production of the Sudbury region another source of nickel has been developed in the Alexo mine on the line of the railway, from which considerable shipments have lately been made to the smelter of the Mond company at Victoria mines.

While the production of iron ore in Ontario shows a decrease, the output of pig iron has increased from 296,856 tons for the first nine months of 1911 to 452,021 tons for the same period of this year. The Helen mine continued to be the principal producer of ore. Those in charge of the Moose Mountain mine, north of Sudbury, have succeeded in perfecting the Gröndal process of magnetic concentration as applied to their ores and have begun the turning out of briquettes of bessemer quality from ore regarded as valueless. The output of the Dominion Iron & Steel Co. of Sydney, Nova Scotia, in pig iron and steel shows a large increase, owing to the blowing in of a new blast-furnace, and the production of coal by the Nova Scotia companies considerably exceeds that of 1911.

British Columbia

By E. Jacobs

Production.—While returns are incomplete, there is good reason to look for final figures showing that the value of the mineral production of British Columbia in 1912 reached a total of between $31,000,000 and $32,000,000. As the highest value of production in any earlier year was that of 1910, with a total of $26,377,066, it is expected that the increase for last year as compared with that total will have been fully 20%. This increase is not due to higher prices so much as to greater production of nearly all minerals that are mined in considerable quantity in the province, the only exceptions being gold and coal, and these in comparatively small quantities. The 1910 output of gold was approximately 20,000 oz. greater and that of coal grew 98,000 tons. A preliminary estimate for 1912 gives the

following figures: Gold (placer and lode), $5,750,000; silver, $1,530,000; lead, $1,400,000; copper, $8,300,000; zinc, $300,000; coal and coke, $10,830,000; miscellaneous, $3,800,000; total, $31,910,000.

Cariboo.—An unusually dry autumn adversely affected hydraulic placer-gold mining, so that the yield was smaller than would have been the case with sufficient water for gravel-washing throughout the season. The output of placer mines in Cariboo division of this district is estimated as having been similar to that of 1911, but expectations of an increase in Quesnel division are thought to not have been realized. The district lacks railway transportation facilities, but lines are being constructed.

Cassiar-placer.—Notwithstanding a short season in Atlin division, an increase in quantity of placer-gold recovered has been reported. In the parts of the Skeena country through which the Grand Trunk railway is being built, development of silver-lead properties has been in progress, in some instances with promising results, so that ore production in 1913 is looked for. The further development of coal measures still awaits the completion of the railway through the parts it will serve. In the Groundhog field, where anthracite has been found, prospecting was done, but until this part of the district shall also be opened by a railway, little important development is likely. The Granby Consolidated company's operations on Observatory Inlet, where it has done much development work on its Hidden Creek property, constituted the most important advance in the middle or upper part of the Coast district, for already between five and six million tons of copper ore is "estimated in sight" and at least as much more "probable ore" is believed to also occur. Construction of smelting works, to have a treatment capacity of 2000 tons of ore per day; railway, buildings, and shipping docks; and development of a hydro-electric power for mine and smelting works have all been contracted.

East Kootenay.—In metalliferous mining, the most important operations have been at the Sullivan lead mine, which is in part taking the place of the nearly exhausted St. Eugene, for years the chief lead-producing mine in Canada. The Monarch, a lead-zinc mine in northeast Kootenay, was also operated. Construction of the Kootenay Central railway is being continued, so other mines are expected to ship ore next year, when transportation shall be available. Coal mining in southeast Kootenay was active, three companies—the Crow's Nest Pass, Hosmer, and Corbin—together mining 1,300,000 long tons of coal, of which 400,000 was made into 263,000 tons of coke.

West Kootenay.—In Ainsworth division, some 33,000 tons of ore was mined and concentrated at lead-silver mines, the Consolidated company and others worked mines in the old Ainsworth camp, and the Utica and Retallack & Co.'s mines also contributed to production. In Slocan there was much activity, with important deep-development at the Lucky Jim (zinc), Rambler-Cariboo, Payne, Surprise, Slocum, Slocum Star, Noble Five, Standard, Van-Roi, and Hewitt-Lorna Doone mines, most of which mine silver-lead-zinc ores. Aerial tramways and new concentrating plants were put in for the Rambler-Cariboo and Standard mines, and similar facilities will soon be completed for the Hewitt-Lorna Doone. The Standard and Van-Roi both shipped much silver-lead and silver-zinc concentrate.

Nelson.—The operations of the Consolidated and British Columbia Copper companies at mines within a few miles of the town of Nelson were features of the year. Gold mining and milling also made progress, near Nelson and in Ymir, Sheep Creek, and Erie. Mining lead ores near Salmo had attention as well. No important advance was made in either reduction of lead-zinc ores or proving that platinum metals exist near Nelson, though much notoriety resulted from claims made in newspapers.

Trail Creek.—Mining at Rossland and smelting and refining at Trail were well maintained. The Consolidated Mining & Smelting Co.'s Centre Star and Le Roi mines are in excellent condition for continued production of gold-copper ore, and developments in them and in the neighboring mines of the Le Roi No. 2, Ltd., assure the maintenance of ore production here on a similar scale to past and other profitable years. Both companies mentioned paid dividends. Many improvements were made at Trail.

Boundary District.—Copper mining operations of the Granby and British Columbia Copper companies gave record results, for about 1,900,000 tons of ore was mined and smelted, and 33,000,000 lb. of copper produced. The Jewel stamp-mill was worked late in the lear. Coal measures were prospected at Midway. Railway construction made good progress along the west fork of Kettle river, where there are several small mines. The Hedley Gold Mining Co. crushed 70,000 tons of ore and recovered gold valued at about $760,000. This company in 1912 declared dividends totaling $360,000, being 30% on its issued capital. It added a valuable group of claims to its property holdings. The B. C. Copper Co. explored copper claims situated near Princeton, using six diamond-drills besides doing much underground development. The Princeton Coal & Land Co. operated its colliery and shipped an increased quantity of coal. In Nicola country, the Nicola Valley Coal & Coke Co. found a new seam of coal, proved by diamond-drilling that its area of coal-bearing land is much larger than was known earlier, further developed several coal seams opened in earlier years, and shipped a comparatively large quantity of coal to outside markets. Mining gypsum has been commenced in Nicola valley.

Coast District.—The Britannia Mining & Smelting Co. made important progress, mining about 193,000 tons of copper ore, from which some 48,000 tons of crude ore and concentrate was shipped to Tacoma. Much underground development was done, and many additions were made to transportation, milling, and power-generating facilities. Coal mining on Vancouver island resulted in the production of about 1,553,000 long tons of coal. New coal mines are being opened by the Western Fuel Co., Canadian Collieries (Dunsmuir) Ltd., and Pacific Coast Mines, Ltd., respectively.

General.—Metalliferous mining companies together paid about $1,200,000 in dividends in 1912. This leaves out of account approximately $1,500,000 of earned profits of the Granby company, held for development and equipment of its Hidden Creek mines. Coal mining companies made ample provision for mine-rescue purposes, as required by provincial law, and the Government also established mine-rescue stations. Much railway construction was undertaken, thereby making new mining districts accessible.

MEXICO

Technical phases of progress in Mexico during the past year have been obscured by the great general interest in the political situation and outlook—matters which are discussed editorially and need no further comment here. It is somewhat surprising that, despite the persistence and universality of political disturbance, the total production of Mexico has not shown a great decrease. Some of the smelting plants, such as those of the American Smelting & Refining Co. at Monterey and Aguascalientes, were not troubled, being in districts not affected by the outbreaks, while the others were able to keep in operation with only a few temporary interruptions. Several of the large plants are increasing their output, the Greene-Cananea, for example, having a larger monthly production this year than ever before, and the decrease due to the general cessation of work by the smaller companies is thus counterbalanced by the increase of the larger ones that continue to operate. The unsettled conditions offer favorable opportunities for purchase by the larger companies, and the Peñoles Mining Co., for example, purchased the Paloma mines for ₱1,000,000 and is negotiating for the Cabrilla mines in Mapimi. The Greene-Cananea has bought properties, and the Naica silver-lead mines in Chihuahua were sold to French investors for several million pesos. The United States Smelting, Refining & Mining Co. has been examining properties with a view to purchase, and the Mezquital del Oro mines, in Zacatecas, the Casados in Jalisco, and other properties are under option to large foreign companies. Shipments of oil from Mexico continue large, and the mineral production as a whole is highly satisfactory, considering the present disadvantage under which the industry labors.

GERMAN MINING IN 1912

Success is written large across the story of German mining this year. In the production of iron, coal, potash, oil, and phosphates, there has been the greatest possible activity. In the first half of this year, the coal produced amounted to 84,710,000 tons; 12,800,000 more than in the corresponding half, and the production of iron was 8,420,000 tons, or 2,170,000 more than in the corresponding period. The production of pig iron increased from 11,507,748 tons between the months of January and September, 1911, inclusive, to 12,859,376 tons for the corresponding months of this year. The progress is steady month by month. The German metal-market has been firm from the start of the year, and has kept all the mines busy. Germany imports large quantities of raw materials, and the Germans are owners of extensive iron deposits in the north of France as well as in other lands; German enterprise in this direction has been particularly evident in Sweden this year, where iron deposits have been bought to such an extent that it has become a question in that country whether special legislation should not be enacted to protect the industry of iron-mining from a complete German monopoly. While Sweden is getting anxious for its natural supplies, the German iron-ore producers are holding meetings to consider the situation generally, and confidence is expressed that they will be able to so coördinate their operations as to make the Fatherland much more independent of foreign ore. This becomes of increasing importance in view of the exhaustion of some of the fields to which European iron-smelting countries have had recourse in the past, notably northern Spain. The anxiety of iron smelters the world over respecting the ultimate resources of iron supply is largely shared throughout Germany, where smelting is advancing with enormous strides. Little need be said of the coal industry, which naturally follows iron on general lines, except in respect to the efforts made by German operators to acquire foreign markets.

The mining industry that strikes the imagination most in Germany, however, is that of potash. As the months roll on, the position becomes more and more a problem. Before the potash law was enacted, the position was clear enough, and the potash syndicate, with the exception of the then two outside houses, Aschersleben and Sollstedt, had fair control of the situation. But it is different now. The law has been enacted which, it is maintained, because of its system of quotas and limits as to export prices, ensures a steady sale to any potash concern that can produce a minimum quantity of potash. The result, whether reasonable or not, has been a great crowd of new potash companies that have offered the shareholders the inducement of a certain sale for the goods, and as a necessary result (for many of them have begun to sink mines) there will be within a few months a largely increased production. The exports of potash this year have been large, exceeding those of the preceding year, but provision will have to be made for a larger export movement to overtake the great output that will result from the activities of the new companies. Meantime the Potash Syndicate appears to have got matters well in hand; for it has roped in the great outside companies, Aschersleben and Sollstedt, and is systematically working to practically coerce all the new companies into its organization as they come along. Conscious, however, of the pressure of supplies that will begin, no doubt with next year, the syndicate at a recent meeting took the wise step of making financial provision for an extensive propaganda the world over to get rid of its products. This propaganda will affect particularly North and South America.

Zinc works in Germany have been working at high pressure and obtaining much better prices than before. The petroleum industry in the country is showing progress, like the rest of the mining business, and is interested in the contemplated new legislation for the institution of a Government monopoly to control the business in the country and oppose the Standard Oil Co. Petroleum production, while not a leading industry, contributes a fair proportion of the country's requirements.

RUSSIAN MINING IN 1912

The Russian mining industries have been characterized by some remarkable features in the course of the year just closed. In neither coal nor iron mining has there ever been such a busy time as the present. All previous records of production have been surpassed, and the demand is so great as to constitute what is fairly described as a state of famine. Lowering of the tariff on pig iron has to some extent assuaged the shortage; but even now, with blast-furnaces working full time and every effort being made to supply the market both in South Russia, which is the principal field, and in the Urals, demand over-runs supply. During the first six months of the current year the quantity of iron ore produced was equivalent to 3,170,000 tons of 2000 lb., an increase over the corresponding period of the preceding year of nearly 23%. Most of this comes from the famous Krivoi Rog field, and the balance comes from the Kerch district. These figures, it should be stated in passing, refer only to South Russia. As to the production of coal, the increase has been extraordinary and yet fails to satisfy entirely the demands of the country.

Gold-mining presents a very unsatisfactory aspect, the principal reason being the deplorable events that took place in connection with the strike on the Lena Goldfields. One result has been a tremendous reduction in the gold output of Russia's premier gold area. Reports of returns are unsatisfactory, too, from the Far Eastern fields, particularly along the Amur railway now being built. Gold-mining is not so remunerative there as to neutralize the attractions of constant employment in railway construction. Farther west in the classic Urals, the gold output has been limited by the extremely high prices of platinum. Judging from the complaints that arrive from the placers to the effect that the high prices of platinum are attracting the workmen from the gold placers to those worked for platinum, it seems probable that in the Urals, too, there is going to be a shortage in the production of gold as compared with recent years. In other auriferous regions of Russia and Siberia the returns will probably be similar, or perhaps even superior, to those of the past. The introduction of dredges, hydraulic apparatus, and the like, is increasing in various Russian and Siberian gold-producing districts, and the gold used outside the areas specified above will probably be larger than ever. Platinum, a large element in Russia's annual contribution to the mineral wealth of the world, is discussed separately.

It is not possible, from data available, to give any idea of the quantity of copper ore that has been mined in Russia. This can only be inferred from the quantity of metallic copper that has been smelted. Monthly reports indicate an extraordinary increase in production. Although this large increase has taken place, it fails to satisfy the demand in the country, and considerable quantities still have to be imported. The leading copper ore areas are the Urals, the Caucasus, and Siberia. The Urals is the classic ground in Russia for copper production, and although for some years the region yielded its premier position as a copper-producing area to the Caucasus, it has again come to the front. The leading position as a copper-producing concern now belongs to the Kyshtim Corporation.

Zinc production of the country, hitherto confined to Poland, has developed rather remarkably in the Far East at Tetyuch, where a German company has been at work for some time and has produced considerable quantities of ore for treatment in the West. The Government hopes to arrange for treatment of this ore in Russia.

The production of petroleum in the country is now a struggling one. It is still large, but is unable to keep pace with past records. The Baku wells show signs of weakness, and production has gone back this year. Grozny is an area which after rapid advances looks due for a prompt collapse; probably more because of neglect on the part of the drillers in shutting off the water than for any other reason. Maikop does not yet respond to expectations, and there is no other oil district in Russia of importance at the moment. Tcheleken and the Ural Caspian areas are of purely local significance.

JAPAN

Figures covering the mineral production of Japan for the eight months, January to September, 1912, are available, and are as follows. The second column indicates the increase or decrease as compared with the corresponding period of last year.

MINERAL PRODUCTION OF JAPAN, JANUARY TO SEPTEMBER, 1912

		Change, %.
Copper, lb.	79,334,100	+0.77
Coal, tons	11,080,346	+1.48
Iron, tons	45,250	+1.32
Silver, oz.	3,344,480	+0.27
Gold, oz.	99,920	+1.16
Oil, bbl.	851,600	—0.75
Sulphur, tons	34,850	+1.12

The copper industry is the most important of all in the metal production of Japan, and the following table, showing the yield of the principal mines for the first six months of 1912, will therefore be of interest. Mines were active in the last quarter, and the total production is estimated at 126,000,000 pounds.

Mine.	Production, lb.	Change, %.
Ashio, Tochigi prefecture	9,169,430	+0.82
Kosaka, Akita "	8,937,690	+3.98
Besshi, Ehime "	8,535,960	+0.57
Hidachi, Ibaraki "	7,511,360	+2.04
Osaruzawa, Akita "	2,302,090	+0.59
Ikuno, Hyogo "	1,780,240	+1.12
Furokura, Akita "	1,773,560	—1.74
Arakawa, Akita "	1,438,220	+1.37

Japanese coal has been extending its market, and as a result of the strike in England was able to invade the Indian and Ceylon market this year, a shipment of 300,000 tons having been made to Colombo by the Chikuho collieries early in the year, and a later contract providing for a series of shipments, amounting to 150,000 tons, to be delivered at Colombo, Bombay, and other Indian ports. Prices show an upward tendency as a result. A reciprocal trade has sprung up in pig iron, of which Japan imports considerable quantities, chiefly from England. The Tata company of India has begun shipment of its pig iron to Japan, the product selling there at $15 per ton. As the cost of production in India is low, and the freight, as compared with England, is considerably less, the Tata company makes a good profit and the Japanese market is benefited as well.

Zinc, though not mentioned in the table above, has become of much importance of recent years, the output of zinc ore in 1911 being over 25,000 tons. The interesting work done at the Kamioka mine of the Mitsui company in the concentration of zinc ores by flotation was described by T. Inouye in the *Mining and Scientific Press* of June 29, 1912, p. 892. An 80% extraction is made, and 30 to 40 tons per month of product, containing 45 to 50% Zn is made. Until recently the zinc ore or concentrate has been shipped to Europe for treatment and spelter imported, as attempts at local reduction had failed for the lack of suitable material for the manufacture of retorts. Suitable clays have now been found, and the Mitsui company has constructed a smelting plant, under foreign supervision, at Omuta, near its Miike colliery in Kyushu, while another company has been organized to erect a plant at Osaka. Attempts at electrolytic refining have been made, but were uniformly unsuccessful. If the work of these smelters is successful, it may be expected that the output of the zinc mines will rapidly increase.

The Japan Petroleum Oil Co., of Echigo, has decided to double its capital, making it 20,000,000 yen. California rotary rigs have been imported, and have greatly reduced the time required for sinking wells. A well recently sunk to a depth of 1030 ft. is yielding at the rate of 1200 gal. per day. The company has started the construction of a 2000-gal. refinery at Raisatsu. The Hoden Oil company is paying dividends at the rate of 12% per year.

Japanese development work in Manchuria is mentioned in the review of China. The iron mines in Korea are developing even better than expected. North of Seoul and not far from Chinnampo deposits of good grade are being worked under government supervision and are producing about 200,000 tons per year. More properties are being developed and the total output will soon be largely increased.

CHINA

The most important change during the year in the mineral industry of China was the amalgamation of the Lanchow mines with the Chinese Engineering & Mining Co., Ltd. The latter is a British corporation which took over the Kaiping mines in 1900. The rights of the corporation have always been a subject of dispute, and a few years ago the Lanchow mines, a short distance north of the Kaiping mines, and in territory in which the Chinese Engineering & Mining Co. claimed the mining rights, were equipped under Government auspices at considerable expense, but showed no profit in working. The two companies have now been amalgamated under a joint administration known as the Kailan Mining Administration. Of profits up to £300,000, 60% is to be allotted to the British corporation and 40% to the Chinese company. Profits above £300,000 are to be divided equally. The Chinese Engineering & Mining Co. produced 1,453,546 tons of bituminous coal in 1911 (another report gives 1,170,163 tons as the output; the discrepancy is characteristic of statistics regarding output of Chinese mines). The Fushun mines, near Mukden, show a steady increase in production. The two large hoisting shafts are now in use, and the novel method of filling the worked-out ground with sand dredged from a nearby river is about to be tried. The completion of the Mukden-Antung railway has made Fushun coal available in Korea, and power plants to supply the gold mines in the northern part of Korea have been constructed. The coal is converted into gas and the recovery of ammonium sulphate, for which there is a good local market, is an important additional source of profit. The mines at Pen-hsi-hu, on the Mukden-Antung line have been developed with joint Japanese and Chinese capital, and as the coal yields coke of a good texture and iron ore deposits of good quality have been found in the neighborhood, an iron smelting plant has been started, also with joint Chinese and Japanese capital and good progress is reported.

The coal mines at Poshan and Fangtze, in Shantung, worked under German supervision, maintain a steady production, but, for a variety of reasons are unable to make any profits. The Peking Syndicate mines, in Honan, are increasing their output. The coal and iron mines and smelting plant of the Han-Yeh-Ping Iron & Coal Co. have been shut down, following the burning of Hankow during the revolution last year. It is reported that the smelting plant at Hanyang is not much damaged and can easily be reopened. At a meeting of the shareholders early in the year it was voted to increase the capital of the company from ₱13,160,000 to ₱30,000,000. If the ambitious scheme of railway building proposed by Sun Yat-sen is actually carried out, the company will be taxed to its utmost to supply railway equipment. It is reported that copper deposits have been found near the Ta-yeh iron mines, but it is probable that they are of no great value.

Antimony has apparently suffered a considerable setback, as a result of the revolution. C. Y. Wang has recently* described the operations of the numerous Chinese companies formed, many of them with little knowledge and less capital, to smelt antimony. The tin smelting plant, near Kochiu in Yunnan, mentioned in the review for 1910, has so far been without either funds to operate or a supply of ore to operate upon, but it is now reported that arrangements have been made to begin work. A French firm is said to be about to construct a branch line connecting Kochiu with the main line at Yuunanfu. Little progress can be made in the mineral industry while the government and finances of the country remain so unsettled. It is said that Sun Yat-sen, who is devoting his energies to the industrial development of the republic, has secured the advice of a well known American mining engineer, F. L. Cole, and when funds are available progress should be made.

**Eng & Min. Jour.*, October 26, 1912, p. 777.

SOUTH AND CENTRAL AMERICA

Interest among mining engineers and investors is turning rapidly toward Latin America. In San Francisco, New York, and London there is a growing conviction that in the great countries to the south are to be found the most important mineral deposits remaining to be mined. Better political conditions throughout the southern countries, increased knowledge of sanitation, and improvements in technology, are opening a field to industry that has long lain neglected. Arrangements are being made to give in the *Mining and Scientific Press* more space to South American development, and several articles have already been prepared for publication. A special review of 'Mining in the West Coast Republics in 1912,' written by Howland Bancroft, will appear in an early issue. For the present it will suffice to mention the more significant events of the year.

In Cuba development of the Mayari iron ore district is going rapidly forward under the effective management of the Spanish American Iron Co. The ore is making a distinct place for itself in the Eastern market. In Venezuela, easily the most important event of the year was the bringing in, late in the fall, of two excellent oil wells on ground controlled by the Barber Asphalt Co. The second of these wells yielded upward of 80,000 bbl. of 18° oil in the first week, and it now seems reasonably sure that an important supply of fuel oil will be developed near the east end of the Panama canal and on the sea. In Brazil, North Americans have been active in development of iron ore, and in December it was announced that arrangements had been practically completed to consolidate the newer American interests with those of English investors already represented by the Itabira Iron Ore Co., Ltd. A railroad to the coast, a harbor, and steamer lines to Europe are promised immediately. That there are great quantities of high-grade iron ore in Minas Geraes is now known, and it bids fair to soon become an important factor in the world's markets. In Goyaz several parties of engineers, under direction of R. E. Cranston, are now testing placer ground with a view to dredging. Lode mining continues to be best exemplified in the St. John del Rey. Diamond mining, at least so far as the United States is interested, received a setback through the ventilating of fraudulent promotions. In Uruguay and the Argentine railway building is active, but interest centres more in agriculture than mining.

For the present mining is most active in Chile, Bolivia, and Peru, the great republics of the West Coast. In Ecuador the South American Development Co. is responsible for the most important lode mining, while in Colombia several American concerns are active in developing both lode and placer mines. Neither of these countries has as yet attained the production of their neighbors to the south. In Peru the Cerro de Pasco, with its shipments of 3,500,000 to 3,700,000 lb. copper per month, stands as the best achievement, though the main supply of vanadium is also brought from that country by the American Vanadium Co. Bolivia, which supplies a fourth of the world's tin and has well founded hopes of furnishing an important share of the copper, attracted unusual attention this year because the completion of the Arica La Paz railway rendered it possible to open districts hitherto inaccessible. A false report of placer discoveries on the Tipuani drew prospectors to the district without result, but other placer fields are now being examined by competent engineers, and dredging or hydraulicking may soon be started. In Chile the nitrate industry continues to be of first importance. Based upon figures for the first part of the year, the output for 1912 may be estimated at 2,400,000 tons, and the reserves are known to be large. The Braden Copper Co. has made an excellent start, Fred Hellmann has gone down to manage the Chuquicamata, the Collahuasi is profitable, and other properties are coming in. Men and money are going rapidly into the West Coast republics, and the mineral industry is responding excellently to the stimulus. In Central America nothing startling has transpired. Wild tales of rich placers in Costa Rica proved unfounded. The New York & Honduras, Butters Salvador, and other well known properties continued their profitable course.

TRANSVAAL GOLD-MINING

By Rowland Gascoyne

Despite the large output previously obtained from the Witwatersrand goldfields, the production for 1912 will again constitute a record. The year, however, has not been a favorable one for obtaining capital for new ventures, and during the year no new producers have entered the field, though the Langlaagte Consolidated and Crown Mines have added to their milling capacity. The increased output of gold is therefore largely due to the dropping of additional stamps at the City Deep, Bantjes, Modder B, and Brakpan, all new producers in 1911, who were able last year to add materially to their output as well as to the grade of ore sent to the mills. If there is one feature of Witwatersrand mining to which attention ought to be drawn, it is the growing importance of that section of the Rand north and east of Boksburg, and known as the Far East Rand. It is only two years ago that attempts were made, on unorthodox geological grounds, to show that the mines in this area were off the Main Reef Series altogether, a theory which received a certain amount of credence in some quarters. This idea has now apparently been abandoned, for today the Far East Rand is not only regarded as a valuable Main Reef area, but one of the most promising future sources of gold production on the Rand. The metallurgical work of the past year is discussed elsewhere in this issue by Alfred James, and the share-market by T. A. Rickard, so this page will be devoted to mining technology.

There is not much that is new to notice with regard to any changes in the method of working. A modification in the ordinary Rand system has been introduced on the flat reefs of the Far East Rand, partaking slightly of the long-wall method of working; but it is too early yet to form a reliable opinion as to whether the strong and rigid hanging walls of the Rand will be able to adjust themselves to this changed method of working. There has, for a good many years, been considerable discussion about the advisability of introducing the long-wall method of mining, or a modification of it, in the flat-running reefs of the Far East Rand, and any tendency in this direction will be watched with interest. The method, described in last year's review, of driving the levels farther apart, and feeding one principal level fitted with haulage, has been introduced at the Crown Mines, and the process of concentrating the underground as well as the surface operations has been concluded during the latter half of the year; but it is still too early to notice any change in the working costs. Since the introduction of coal-mining methods on the Rand, there has been a tendency to use animal and mechanical traction underground to a much larger extent than formerly. As might be expected, universal success and economy have not attended these well meant efforts, because in some cases the underground conditions have not been altogether suited to the new methods; but, where suited, a fair amount of success has been achieved. Mining difficulties continue to increase with depth, and at some of the deep mines 'air-blasts' have been all too common. In the shallower stopes, too, they have taken place where pillars have been left too small or some pronounced line of weakness, such as a dike, has shown itself.

Sand-filling has continued throughout the year and has rendered particularly good service in arresting 'weights' and movements in the neighborhood of shafts, also in the general protection of the surface occupied by buildings, or railways over worked-out stopes. Sand-filling has also been found useful as an aid in the extraction of valuable underground pillars. At the Simmer & Jack Proprietary and several other mines, the use of current sands for filling underground stopes has been extended during the year. The cost of sand-filling on the Rand varies from 10 to 24c. per ton of sand put into the workings, according to circumstances; so that at the lower figure it is about equal to putting sand on to the surface dumps, and it seems strange that sand-filling under these circumstances is not practised even more extensively.

Miners' phthisis has bulked larger than ever in the mining topics of the Rand during the past year, the action of

the Government in introducing compensation and insurance bills bringing the subject into greater prominence than ever. After the withdrawal of what was evidently only a half-considered proposal of the Minister of Mines, legislation was introduced, as a result of careful inquiries, throwing the whole burden of providing for the victims of the disease on the mine-owners and the miners, the Government only contributing a small amount for the relief of mines considered unable to bear the impost, with the object of preventing their closing down. It was anticipated that the compensation would prove a heavy incubus on the mines, but the burden so far has proved much lighter than anticipated. With regard to the compensation bill, it does not seem likely that more than 2000 applications, genuine and otherwise, will be received, and the levy on the mines may amount to $970,000, or say 4c. per ton milled, which is the minimum estimated some time ago that the act would impose on the mines, the majority of the authorities placing the amount considerably higher. With regard to the insurance against miners' phthisis, the outlook is even brighter. The throwing of the burden upon the shoulders of the mine-owners and men, and the greater activity displayed by the Mines Department of the Government in carrying out the mining regulations bearing on the dust question, has produced an almost incredible improvement in the underground conditions on the Rand. The most benefits have been derived from putting into general use the watering clauses of the mining regulations, which in some mines are as well observed as they were neglected before.

THE YEAR IN RHODESIA

By Owen Letchier

The past year has not been a particularly eventful one in Rhodesia. No remarkable discoveries have been made, and there has been no appreciable increase in mineral production. It appears likely that 1912 returns will be a little greater than those of 1911. The situation in the mining districts is at present unsettled on account of the continuance of drought. The rainfall in 1910-1911 was considerably below the average, and the present 'rainy season' has also proved disappointing. The majority of the rivers and ponds on which the mines of the country are dependent for water are dry, and numbers of mills have had to be closed. Unless good rains fall soon, numbers of larger and more important mines will be compelled to restrict their output and possibly hang up stamps altogether. It is therefore difficult to estimate production for the final months of the year. For the first nine months, the gold output has amounted in value to £2,032,677, and the output of other minerals (coal, chrome, iron ore, lead, silver, and asbestos) to £187,028. In 1910 the gold output for the full twelve months was worth £2,568,198, and other minerals £222,930. For the twelve months of 1911 the figures were: Gold, £2,647,895; other minerals, £242,864. Unless the drought has a widespread and damaging effect before the conclusion of the year, the 1912 return will probably be in the neighborhood of £2,650,000 for gold, and £250,000 for other minerals, a total of £2,900,000. Rhodesia will, therefore, probably again figure as sixth on the list of the world's gold-producing countries with a contribution of slightly under 3% of the total and ranking inferior to the Transvaal, the United States, Australia, Russia, and Mexico.

Just as there has been but little expansion or contraction of production, so too the aspect of the industry as regards profits has remained unaltered. The high cost of living combined with the fact that the miners are scattered and but few properties are of a nature favorable to operation on a large scale, have militated against efforts to reduce working costs, and, since there has been no appreciable advance in yield per ton milled, the profits earned have been about the same as in the preceding year. A large number of Rhodesian ventures are small privately owned or leased mines, and it accordingly is impossible to estimate with any degree of accuracy the total profit secured. At a very rough approximation, however, the gross earning may be placed at between £900,000 and £1,000,000 for the twelve months. The Globe & Phoenix, Eldorado, and Giant have each distributed substantial sums among shareholders, and a new dividend-payer in the Lonely Reef has entered the list. Development has proceeded satisfactorily and, taken on the whole, has been gratifying. At the Shamva mine (a large 4 to 5-dwt. deposit under 'Gold Fields' control in the Abercorn district), 2,141,992 tons of nearly 5 dwt. value had been developed at the end of June, and at the Cam & Motor mines (Gatooma area) about one million tons of ore of 10 dwt. value per ton has been blocked out. Both these mines are expected to commence milling operations next year and to pay dividends at an early date. In addition to the Shamva and the Cam & Motor, the Falcon (a gold-copper venture in the Blackwater district) and the Antelope, to the southwest of Bulawayo, are being equipped with crushing plant and should commence drilling within the next nine or ten months. While developments in these ventures have been highly encouraging, there have been two or three severe disappointments. The Jumbo mine virtually has exhausted all its profitable ore. the Giant Mines Co. has not yet found the lode in the lower levels, and apparently the underground position in the Eldorado Banket mine is less satisfactory.

An improvement in native labor conditions has been witnessed. The Labor Recruiting Bureau has organized in a most creditable manner; so much so that the rather unusual development of supply exceeding demand was announced a month or two ago. As usual, a large amount of prospecting has been carried on all over the country. Several small and rich quartz shoots have been found, but apparently no new deposits of much promise have been opened. The Geological Survey has continued its labors, and a number of reports have been issued—mainly, it is to be regretted, of purely scientific value.

As regards minerals other than gold, the bulk of the production has been derived from the Wankie colliery and the chrome iron deposits near Selukwe. At the colliery coking ovens are built and it is intended to furnish coke to the Katanga copper mines. Large quantities of chrome iron ore of good quality have been shipped to Europe, but the high freight charges render the margin of profit small. The cassiterite discoveries on the Victoria area of Mashonaland have proved most disappointing. On the other hand, a highly promising occurrence of tin stone is being opened to the east of Salisbury by an influential Johannesburg syndicate. In regard to copper ores the Umkondo mine near the Sabi river is being opened again and work at the Edmundian on the Rhodesian-Portuguese frontier has been resumed in a small way. The English law courts finally decided in favor of the De Beers Corporation in the case of De Beers *v.* Chartered Co., and thereby established the right of the great Kimberley corporation over all the diamondiferous areas in the country. The deposits so far discovered have therefore remained inactive. Altogether 1912 may be characterized as a year in which the rates of production and profit-earning have been maintained, while development has been pushed and foundations for the building up of a more prosperous industry have been laid. That, I think, is the sum total of Rhodesian endeavors in the field of mining during the past year.

AUSTRALIA

The past year's work in this country has been one of much interest from several points of view. The drought, which had interfered with the previous year's agricultural industry and threatened to do so again, was not felt so severely as anticipated, and the season should show an increase in mineral production. A great deal of gold was exported, which fact was argued by many to be a bad sign; and the finances of two of the states are in poor condition, one from too much borrowing, and the other from continual deficits resulting from its general internal condition. The Federal Government has, on the whole, done fairly well in its administration, and the most important work undertaken was the starting of construction of the transcontinental railroad, which will be 1060 miles long and cost about $18,000,000. This Government also started a public savings bank. The country has rich iron deposits in sev-

eral states, and, stimulated by the large imports of iron and steel goods, increased railroad construction, and shipbuilding, the Broken Hill Proprietary is erecting works on a large scale at Newcastle, in New South Wales. Gold production showed a further decline. On the other hand, the continued high price of metals was felt in all the metal-mining districts. Several new goldfields promised well for a time, but nothing is heard of them now. The following table gives the approximate gold output from the various states, those from South Australia and Tasmania being estimated:

	1911. Fine oz.	1912. Fine oz.
New South Wales	181,121	165,000
Queensland	381,845	354,000
South Australia	11,000	9,000
Tasmania	32,992	30,000
Victoria	503,541	447,000
Western Australia	1,370,867	1,270,000
Total	2,481,366	2,275,000

In New South Wales, interest has centred on Broken Hill, which place is quite prosperous and has been practically free from labor troubles during the year, although would-be agitators have tried to stir up strife. The water-supply is also in safe condition, and will be augmented according to Government plans under construction. The South and Central mines have opened in a satisfactory way, and the Proprietary decided to work two shifts underground. The flotation plants have treated large tonnages of old tailing, and paid dividends, while metallurgically, general results from the complex silver-lead-zinc ores have been good and promise to be better. Mt. Boppy is the chief gold mine in the state, and its plant has been under reconstruction. There was excitement for some weeks over rich specimen ore in the Long Tunnel mine in one of the southern districts. The Great Cobar copper mine is improving its position, and, besides the smelters, a concentration plant has been built. The coal production of Newcastle maintains a high tonnage and should increase.

Each state has its great centre, and Queensland directs a keen eye on work at Mt. Morgan. A change of management was effected in 1912, smelting practice altered, and now the monthly output approximates $500,000 in gold and copper. Charters Towers has been struggling hard to find new ore-shoots at depth, and the local people deserve all credit in trying to stop the decrease in gold output. At Gympie, the Scottish Gympie is treating low-grade ore and is to add considerably to its equipment. Otherwise this old field is quiet. Mt. Elliott and Hampden mines have produced copper steadily, and Chillagoe has had a busy but unprofitable year. Queensland is rich in fine gems and rare metals, and the annual output of these is quite important. South Australian mining includes the Northern Territory, which belongs to the Commonwealth Government, but work in that tropical country is unsatisfactory and little is heard from it. Nearly all the mineral production of the former state is from copper, which is produced by the Wallaroo and Moonta mines, which are not opening so well as formerly. At Port Pirie the great smelters of the Broken Hill Proprietary are situated, work here being of an exceptionally interesting character.

In Tasmania the price of metals has made itself felt. Mt. Lyell has been unfortunate in having a fire, and bad fall of rock, which killed over 50 men in all. The North Lyell mine is still producing good ore. A hydro-electric plant is being constructed for the company. Another large hydro-electric plant is being built for another company, which will sell power over a large area and also manufacture calcium carbide. The Zeehan district, with its complex ores, has been quiet, while Mt. Bischoff and the Briseis mines have been crushing and sluicing their tin ores, respectively, with profit.

Working the sidelines of 'reef' at Bendigo, in Victoria, helped production and revived the field generally. The big mine of the year was the Central Red, White & Blue. From a metallurgical point of view, Bendigo is improving slowly. Work on the 'deep leads' was not of much interest. In Gippsland, the well known Long Tunnel mine does not offer much hope, and the complex ore of the Cassilis has led to much management and experimenting. The State Government's coal mine at Wonthaggi has been opened remarkably well and produces a large tonnage of fair-grade coal.

Several new mines in Western Australia have started to yield gold during the year, but the downward tendency of production in the state cannot be checked. At Kalgoorlie, the Associated Northern parent mine is in the hands of tributors; but its Ora Banda property promises to be profitable. This is a low-grade district, and should give a fair account of itself in time. The Associated is making small profits, but development is unsatisfactory. At the Horse-Shoe, the deeper work may help matters in 1913, but the past year has been unprofitable. The Ivanhoe is probably the best mine on the 'Golden Mile' from a development point of view and future prospects, although the grade of ore treated had to be reduced. The Meekatharra field is one of promise, but Paynesville was disappointing. New producers were the Yuanmi, Mountain Queen, and Gimlet South Extended, while the Bullfinch should be operating in a short time. There were many wage troubles in the state, those affecting the mining industry being that of the engineers, molders, and the discussion during the past three months between the Chamber of Mines and the various unions at Kalgoorlie. As the year closed it seemed inevitable that a general strike would occur at Kalgoorlie before long.

NEW ZEALAND

This country had a rather troublesome year, due solely to the stupidity of men who did not know when they were well off, and gold production declined from 411,390 fine oz. to about 330,000. If the mining industry of this little Dominion suffered, its agricultural pursuits were not affected, and they will continue to expand with such rich soil and good seasons. Labor conditions, or rather the attitude of labor toward general mining operations, was one to be remembered and the most productive districts in both islands were at a standstill for several months. Through the firmness of the mining companies, the thinking people, the free workers, and the Government, a stage has been reached where conditions will probably remain peaceful, and the gold yield may be expected to return to usual figures. In the Waihi district the trouble arose between two unions, and the companies were gradually drawn into it; while at Reefton the question was one of deciding who should say how many men should work a 'baby' drill. No new goldfields have been discovered or opened in New Zealand for many years, and the prospect is not bright, although there is a large area of mountainous country which has not been thoroughly prospected, even near those districts worked at present.

The Waihi company has seen its best days; but production of gold and silver bullion should continue on a fairly large scale for many years. During the strike, a general clean-up was made, resulting in an output of $240,000, but the bullion from the first run since restarting has been absorbed in the plant. Work on the hydro-electric scheme, to supply mines and mills with power, is well under way, and will cost $750,000. Strikes come hard on mines like the Grand Junction, which had paid one dividend after about 18 years' development. The Waihi-Paeroa Gold Extraction Co., which is dredging and treating tailing from the river below the Waihi district, is now dealing with 18,000 tons per month, yielding $30,000 and paying dividends. The old Thames and Coromandel mining centres are very quiet, yet a considerable population remains. Coal-mining also suffered from labor troubles for a short time, but the total production should be about 2,000,000 tons, produced from the west coast of the South Island and the Auckland province. North of Auckland a company is making about 50,000 tons of high-grade cement per year, and is doing well for a local concern. Although mines in New Zealand employ a fair number of men, the industry is small compared with that of farming, and is likely to continue to decline.

MARKET REPORTS

NEW YORK SHARE MARKET

A review of the conditions prevailing in the mining markets of New York during 1912 is inevitably the review of a period of masterly inactivity. The opening of the year just departed saw the much heralded boom in Porcupine showing its first signs of collapse, and the entire year has seen absolutely no mining promotions of any importance, outside of deals made in the 'coppers.' The conditions at Cobalt were such that notwithstanding the fact that 1912 has shown a but partly expected increase over the output for 1911, it has nevertheless been recognized on all sides that the greatest possibilities of Cobalt are now known. Inasmuch, therefore, as the general public is never interested in a mining district except where its possibilities have not yet been revealed, it is not surprising that the Cobalt following has dwindled. It has been continually deplored throughout 1912 that the Mexican situation has been such as to render it impossible to finance anything in the way of a Mexican mining enterprise. The improvement in the price of silver was one for which Mexican mining companies had waited long, and it was a perverse turn of fate that brought with the higher price of the metal the downfall of the Diaz regime, and the apparent inability of the Maderistas to establish an adequate police surveillance of the country.

The really important mining matters of the year took place in copperdom and may be briefly summarized as the concentration of control of the copper industry. Throughout nearly the whole of the year of 1911 there was much talk of a copper merger which was to embrace the properties controlled by the leading groups, and it was at one time stated that everything had been prepared for offering to the public shares in a copper company to be second only to the United States Steel Corporation; that steps had been so far taken as to have certificates all completed save attaching of signatures. This flotation was finally abandoned on account of the increasingly hostile attitude of the law department of the Federal Government. Early in 1912 the formation of the present Inspiration Consolidated Copper Co. was completed, and as a result there sat down around one directors' table representatives of all of the copper producers of first magnitude in the United States. Finding that legal obstacles blocked the formation of a copper merger as a distinct entity, the copper producers succeeded in arranging a most effective but intangible combination indirectly. It can be said with a fair degree of certainty that were a copper merger to be completed its board of directors would in all probability vary but little from that of the Inspiration Consolidated. The list includes Thomas F. Cole and John D. Ryan, the latter now recognized as the working head, while the Cole-Ryan-Amalgamated group of mines includes so many of the best known copper properties that enumeration is hardly worth while. The president of the company is William B. Thompson of the stock exchange house of Thompson & Towle, and who, in conjunction with Mr. Ryan, was one of the principal figures at the various conferences held in New York and in London, as a result of which the differing interests were finally harmonized. Among the directors is Edmund C. Converse, who is one of the principal figures in banking circles in New York, being president and director in both the Astor Trust Co. and the Bankers Trust Co. and a director in the Guaranty Trust Co., which last-named institution is one through which a vast number of the many hydro-electric power plants have been offered to the public. Mr. Converse is ordinarily looked upon as a representative of the Morgan intrests. The United States Steel Corporation is represented on the Inspiration board by its ex-president, William E. Corey, and the Standard Oil Co. by William Rockefeller. The Guggenheim-Morgan interest is represented by Eugene Meyer, Jr., while Phelps-Dodge are represented by the presence of Albert H. Wiggin, president of the Chase National Bank, and Francis L. Hine, president of the First National Bank and a director in the Chase National. The Inspiration Copper Co. may be fairly considered to reflect the close community of interest which has come to prevail in the mining, smelting, and marketing of copper. It was in January of 1912 that the bonds of the Inspiration-Live Oak combination were offered for sale. These securities are now quoted at 105, the high mark during the year having been 110½. The financial weight of the combination began to make itself felt in the copper metal market early in 1912, and by June quotations had reached 17c. The stabilization of the market is apparent when it is noted that during the latter half of the year just closed there has not been a variation of as much as 1c. per pound. The skepticism with which the movement was first greeted, the rumors of hidden stocks of copper, the accusations of blister copper held up at the refineries, were all matters of incidental market news, for the most part treated with obvious indifference by the powers in control. That control having been achieved, and the consumers and producers at a deadlock, the forces on each side avowing a determination to starve the other into submission, it is fitting that at the close of the year there should now be promised another federal investigation. In conclusion, it is worth while to remark that there have been several important accessions to the list of dividend payers among the copper mines, the public has not vouchsafed to the copper share list any proportionate degree of market support. Some particular instances of market-making having been conspicuous, as in the case of Chino, Braden, Inspiration, and some others, but as a whole the public has assumed and maintained an attitude of apathy.

The year 1912 has seen determined efforts to clear the field of mining finance of the makers of dishonest markets, and it is sincerely to be hoped that these efforts may result in better financial methods. At the opening of the year George Graham Rice, whose pyrotechnics have taken up much valuable space in the press of the country, was on trial for using the mails to defraud, his campaigns in Ely Central and other mining issues having finally reached their inevitable collapse. Rice eventually pleaded guilty, served his sentence, and is again at large. At the close of the year there is in progress a trial of a similar nature where, however, the principal figure among the accused receives an infinitely greater degree of sympathy. For some weeks the prosecution of Julian Hawthorne and his associates has been in progress. The son of one of the great figures in American literature, and himself a literary man of no small talent, Mr. Hawthorne appears to have lost his bearings entirely in the marketing of the shares in so-called Canadian mining properties, which properties appear to have been, as a matter of fact, landscapes solely.

A review of the events of the year includes the incorporation of the Ray Central into the Ray Consolidated, the enlarged property being looked upon as second only to Utah Copper in its possibilities. The Tonopah district acquired a new leader in Tonopah-Belmont which, as result of a long period of development, came into its own as one of the greatest silver mines of the world. The early part of the year saw the final collapse of some of the promotions in Guanajuato, Mexico. The assets of the Securities Corporation, Ltd., were sold at auction. In this corporation were shareholders all over New England and the Middle Western states, comprising one of the best groups of people ever brought together in a mining enterprise not dominated by Wall Street capital. In the collapse of the Securities Corporation and the collapse of the smaller Development Company of America, the mining industry lost the support of people which it could ill afford to lose. The Development Company of America was best known by reason of its attempt to restore the old Tombstone Consolidated property in Arizona to a productive basis. The activities of the Guggenheim group included a great deal of what was of interest in mining during the year. Guggenheim shares were distributed in the French market, their interest in the old Esperanza in the camp of El Oro, Mexico, was liquidated, while the development of Chino and Braden Copper into properties of the first magnitude and the acquirement by affiliated interests of the Alaska Gastineau and organization of the Alaska Gold Mines Co., are matters of current news, as is for the most part the

recent strike at Bingham, Utah, and the sympathetic movement at Ely, Nevada.

The copper mining industry lost in April, 1912, its great statistician in the death of Horace J. Stevens of Houghton, Michigan, whose 'Copper Handbook' had grown from the size of an old-fashioned McGuffey's Third Reader in 1901 to two bulky volumes in 1912, which have not even yet gone to press. Mr. Stevens was a man of great originality and of untiring industry as such a compiler must be; his most engaging characteristic was his ability to make terse and expressive comment concerning those companies which he believed to lack the element of good faith. At times his denunciations could well be described as eloquent.

In the mid-year there was completed in New York a rather formidable organization, known as the Canadian Mining & Exploration Co. with a $5,000,000 capitalization in shares at par value of $5,000 each. The directors include Percy A. Rockefeller, William E. Corey, J. R. DeLamar, Ambrose Monell, and Sir William MacKenzie. The concern was promoted, for the purpose of taking over, financing, and developing meritorious mining enterprises, but whatever its activities may be have since its organization, they have been accompanied by no public announcements. In October the followers of copper in Boston, and this includes the greater number of its citizens, received a very severe jolt, that is if Boston could be said to recognize anything so vulgar as a mere 'jolt,' in the failure of the Dow promotions. The companies concerned appear to have withstood the shock and development at the Franklin, Indiana, and North Lake mines are proceeding as originally planned.

Mines and mining to the eastern mind are, outside of the Engineers' Club, connected with financial and market operations almost invariably. Along this line of action 1912 has accomplished as nearly nothing as could well be done in any similar period of time. The year saw the culmination of a wild ballooning in wireless issues, it also saw a quiet boom in the shares of public utility companies, of industrial issues, and hydro-electric properties—but in mining little or nothing was done. It is only fair to say in conclusion that with better methods and elimination of undesirable elements great improvement in this direction may be expected, and that with these things accomplished the industry may be assumed of assured of hearty public support.

LOCAL METAL PRICES

San Francisco is not a primary market for the common metals except quicksilver. The prices quoted below therefore represent sales of small lots and are not such as an ore-producer could expect to realize. Ore contracts usually call for settlements on the basis of Eastern prices, less freight and treatment charges. The prices quoted are in cents per pound, except in the case of quicksilver, which is quoted in dollars per flask of 75 pounds.

San Francisco January 2.

Antimony	12—12¾c	Quicksilver (flask)	38.50
Electrolytic Copper	18—18¼c	Tin	52—53¼c
Pig Lead	4.60—5.55c	Spelter	8¼—8¾c

Zinc dust, 1400 lb. casks, per 100 lb., small lots $9.50—9.75; large $7.50—8.50

METAL PRICES

(By wire from New York.)

NEW YORK, December 31.—Copper prices are firm with active buying for early shipments. American consumers are showing more interest in the market. Lead is firmer and a considerable volume of business has been done at somewhat better prices. Spelter remains unchanged. Average daily prices for the past week, in cents per pound, based on wholesale transactions, standard brands, are given below.

Petroleum Production of California

Final figures for the month of December are not available, but the total gross production for the first eleven months of the year is shown below with details for January and November. It will not be far wrong to assume that December production equalled that for November, in which case the total for the year would be 90,615,194 barrels. This shows an increase of 8,000,000 bbl. Complete figures for the United States cannot yet be given, though on other pages the Illinois, Midcontinental, and Gulf Coast figures, all showing decreases, are quoted.

STEEL MAKING on a large scale in Canada is foreshadowed by the announcement that the United States Steel Corporation will build at Sandwich, Ontario. With blast-furnaces running to capacity and unfilled orders equivalent to three months capacity, new works are inevitable, and trade makes light of international boundaries.

REFORM is searching out the hidden corners in New York, and the Stock Exchange is seriously considering radical changes. It is certainly anomalous that in these days of rapidly increasing public supervision an institution that so vitally affects the whole people has been left to its own devices. Possibly there is a connection between ventilation of the known abuses and the disinclination of the public to 'trade.'

QUICKSILVER enjoyed a prosperous year in 1912, as related by Mr. Clifford G. Dennis in our review number. An unfortunate error in our draughting room lead to transposition of lettering on the curves of production and price used in illustrating his article and appearing on page 61. The price for the year closed at about $40 per flask, as shown by figures in the article itself, and not $20, as the curve indicated.

LOSS of the Government suit against the Canton Mining Company, wherein application for patent to mineral claims in the bed of the North Fork of Feather river was contested on the ground of the land being non-mineral and probably desired for water-power development, seems to indicate, as maintained by Mr. W. C. Mendenhall, that the United States Land Office favors the miner where the evidence warrants.

GOLDFIELD, as shown by the report for December, is pouring out a lessening stream of gold, and the time has come when the company owning the great bonanza must seriously consider treatment of low-grade copper-bearing ore. It will be remembered that Mount Morgan, in Queensland, changed from gold to a copper mine, and at Butte copper replaced silver in depth. What may prove true at Goldfield is still uncertain, but all will join in the hope that the analogies cited prove good in Nevada.

FOREIGN money involves difficult calculations by both travelers and those who stay at home. In Peru the standard coin is the pound, divided into 10 soles of 100 centavos each. The Chamber of Commerce and Exchange has just adopted a standard form for written expressions of Peruvian currency. The pound is to be indicated by the abbre-

viation Lp., and periods are to be placed between the figures representing pounds, soles, and centavos. When a number includes pounds only, the figures are to be followed by a period and a dash; thus, Lp. 10.—. Commas are to be used as in the United States, to point off integral fractions. The expression Lp. 10,250.8.15 would be read 10.250 pounds, 8 soles, 15 centavos. Such efforts to clarify writing are highly to be commended, though we join *The West Coast Leader* in protesting at the substitution of Lp. for the familiar £ used for the British pound, which has the same value as that of Peru.

ELECTION returns are not always conclusive where the vote is at all close until the final counting of the ballots, and the apparent victor on the day after election may prove to be the loser in the end. Comment has been widely made upon the amendment to the Colorado constitution by which mills and smelters were defined as public utilities and put under the regulations governing such utilities. Final certification of the returns indicates, however, that the amendment failed of passage. In this we believe the state to be the gainer. Whatever possible advantage might have accrued from the power to regulate the rates of large smelting corporations, there can be little doubt that the law, which applied to all mills, would have interfered to some degree with the operation of small producers: the very ones which need most to be encouraged. We assent to the general principle that the state should supervise the industries carried on within its borders, but supervision may easily be extended beyond the limit of profit.

MINE inspection is to the fore again in California, and several bills have been prepared for introduction at Sacramento. This state is almost the only one remaining in which there is no inspection of mines by a state officer. A bill making provision for such inspection of mines was passed by both houses of the last legislature, but being considered defective, failed of signature by the Governor. We believe that state inspection of mines is a wise and necessary measure, but having waited so long California may well take time to formulate a really good system. Most important of all is to provide for non-political appointments and for pay and authority ample to attract high-class men to the service. The operators can have no fault to find with mine inspection if honest and competent men be appointed. We believe that they have as much to gain by impartial inspection of their works as have the men. Practically all users of boilers carry special insurance on them, and it is well recognized that the most valuable feature of boiler insurance is the inspection. In Illinois the coal operators organized a mutual insurance company to carry their indemnity risk, and they have found that the periodic inspections made by competent men on behalf of the insurance company, are worth the whole cost of the insurance. That official inspection in some states has been worthless is a result of defective laws and the making of political appointments. Inspection itself is good and should be welcome.

Flotation Methods

Adoption of flotation for the recovery of copper from its ores by the Britannia Mining & Smelting Company, Ltd., operating in the New Westminster district of British Columbia, as announced by one of our advertisers in another column, is evidence of the rapid progress recently made in the application of flotation to the recovery of copper. The highly successful results attained at the Braden mine, in Chile, where the plant employing the Minerals Separation, Ltd., process makes a greatly increased recovery, as compared with wet concentration, are already well known, and the adoption of the same process by the Britannia company will, it is to be hoped, yield equally good results. The ore at the Britannia consists of silicified schist impregnated with sulphides of iron and copper, and though the mine has been thoroughly developed and its equipment is good, the refractory character of the ore has militated against profitable operation. Extensive experiments have been made with ordinary concentration and magnetic separators and the final adoption of flotation is the result of long and careful study. It is reported that the present 400-ton mill will be altered to a flotation plant and that later a 1000-ton flotation plant will be built. Oil flotation for copper ores is of the greatest importance, because of the high recovery thus made from slime, the bugbear of ordinary wet concentration. The work of the new plant will, accordingly, be watched with unusual interest. The final instalment of the admirable review of ore-dressing progress, by Mr. H. S. Munroe, deals with flotation methods in some detail. Perhaps the essential characteristics in the various processes employed for this purpose can be more clearly brought out by suggesting an alternative method of classification to that employed by Mr. Munroe. Thus the processes may be grouped as follows: (1) Oil rafting, or bulk flotation, where the oil, through its lighter specific gravity, is made to bear up a certain amount of included sulphide. This may or may not be modified by the use of gas bubbles, and forms the basis of the Everson, Elmore, Kirby, and Wolf patents. (2) Granulation by oil, in which the oil is employed to cause the sulphides to cohere in aggregates which will fall in a rising current of water, as in the Cattermole and Minerals Separation patents. (3) Froth flotation by chemical reaction without use of oil, as in the Potter and Delprat processes. (5) Film flotation, with or without the use of oil, as in the McQuisten, Minerals Separation, De Bavay, and Wood processes. (6) Agitation froth, secured by the combined use of oil and agitation. The theoretical principles of flotation are interestingly set forth in the recent valuable book on this topic by Mr. T. J. Hoover, and we are promised an elaborate study of the principles of concentration processes which employ surface tension, in a forthcoming volume by Messrs. H. L. Sulman and H. F. K. Pickard, who are entitled to speak with authority. Meanwhile the application of flotation methods is making progress that is of enormous probable benefit to the mine operator. It is to be hoped that news will henceforth be less concerned with the progress of litigation and more with practical results.

Federal Administration of the Public Lands—II

By W. C. Mendenhall

*Lands valuable because of their metalliferous deposits are not affected either by the withdrawal act or by the creation of National Forests. It was specifically provided at the time of the creation of the latter that location and entry upon mineral claims should continue precisely as though the reserves were not in existence. In the act of June 4, 1897, occurs the clause.

It is not the purpose or intent of these provisions or of the act providing for such reservations to authorize the inclusion therein of land more valuable for mineral therein or for agricultural purposes than for forest purposes * * *. Nor shall anything herein prohibit any person from entering upon such forest reservations for all proper and lawful purposes, including that of prospecting, locating, and developing the mineral resources thereof; Provided, That such person shall comply with the rules and regulations covering such forest reservations, * * *.

Under the law and under the regulations that have been prepared in pursuance of law, miners have full access to the National Forests. They universally exercise the rights which this access gives them, despite the statements that are made to the contrary. Since, however, the administration of the reserves is not within the jurisdiction of the Department of the Interior, except when questions as to patent or other alienations of lands arise and a representative of the Department of the Interior therefore does not speak with authority on forest administration, I shall quote from officials of the Department of Agriculture on the question of miners and the National Forests. H. S. Graves, the Forester, in an address delivered before the American Mining Congress at Spokane during the latter part of November, said:

A * * * charge is made that National Forests are blocking mineral development. * * * The statement that the prospector is interfered with is not true. He is absolutely free to prospect where he will in the National Forests. * * * The only restriction that is placed on him is that he shall be careful of fire. * * * I have repeatedly asked for specific cases where it was claimed prospectors were interfered with. Usually the statements have been general, and those making them could not tell me of any specific instances. In the instances where I have had definite cases given me, I have found either that a prospector has taken offense because a ranger cautioned him to be careful of fire, or it was a case five or six years ago when the Service was first being organized and the personnel was not as efficient or did not understand our instructions as well as now.

Another charge is that when a mineral claim comes up for final proof the Forest Service needlessly and with inadequate information protests it to the Land Office, often holding up patent without cause. My answer to this is that no adverse report ever goes to the Land Office except from a qualified mining expert, the best I can secure under the law. * * * The interests of the Forest Service in this matter are identical with the interests of the public and of the mining industry itself. If a man has a mine and has complied with the law, he should be given the land with the least possible delay and trouble. If he has not a mine as defined by the law or has not complied with the conditions laid down by the law, the land should not pass from government ownership.

Many of those interested in mining have insisted that when claims come to patent the officers of the Government should not make any field examination to determine whether the law has been complied with. It would seem hardly necessary for me to call attention to the reason why such examinations are necessary. The fact is that over and over again the liberal mining laws have been fraudulently used to secure title to land desired for other purposes than mining. I have taken occasion during my incumbency in office to look up this very question and have been amazed by what I have learned. I have specific instances where the mining law was fraudulently used to secure very heavy timber for speculative purposes, to secure sites for water-power development, * * * to secure water holes to give control of extensive stock range, to secure control of valuable areas for summer resort development, to secure areas controlling valuable rights of way for speculation, and various other purposes. Can anyone go before the country in the name of the mining industry and ask that the Government be prohibited from undertaking to prevent such frauds? Does anyone who has the real interest of the industry at heart acknowledge that the enforcement of the mining laws is not the very thing which will protect it from the blight of the wild-cat promotor who has already often enough brought discredit upon it? Let me cite the opinion of the local county mining congress which met at Yreka, California. One of its resolutions urges as follows:

'*Be it Resolved*, that it is the sense of this Congress that the National Forest policy and service has proved an efficient agency, not only in preserving for the prospector the undiscovered mineral deposits in the district, by preventing their acquisition through non-mineral entries, but in facilitating their location, enjoyment, and patenting by good faith mineral claimants in accordance with laws passed in the interests of miners.'

* * * In the National Forests the miner or prospector has the full right to the timber on his claim for the purposes named in the law. If he needs more he can get it without charge through the liberal free-use policy of the service. This policy of free-use is applied with great liberality to prospectors. Thus it is well understood that in case of need for timber off the claim which can not be foreseen, a permit is not required but the prospector is allowed to cut and use such timber as he needs, with the understanding that he will later on notify the ranger regarding the amount taken and its location. Where his mine has become a productive one, and further timber is needed, it may be secured at reasonable prices. In other words, the Government gives him timber and all he needs until his mine begins to yield ore for the market.

This subject of mining claims in National Forests is discussed somewhat more specifically by the Forester in his Annual Report for 1912. I again quote at length:

Mining claims are perfected and new mining claims initiated (in the forests) under the same laws which apply on the unreserved public domain; and no restriction of any kind is imposed on the prospector in his search for valuable minerals. He may go freely where he pleases, and except on the small areas withdrawn by the Government for its own use in administering the forests, may stake out his claim wherever he finds indications that seem to him worth following. If he desires to build a cabin on government land not included within the limits of his claim, he is given a free occupancy permit and free timber for its construction. On his own claim he need only comply with the law to remain in undisputed possession as

*Continued from p. 34.

long a time as he may desire before making final proof. Both the timber and the forage on it are reserved for his use in so far as he may need either in connection with the development of his claim; and if the supply on his own claim is not sufficient for his needs, free use of National Forest timber within reasonable limits and of range for his work animals may be had for the asking. When he desires to make final proof no requirements are imposed upon him other than those laid down by the general mining laws for all public lands. Moreover, by the protection which National Forest administration affords against fire and by the provision made for permanence of timber supplies for local needs, he gains both in security against fire loss and insurance against the danger of having to bring timber from distant markets at a heavy cost in order to work his mine.

Yet the charge is frequently made that the National Forests are closed to mining development and that restrictions have, without legal warrant, been imposed upon the patenting of mineral claims within them.

In so far as these charges are not the result of misapprehensions or misrepresentations, they arise from the fact that before claims to land within National Forests are patented they are examined by forest officers and reports upon them are submitted to the Interior Department, which has sole jurisdiction over all questions of land title. These reports are made in accordance with the request of the Secretary of the Interior and under authority of an express provision of law. Doubtful claims bearing evidence of fraud or failure to comply with the requirements of the mining laws, are always examined on the ground by a practical miner or mining expert and adverse recommendations are made only when such officers certify to the *malafides* of the case.

In reporting upon mining claims the question first considered is whether the patenting of the claim will in any way affect adversely the interest of the public in the land for National Forest purposes. If the claim is not located on land which is valuable for its timber or of high value for purposes other than mining, the good faith of the applicant is taken for granted, if bad faith is not apparent, and the question whether or not the mineral law has been fully complied with is not raised by the Forest Service. The claim is reported upon favorably as not prejudicial to National Forest interests, leaving further consideration of it to the General Land Office on the basis of its customary requirement of proofs in the form of affidavits offered by the claimant and his witnesses.

When, however, the examination of the land by the forest officer develops the fact that a public interest is involved because of the value of the land for national forest purposes —that is, for the present stand or permanent production of timber, the protection of waterflows, use for water-power development, or some other form of occupancy under special-use permit, or public use—a favorable report is made to the Land Office only after it has been shown that the requirements of the mineral law have been fully complied with. Adverse reports on the ground that the requirements have not been complied with (the only ground, of course, on which any claim is ever reported adversely) are never made unless the claim has been examined by a mineral examiner * * * or by a practical miner competent to pass upon the questions involved. Further, before an adverse report is transmitted to the Land Office the showing of facts made by the examiner is scrutinized, with reference to the evidence submitted and the law involved, by the district assistant to the solicitor of the Department of Agriculture; and only if this officer is satisfied that the evidence offered is sufficient to prove failure to comply with the mining laws is the chief of field division of the General Land Office notified that the Forest Service desires to protest the claim.

Such notification is in no sense a rejection of the claim. It merely places before the Land Office the facts as found upon the ground by the examining officer, and the conclusions which the Forest Service believes to be warranted by them. The commissioner of the General Land Office decides, with the evidence and charges recommended before him, whether a hearing will be ordered. His action is necessarily largely influenced by the recommendation of the chief of field division, but is, of course, subject to review by the Secretary of the Interior.

The General Land Office is, under the laws of Congress, a land court. The objectors to the present procedure practically deny the right of the Government to appear before that court, on behalf of the people of the United States, as against a private claimant to mineral lands, in order to introduce evidence of non-compliance with the law under which the claimant seeks title. It is alleged that because the Department of Agriculture is not refused the right accorded any private citizen to seek cancellation of a claim thought to be illegal, when an adverse interest exists, the mining industry is oppressed and a bureaucratic despotism is permitted to overthrow and displace the law.

To deny the right of the public to its day in court would be to open the door to frauds of every conceivable character. It is an undeniable fact that there is a great deal of valuable land in the National Forests. Land valuable for agriculture is open to entry upon regular classification. The requirement of prior classification makes it impossible to use the Forest Homestead Law as a vehicle for fraud. There is no such restriction placed upon mineral entries; the final report made upon these claims is the only barrier to securing under the mineral laws, by means of false representations, patent to land of untold value for other purposes.

The system of requiring reports on each claim before patent issues is necessary * * * to the preservation and good standing of the mining industry itself. * * *

* * * Many classes of frauds * * * are attempted under the guise of the mining laws. In every case the real miner is the victim rather than the beneficiary. In very few instances are doubtful operations promoted by practical miners or prospectors. A few recent examples will serve to illustrate this very important fact.

A supposedly rich mineral find was made in one of the National Forests, and there was a great rush of people to that vicinity. Indications were favorable to the establishment of a permanent gold mining camp, and immediately people not directly interested in mining, but in other related enterprises, flocked to the vicinity of the new find, and began to establish settlements and places of business. Owing to the topography of the country, there was only one favorable place for establishing a town, and this place was immediately covered by mining locations. These mining claims were immediately placed in the hands of professional townsite boomers, who surveyed the land off into building lots under the guise of mining leases, which leases carried an option of sale. By distorting the purpose of the mining laws to suit their special case, these speculators were enabled to retard, if not actually to prevent, bona fide settlement and the establishment of business much needed in connection with the mineral development of the country. It came out in the proofs regarding this case that the leveling that holders of these mining leases did, who in fact were the actual purchasers of the ground, was construed by the townsite speculators as mineral development, as was also the grading and the digging of cellars. The worst feature was that there was no means whereby the purchasers of these lots could secure an actual title to the land purchased, the deeds being only quit-claim deeds carrying no further obligation on the part of the townsite company or the locators of the claims. There actually exist in Nevada, at the present time, townsites a portion of which are upon mining locations, the validity of which can probably never be established, and the holders of the quit-claim deeds for the surface of these claims will never be able to acquire actual title to the land until the mining claims are held to be invalid, and the residents enabled to proceed to secure title to their holdings under the townsite laws. Here the townsite boomer misused the mining laws.

In another instance a large live stock company purchased the majority of the stock grazed in a certain section of the country splendidly adapted for cattle range, except that water was scarce, the only available supply consisting of small lakes or ponds and small springs. This cattle

company, in order to establish a complete monopoly of the range, proceeded to put mining locations and millsites upon all the watering places, with the exception of two or three which were covered by scrip location. No mineral development was, however, attempted on any of these claims. The locations were upon formations containing no mineral showing whatever, and alleged development work consisted of driving adits and trenching for the collection of water, and in the building of the corrals, tanks, and pipe-lines for the handling and watering of the cattle. Part of these locations were in the National Forest and part without. The knowledge of the situation on the part of the forest officers as to the locations within the forest prevented their patenting, except in one instance in which, for some cause or other, the patent was procured without reference of the matter to the Forest Service. Owing to there being no government officers available to submit reports thereon, all of the locations outside of the forest were actually patented, notwithstanding the fact that there was not the slightest evidence of mineral showing in a single case, the work being done in sandrock barren of any trace of mineral and being clearly intended for water development. In this way title was secured to water holes which gave control of approximately 500,000 acres of valuable range. Here the cattlemen misused the mining laws where there was no one to protest or report.

In another instance a sheep man was occupying and grazing a certain area of range within a National Forest in a country mineralized to some extent, and in which the water supply was limited. Some old placer diggings existed in a certain canyon within the vicinity of a small spring, which placer diggings had been abandoned for years, with the exception of the fact that some Chinamen, when out of anything else to do, would occasionally work the claim for what they could get out of it. The sheep man proceeded to locate a mining claim covering the spring and the old placer diggings, established a shearing or dipping corral, and applied for patent to the ground, claiming as his $500 worth of development the work done by men who had abandoned the claim as not sufficient mineral value to be worth further consideration, and work done by the Chinamen mentioned. Here the sheep man attempted to misuse the mining laws.

Another instance illustrative of purposes or motives that actuate individuals in making mining locations, is shown in a case in which a large power company attempted to procure title to a valuable power site by locating mining claims extending up and down the streams upon which the plant is located. These locations were placer locations, and the mineral alleged to exist in the claims was asserted to be lime, and the claims were known as the "limestone placers." A government expert made examination of these claims and submitted an adverse report. Here the hydro electric power company misused the mining law.

Not far from these last-mentioned claims, individuals made application for the patenting of placer locations, alleging the existence of valuable minerals. The location happened to be within a National Forest, and, under the regulations of the two departments, the Forest Service made an investigation in connection with a representative of the General Land Office, and the following facts appeared: There was no showing of mineral whatever upon the locations except a sort of shale, which the locators alleged had some value for cement-making. In the application for the patent the locators alleged that $1500 worth of work had been done. Investigations showed that all the work that had been performed was in grading for driveways and for building locations, and that it actually amounted to less than $300, at a liberal estimate. It further developed that the locators had incorporated a company for the exploitation and sale of building sites for summer homes, this location being in the mountains within easy reach of a thickly populated section of country, and directly on an electric car line leading from a city of considerable size. Here the dealer in suburban summer homes sought to misuse the mining laws.

Not long since, a large mining company, operating mines just upon the border of one of the National Forests, applied for the purchase of a tract of timber situated within the Forest, desiring and in fact being in actual need of the timber in its mining operations. The local forest officer proceeded with usual preliminaries necessary in making a sale. While he was doing so, it became known in the neighborhood generally that the mining company was making a purchase of the timber on a certain tract of land; whereupon some individuals immediately proceeded to the tract and placed thereon mineral locations, alleging the existence of valuable minerals, and endeavored to compel the mining company to pay them as well as the Government for the timber. Failing in this plan of blackmail, the locators abandoned the claims, admitting that all they wanted was the timber. Here the grafters tried to misuse the mining law and exact tribute from the miner.

In a California case an effort was made by means of mining locations to secure control of the most valuable and important bodies of timber in one of the National Forests. One man, with the aid of two or three others and the use of the names of others, covered thousands of acres of valuable timber land by means of placer locations. The report by government experts and the decision of the Commissioner of the General Land Office held the claims to be invalid because of insufficient discovery and the absence of showing of valuable mineral deposits. Here the timber grabber tried to misuse the mining law.

* * * The men who engage in mining as a legitimate permanent industry have no incentive to evade the law, since they are not limited as to the time within which they must apply for patent, but are at liberty to develop the ground and extract the mineral to any extent, subject only to the mining laws of the state. The miner has no trouble in applying for patent under the mining laws for ground chiefly valuable for mineral. The man who has trouble is the man who tries to secure under cover of the mining laws a townsite, a summer resort, valuable timber land, a water-power site, watering places in the desert, or mineral springs in the mountains. Such frauds in no sense connected with the mining industry, would thrive and multiply if mining claims were not reported upon before being passed.

Whether or not legitimate mining development has been handicapped by the examinations made in the recent years since the making of such examinations began may be judged in the light of the facts that more than four out of every five of the claims examined during the entire period have been reported upon favorably. Usually the fifth claim was not actually a mining claim, but was a power site or some such fraud masquerading as a mine.

Experiences similar to those related by the Forester of attempts to misuse the mining laws or the right of way acts within the Forest Reserves are duplicated in the experiences of the Department of the Interior on the public lands outside the forests.

Many of the objections to the so-called policies of the departments amount to nothing more nor less than a demand that government officers shall sit supinely by and permit the laws to be violated in order that valuable public resources may be acquired in an illegal way. In the language of the Forester—"the real miner is the victim rather than the beneficiary of these unlawful acts." They are not advocated by bona fide miners or by the genuine constructive business man. If such men believe that the laws are wrong they endeavor to secure their revision, but do not devote their energies to attempts to evade them.

There has been much discussion in the press recently and in gatherings like this of certain departmental decisions of which that in the East Tintic case (40 Ld.,.271) is a type, and these discussions have revealed a wide misapprehension of the tenor and

scope of these decisions. I quote from the syllabus of the East Tintic case:

To constitute a valid discovery upon a lode mining claim for which patent is sought there must be actually and physically exposed within the limits thereof a vein or lode of mineral-bearing rock in place, possessing in and of itself a present or prospective value for mining purposes.

The exposure of substantially worthless deposits on the surface of a lode mining claim; the finding of mere surface indications of mineral within its limits; the discovery of valuable mineral deposits outside the claim; or deductions from established geologic facts relating to it; one or all of which matters may reasonably give rise to a hope or belief, however strong it may be, that a valuable mineral deposit exists within the claim, will neither suffice as a discovery thereon nor be entitled to be accepted as an equivalent thereof.

It has been loosely stated that this and other decisions of similar tenor have constituted a new construction of the mining statutes. For instance, the Salt Lake Stock and Mining Exchange recently passed a resolution in which occurred this phrase:

Whereas the Department of the Interior by these decisions, revolutionary in their effect, has announced that it is no longer sufficient for the locator of a lode mining claim before securing patent to discover mineral-bearing rock in place, but that such locator must prove that ore of commercial value exists within the limits of each and every claim before the department will pass such claims to patent.

This is a clear misstatement of the department's attitude, and similar misstatements and misconceptions have had wide circulation. The department has said that there must be discovery of a lode possessing "a present or prospective value for mining purposes." This is not holding that there must be discovery of ore of commercial value, but is clearly in accord with the letter and the spirit of the statutes which require that there must be a discovery of a vein or lode containing a valuable mineral deposit. I quote verbatim a recent comment by Mr. Adams, assistant secretary, upon some criticisms which have been made upon these recent decisions.

It has been very frequently asserted that recent decisions of the department require the applicant for a mineral patent to show that he has uncovered ore of commercial grade and quantities. This is apparently founded on a misconception of a statement in the decision in the East Tintic case, which requires the discovery of a vein or lode possessing a present or prospective value for mining purposes. Obviously, this is a very different thing from requiring the exposure of ore in commercial grades and quantities. All that the decision of the department requires is that the vein or lode on account of which patent is asked shall be such a vein or lode as either has present value for mining purposes, or is of such nature as to have a prospective value. In order that it may have a prospective value it is not required that ore of commercial qualities and quantities be exposed, but simply that the vein be of such nature as to lead to the belief that it contains ore worth mining. Obviously there is no justification for issuing a lode patent on a vein that does not either have present or prospective value. Also, obviously, the decision of the department is not a strict construction of the statute, which provides: that "all valuable mineral deposits in lands belonging to the United States" are free "to exploration and purchase." That declaration of the mining law is the foundation on which all mining patents are issued.

The officers of the Department of the Interior recognize, as have all students of our mining laws, that these laws are not perfect, and that they may well be amended to the great benefit of the mining industry. For instance, the law at present does not create any rights in supposedly mineral land except after discovery. Mr. Fisher suggests that the law should be so amended as to give the prospector for a term of years an exclusive right of possession for prospecting purposes within a limited area. If discovery were made within the time given, patent should issue. Meanwhile, the prospector should be obliged to perform a reasonable amount of work during the life of the permit in order to make evident his good faith in attempting to find mineral within the limits of his claim. Such a change would mean the recognition under the federal law of the possessory rights prior to discovery, of which the federal law now takes no cognizance. I presume that no argument is needed before this body to convince it of the advantage of making its filings before federal officers and having them of record in the department which is charged with jurisdiction over the public lands. Such a clause would amply protect the miner during a period sufficiently long to enable him to make those deep explorations that are sometimes necessary in order to make the physical discovery of actually or prospectively valuable mineral which has been required by the law since the earliest mining days in California. This provision appears to be fundamental to American mining customs and practice and I presume that no substitute for it is to be seriously considered.

Let me repeat in closing that the executive departments are charged with the complex task of administering the laws enacted by Congress. They are in this respect the agents of the law-making body, which in turn is your agent as well as that of all other citizens. If you believe that the laws are wrong it is your duty to endeavor to have them changed; it is your duty and it is not to the interest of your industry to engage in the futile task of opposing their enforcement so long as they remain upon the statute books, nor in attacking the officers who are engaged in that enforcement. I believe that the officers of the government who are performing this task, faithfully and disinterestedly, are the best friends of the prospector and the mining industry as a whole. By protecting the public domain from illegal alienation, it remains available for acquisition as the laws direct, and the mining laws provide what to you are the most important of these methods. It is beside the point to state that the departments by their decisions and the bureaus by their regulations are making laws or modifying laws. Regulations are still all in accord with and authorized by the law. Statutes lay down the principles. The details of procedure along the lines of these principles are supplied by the regulations. This, and this only, is their function. Departmental decisions, like court decisions, are interpretations of points in the law about which citizens disagree. So long as there are disagreements as to the meaning of a statute there must be an authority to determine what that meaning is. Without such an authority there is no settlement of the point at issue and anarchy results. The Secretary of the Interior and those who aid him are wholly impartial. They have no interest except in the correct settlement of the questions.

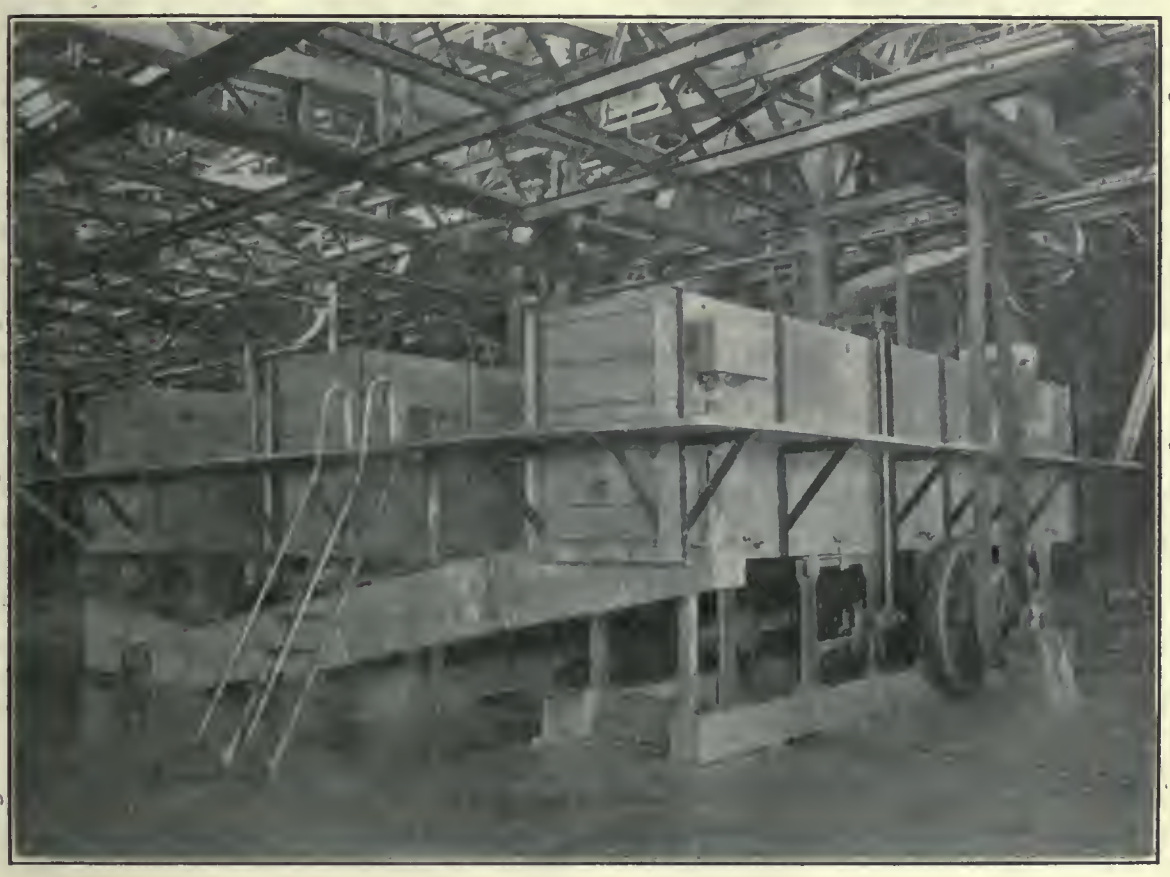
Progress in Ore Dressing

By Henry S. Munroe

Jigging

*Jigging practice tends toward the use of jigs of large capacity designed for the treatment both of sized and unsized material. The Hancock jig is replacing the old Harz jig in the larger mills in the lead and zinc regions of Missouri, and is finding increased application in other parts of the country. The new Doe Run mill No. 3, at Rivermines, Missouri,[31] has now four sections, each having a capacity of about 800 tons, and containing two Hancock jigs, treating 300 tons each of material sized between 2 and 9 mm., and a third Hancock jig treating re-crushed and sized middling from the other two. The stuff below 2 mm. is classified and treated on Wilfley tables. At this mill[32] the Hancock jigs are supported 18 ft. above the ground on structural steel frames. The dead load is 45,000 lb. The jig tray is also steel, consisting of two 18-in. plate girders 20½ ft. long, made of ¼-in. plate, with 2½ by 3 by ¼-in. angles top and bottom. The screen frames and top slat frames are of wood.

The Leadwood mill of the St. Joseph Lead Co. is equipped in a similar manner, except that the four Hancock jigs each treats its own middling after re-crushing and classification. The old Bonne Terre mill of the same company is to be shortly remodeled and Parsons jigs replaced by Hancock jigs, while the Parsons-Rittinger tables have recently been replaced by Wilfleys. The Federal mill No. 3 at Flat River has been equipped since 1909 with twelve 25-ft. Hancock jigs, replacing 132 Harz jigs. Six of these jigs treat over 500 tons each of material sized between 1¼ and 10 mm., and six treat re-crushed middling over 1½ mm. Hancock jigs do excellent work on low-grade ores, but at the expense of the re-treatment of a large tonnage of middle product, much of which is tailing. On ore containing a large percentage of heavy mineral the work is less satisfactory, and they should be used as roughing jigs with re-treatment of the tailing.



HANCOCK JIGS, FEDERAL LEAD COMPANY.

At the mill of the St. Lawrence Pyrites Co., in northern New York, it has been found necessary to run the tailing of the Hancock jigs over three-sieve Harz jigs with siphon discharge. These jigs serve as a guard, and by their use the loss in tailing has been reduced 30 or 40%. At the Desloge mill, Missouri, of the St. Louis Smelting & Refining Co., four Hancock jigs are supplemented by two Hancock jigs treating the tailing. At the Great Falls mill, Montana, of the Anaconda Copper Mining Co., Hancock jigs are used as roughing jigs only, and their tailing and middling are re-treated. At concentrator No. 6 of the Arizona Copper Co., at Morenci, six Hancock jigs are used in a three-stage treatment, the tailing being re-treated in every case.

*Continued from p. 56, January 4, 1913.

[31] O. M. Bilharz, private communication.

[32] *Eng. & Min. Jour.*, Vol. 93, p. 1177, June 15, 1912.

These examples serve to confirm the statement above.

Some of the defects noted are not confined to the Hancock jig and the middle products from Harz jigs will often show a large percentage of barren material which should have gone into the tailing: while the tailing will contain a considerable amount of middle product which should have been saved. This is largely due to the action of the surface current, which tends to bank up the middle product and lighter concentrate toward the discharge end of each jig, and carry material from one compartment to the other and into the tailing which should be retained. This effect is especially noticeable when the jigs are crowded beyond their capacity. In other words, jigs as ordinarily designed and operated do not accurately classify material unless the difference in specific gravity is large. In every ore, however, the specific gravity varies by insensible degrees from that of the rich mineral to that of the barren gangue, and for satisfactory work it is necessary to separate and save a middle product differing but little in specific gravity from the gangue. If jigs are operated so as to save all of this low-grade middle product a large amount of barren gangue will inevitably be brought into the middling, increasing the work of the re-crushing plant and the cost of treatment. On the other hand, if it is attempted to make a rich middle product a large amount of equally rich material is likely to find its way into the tailing, increasing the loss to an undesirable degree. It is thus evident that some method should be found for perfecting the work of jigs and obtaining more complete and accurate separation of minerals differing but little in specific gravity.

These difficulties are increased when a jig, or other concentrating machine, treats its own crushed middling and is operated in closed circuit. When this is done, such material tends to accumulate in the circuit, crowding the machine at times beyond its capacity and lessening its efficiency. The introduction of rolls, screens, or classifiers in the circuit does not always prove effective. Such closed circuits should always be tested from time to time to determine the amount of material actually in circulation. Even when there is no congestion, closed circuits should be examined and carefully tested to determine how and where the surplus material is escaping.

In the Joplin region a jig of large capacity, the Foust,[33] has been adopted at a number of dressing works. In this jig the sieves are of large area, 48 by 54 in., and sometimes 54 by 60 in. In order to secure uniform velocity of water currents over this large area two pistons are used for each sieve. The two eccentric shafts are joined by a connecting rod so that they move in unison. These large jigs have proved very successful, there being up to the present fifty such plants in the Joplin district alone. The larger size has a capacity of over 700 tons in 24 hours. These jigs are built in five or more compartments and treat unsized material, with re-treatment of the hutch-work on finishing jigs, as is usual in the Joplin mills.

The Woodbury system[34] of jigging has found extended application in the Lake Superior copper region and elsewhere. This system is a development of the method of jigging without sizing, which has long been characteristic of that region, and consists in the use of roughing jigs followed by re-treatment of the hutch-work on finishing jigs. In the Woodbury system the roughing jig is provided with a slime overflow and a separate discharge for the sand tailing, so that the jig serves as a classifier for the preliminary separation of sand from slime, and thus avoids the necessity of installing a separate classifier for this purpose. The roughing jig thus makes five products: (1) Fine sand and slime, including material below 60-mesh. (2) Fine hutch sand from second sieve, which goes directly to sand tables, with or without preliminary classification. (3) Coarse middling from siphon discharge above second jig sieve, which is recrushed. (4) Concentrate from first sieve and hutch. (5) Tailing. The Woodbury system has been adopted by the Calumet & Hecla Copper Co. and has recently been installed in the remodeled Tamarack mill.

The Hooper jig, a new type of vanning jig, has now been in successful operation at North River, Warren county, New York, for a number of years. This jig is described by Richards.[35] It is a one-sieve jig, of the movable-sieve type, which has a pendulum swing at one end and an up-and-down movement by an eccentric at the other. The effect of this combined swinging and vertical movement is to bank the heavier material near the head end of the sieve, and thus effectively counteract the tendency of the feed-water to move both heavy and light material toward the tail end of the jig sieve. When several minerals are in the feed the different heavy products lie in inclined layers, thick at the head end and thinner toward the tail end of the jig sieve. The material treated at North River is garnet with a hornblende gangue, with specific gravities of 3.9 and 3.4, respectively. The separation effected is remarkably good, a clean concentrate and low-grade tailing being obtained at a single operation. The hutch-work of each jig is elevated and fed to the next jig of the series, screening and jigging being done simultaneously. A geometrical screen ratio of 1.5:1 is adopted, the coarsest material treated being ¼ in. and finest 30 mesh, six sizes being made between these limits. The possibility of treating successfully minerals differing but 0.5 in specific gravity, and of doing such work on a one-sieve jig, opens a promising field for improvement in jigging practice and should make it possible to perfectly separate middle products from tailing on the one hand, and concentrate on the other; not only insuring rich concentrate and low-grade tailing at a single operation, but producing at each stage a minimum amount of middle product for recrushing, thus greatly cheapening and simplifying ore dressing operations. It is possible that equally good results may be obtained on other types of jig, but to the present this has not proved to be

true as far as records may be used to determine.

The Richards pulsating jig[36] has been tested at a number of dressing works in different parts of the country. Comparatively few installations of an important character have as yet been made. Owing to the small size of the jig cells, this jig has proved exceedingly sensitive to variations in richness of the feed and requires constant adjustment of the discharge gates. This is more noticeable with the lighter sulphides and with middling. Again, the high velocity of the current of feed-water, the volume of which is increased at each cell by the pulsion water, tends to prevent a sharp separation between the concentrate, the middle product, and the tailing. F. E. Shepard[37] plans to remedy these defects by placing dewatering devices between the several jig compartments and providing separate pulsator valves for each, permitting more satisfactory adjustment of the pulsion and lessening the disturbing effect of the surface current. With these modifications it is believed that more accurate work can be done.

Jigs of reinforced concrete have recently been designed and constructed at Cananea, Mexico.[38] These are ordinary three-sieve jigs of the Harz type. The feed-box, side walls, and longitudinal partitions are 3 in. thick and reinforced by 1½-in. mesh $^3/_{16}$-in. wire cloth. The ends and transverse partitions, which are continued as legs, are made 5 in. thick, and are reinforced in the same manner, but with the addition of ¾-in. rods bent so as to strengthen the legs. After removing the forms, these jigs are painted inside with several coats of thin cement to which alum and potash are added. The cost of these jigs is $145, not including the forms, which cost $138 and which are used again. The original description contains working drawings and many details as to methods of construction.

At the Franklin Furnace mill of the New Jersey Zinc Co. jigs built of cast-iron plates, designed by George C. Stone,[39] have been adopted. The plates are designed so that they can be assembled with water-tight joints without the necessity for machine work. The screen frames of jigs, ordinarily constructed of wood, or of wood with flat steel crossbars, may also be made of cast iron.[40] In the case described by Mr. Rice, the frames are 30 by 42 in. and 3 in. high. The sides and ends of the frame are made 1 in. thick and the longitudinal and crossbars ⅝ in. The frame has 54 openings about 4 in. square. The junction of the ribs, at the corners of each opening, is enlarged and cored to receive a ½-in. square wooden plug, to which the wire screen may be attached. These screen frames are not used with ores having a cherty gangue, as often found in the Joplin region, which requires the usual cast-iron grates instead of wire screens.

Fine Sand and Slime Concentration

The Wilfley table still holds its position as the leading concentrating machine for the treatment of sand, although many modifications of the Wilfley have appeared, some of which have obtained a considerable degree of success, notably the Deister, Overstrom, and Card tables. Another of these, the Garfield table, has been introduced on a large scale at the mills of the Utah Copper Co., the Chino Copper Co., and the Ray Consolidated and other mills under the same general management. This table is provided with high riffles, ¾ in. at one end and ⅜ in. at the other, extending over the whole surface of the table. This construction permits the treatment of large tonnage: 175 tons or more per 24 hours. These tables are used for a preliminary rough separation of concentrate from sand, but make no finished product; the tailing being classified, the coarser material crushed, and this recrushed material subjected to similar rough separation on other Garfield tables, the final separation of tailing taking place only after three such treatments, accompanied by considerable reduction in size at each stage. The concentrate from these roughing tables is re-treated on Wilfley tables in each case, yielding a finished product. The tailing from the Wilfleys treating this rich material is recrushed and re-treated. The introduction of the Garfield tables as roughing machines permits the treatment of large tonnage in each section of these mills, while the re-treatment both of tailing and concentrate secures rich concentrate on the one hand and low-grade tailing on the other. The method is thus similar to the double treatment by roughing jigs and finishing jigs of the Lake Superior copper region and followed in the Joplin mills treating lead and zinc ores.

Gelasio Caetani[41] has shown that middling from a Wilfley table is what he terms a 'counter-classified' product: that is, larger grains of heavy mineral (true middling and some concentrate) associated with smaller grains of light mineral (tailing). Table middling should always be classified and re-treated on separate tables. The tailing from the table which is fed from the first spigot will contain all the material requiring further crushing. The tailing from tables treating the finer classified material will be poor. Sometimes classification may yield a finished product.

C. T. Rice[42] suggests some inexpensive and easily extemporized attachments to Wilfley tables; namely, cleats to throw wash-water along the discharge end and avoid dry spots, adjustable fingers near corner to throw heavy concentrate to end and middling to side, and saw-tooth drip-plates on the discharge end to facilitate division of galena and blende concentrate.

A new table for the treatment of fine slime, the Deister slimer, was introduced in 1908 and has attained wide acceptance and installation on a large scale throughout the country. This table has two shallow slime pools which retain a large volume

[41]Gelasio Caetani, *Mining and Scientific Press*, Vol. 104, p. 495, April 6, 1912.

[42]*Eng. & Min. Jour.*, Vol. 93, p. 1129, June 8, 1912.

of thick pulp under treatment. This pulp is kept in suspension by the movement of the table. This gives opportunity for the settlement of the heavy mineral and its separation by displacement from the lighter mineral. This table is provided with wide channels and with riffles by which the separated mineral is guided toward the discharge edge. The Deister slimer has about the same capacity as a 6-ft. vanner, which is its principal competitor, and has the added advantage of making a middle product and requiring less skill and much less attention for its operation. The repair and maintenance cost is less.

For the treatment of the very finest slime, canvas tables[43] are still retained at a number of large mills. Three-deck Craven slimers are in use at the Steptoe Valley concentrator[44] at McGill, Nevada, and riffled concrete tables[45] were installed a few years ago at the Pinguico mill of the Guanajuato Development Company.

An interesting modification of the canvas table is the Darrow-Hambric concentrator,[46] which consists of a revolving frame 28 ft. in diameter with 6 to 10 decks carrying 21 to 24 small trays, 3 by 4 ft., on each deck. These trays were formerly covered with canvas, but recently asphaltic felt, or wood painted with asphalt paint and sanded, has been used instead of the canvas. It is said that these modifications of the canvas table have proved very successful, and that the ratio of extraction is much better than on the ordinary canvas table. It is interesting to note that the development of blanket and canvas tables has been steadily in the direction of the use of smoother surfaces. Originally brussels carpet, blankets, gunny cloth, cocoa matting, and similar rough material was used, and these are still common on gold-dredges. These rough surfaces have given place to the comparatively smooth canvas, which sometimes is painted, making it still smoother. Now a further step seems to have been taken in the use of a painted and sanded surface on the Darrow-Hambric machine. It has long been recognized by the best authorities on ore dressing that for the successful treatment of very fine material a smooth surface will give higher extraction than a rough surface, the introduction of rough surfaces having been brought about in the attempt to increase the capacity and decrease the sensitiveness of this form of concentrator. This has resulted in large loss of fine mineral by reason of the stronger current required to move the pulp over the rough surface. The extraction ratio in these canvas plants is not often more than 30% and sometimes falls below 20%. The adoption of smoother surfaces is a development in the right direction. Tests which I made in 1889[46a] show an extraction of over 85% in −240-mesh slime on Parsons-Rittinger tables covered with smooth enameled duck. In this connection it is interesting to note that cement-top round tables have been retained in the tailing plant of the Boston & Montana mill at Great Falls, Montana, where they have proved to be the most satisfactory concentrator for treating the very finest material. The Darrow-Hambric revolving frame with its small trays is a step toward a return to round-table treatment.

Some years ago I designed and constructed an 18-ft. round table for the laboratory of the School of Mines of Columbia University, with a conoidal surface of large radius in place of the conical surface usually employed. In this table the curvature has been designed so as to compensate as closely as possible for the reduction in depth and carrying power of the films, of feed-water on one side of the table, and of wash-water on the other, as they spread outward in their flow toward the edge of the table. By this simple modification the conditions of settlement and movement of the pulp on the table are rendered practically uniform and the whole surface of the table is rendered available. In the ordinary conical form the separation takes place on the outer part of the table only, the central portion being so flooded with water that but little effective work can be done. By the use of a conoidal surface it should then be possible to reduce greatly the diameter of round tables and lessen materially both the cost of construction and the floor space occupied in the mill.

A. R. Wilfley has designed a multiple-deck slime concentrator.[47] This consists of 12 light decks, 6 by 12 ft., covered with riffled linoleum, assembled in a heavy tilting frame which is shaken endwise by an eccentric. Each deck is fed with slime, and the operation and adjustment of the whole series is controlled by observing the movement of the pulp on the upper deck. The cycle of operations, lasting about 15 minutes, includes: (1) flowing of slime, the decks being nearly level; (2) washing with pulp water; (3) flushing with wash-water. During the second and third phases the decks are inclined. One of these machines has been tested during the year at the mill of the Miami Copper Co. Its capacity is said to be equal to that of eight vanners operated at equal efficiency. Duplex machines with two units of three decks, operated in alternating cycles, have been installed in a number of mills.

The Deister Machine Co., of Fort Wayne, Indiana, has introduced a new multiple-deck tilting slimer which has had eight months' trial at the Miami concentrator, the results of which have proved sufficiently encouraging to warrant the equipment of one section of this mill with these new machines. Each machine contains six decks, each 10 ft. wide by 12 ft. long, covered with oiled and painted canvas which is coated, while the paint is wet, with 50 to 60-mesh sand. These decks are

pivoted at the centre on transverse axes, and are automatically tilted forward during the spreading of the slime and backward while washing off the concentrate. The capacity of a six-deck machine is about equal to that of four standard Deister slimers. The tailing from the new machines is poor, and the saving is approximately 10% over the slimers. The concentrate has to be re-treated on a Deister slimer, the tailing going back to the tilting tables.

The Allis-Chalmers Co. has introduced the Isbell vanner, which embodies some interesting and novel features in design, tending to increase the efficiency of this type of concentrator. The Isbell vanner is mounted on a heavy transverse axis which carries the operating mechanism as well. The vanner frame, including the belt with its rollers and feed trough, is mounted on two longitudinal steel leaf springs set on edge, extending nearly the full length of the machines. These springs are attached at the middle to the tilting axis and provide an elastic support permitting the horizontal movement of the frame. The new type can be built at about half the cost of erection of the older Frue vanner, and has the additional advantage that the side movement of the belt is in a horizontal plane without the side tilt which accompanies this movement both in the older Frue machines and in the newer suspended vanners. Over 1700 Isbell vanners have been installed since the introduction of this new type. The Ray Consolidated and Chino mills and some of the sections of the Utah Copper Co.'s mill are equipped with this machine.

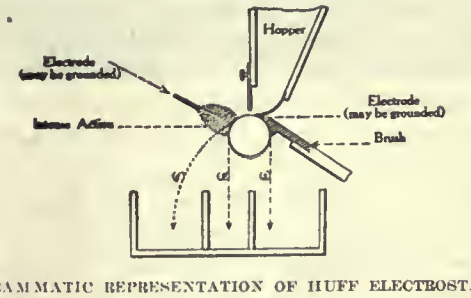
The Peck centrifugal slime separator[48] is a machine operating upon the same principle as a concentrating table in which centrifugal force takes the place of gravity and in which the velocity of the pulp and wash-water currents is controlled by mechanical means. Theoretically, it should be possible to make a separation by the aid of centrifugal force on material too fine to be separated by gravity alone. The Peck machine is the result of many years experimenting and slow development, and has been used on a large scale at Virginia City, Nevada, and at Corbin, Montana, during this time. In the annual report of the Anaconda Copper Mining Co., B. B. Thayer states that experiments with this machine were conducted at Great Falls during 1911 which were successful so far as the concentration was concerned, but that the machine could not be run continuously. He stated further that a new machine will be constructed and tried out in 1912. It is understood that experiments have been made with the Peck machine during the present year at Cananea, Mexico. Should this machine finally prove successful, it will have important bearing on the whole problem of slime treatment, and it may have extended application in the many large mills in which this problem yet remains to be solved satisfactorily.

Magnetic Separation

This method is finding increasing application in the treatment of zinc middling containing iron. Two Colorado mills are described[49] in which magnetic separation is used to supplement mechanical treatment. In both mills a preliminary magnetic roast is necessary. In both cases the Ball-Norton belt machines are in use, in one case replacing a Cleveland-Knowles machine formerly employed. Magnetic treatment has also been applied in Cornwall for the separation of cassiterite from pyrite and wolframite.[50] At this mill a new type of magnetic separator is used, consisting of a solenoid with mushroom-shaped pole pieces between which two feed belts bring the ore into the magnetic field, while the concentrate is removed by an endless-rope drive which serves also to rotate the magnet slowly about the vertical axis.

Electrostatic Separation

The following zinc plants using this process[51] are now in operation or will be during the next month or so: Midvale, Utah, capacity 90 to 100 tons of zinc middling per day; Cananea, Mexico, capacity 40 tons; Eureka, Colorado, Sunnyside Mining Co., 15 tons; Ouray, Colorado, custom plant, 20 tons; St. Elmo, Colorado, Mary Murphy Mining Co., 20 tons. From zinc middling containing 25 to 30% of zinc there is obtained a blende product with 40 to 50% zinc containing small amounts of galena and pyrite and a pyrite product carrying gold, silver, lead, and copper content containing from 7 to 10% of zinc only. The richness of the blende product depends largely upon the amount of gangue present in the middling, the greater part of which goes with the blende. A wide range of sizes is being treated. At one plant the maximum is 2 mm., while at another almost the entire tonnage is through 100-mesh and a large part through 200-mesh.



DIAGRAMMATIC REPRESENTATION OF HUFF ELECTROSTATIC SEPARATOR.

The Wisconsin plant at Plattville ran successfully for several years, but was destroyed by fire about a year ago, just after a complete overhauling and increase of capacity. It is probable that this plant will be replaced soon, but will be situated farther south in order to utilize a larger variety of ores than was commercially possible at Plattville. The Cananea plant has been operating successfully, but is temporarily shut down, due to a change of management. There is also in operation at Buffalo, New York, a plant for removing impurities from artificial carborundum which has been in successful operation for over a year. A plant has recently been shipped

to Australia for the purification of molybdenite. It is probable that in the near future this process will be extended to the treatment of graphite, silver, copper, and iron ores, for which purpose large-scale plants have been planned.

Decrepitation

Decrepitation[52] has been successfully used experimentally for the separation of barite from blende. In each case the material is sized and then brought to a red heat by feeding through a revolving tube, 6 to 8 in. diameter and 6 to 12 ft. long. The blende is not affected, but the barite decrepitates to a fine powder which is easily removed by sifting. The fine tailing contains but a small amount of zinc. This method is applicable to other minerals containing a small percentage of water. In some cases blende has the property of decrepitating and can be separated in this way from pyrite.

Flotation

Separation by flotation is now practised on a large scale in Australia and elsewhere. It is said that one-quarter of the zinc production of the world is now obtained from ore concentrated by this means. An elaborate investigation of the physical conditions determining the flotation of minerals has been made by K. A. Mickle,[53] of Melbourne University, who read two papers on this subject before the Royal Society of Victoria, one in 1911 and a second paper in 1912.

Flotation processes have been developed by a number of inventors, each of whom has contributed something to the process as it is now used, and several different companies are now operating under these patents. The development of flotation methods has been attended with much litigation among the conflicting interests. Without attempting to cover the subject in detail, or to describe the numerous methods in use, they may be broadly classified into four groups: film and bubble flotation, oily scum, and froth flotation. All flotation processes depend upon the surface tension of liquids and on the coefficients of adhesion between liquids and solids, and possibly on similar adhesion of gases to solid particles. Surface tension and adhesion are modified by heat and by the presence of acids. According to Mickle, selective adhesion is affected by the presence of adhering films of carbon dioxide and other gases on the grains of the metallic mineral. This has been denied by other experimenters.

In the film flotation methods, minerals which have a high coefficient of adhesion with water quickly become wetted and sink below the surface. Minerals, on the other hand, which are not readily wetted will float, the coefficient of adhesion in this case being insufficient to break the surface tension of the water. The De Bavay process, the McQuisten process, and the Wood flotation method belong to this class.

The second group depends upon the buoyant effect of gas and air. If gas be generated below the surface of a liquid the particles to which water does not adhere strongly will become attached to the bubbles of gas and float to the surface. The particles to which the water adheres strongly will remain at the bottom, or will quickly break the surface tension inside of the bubbles and sink. The evolution of gas is secured by the action of acids upon carbonates and other minerals, or by conducting operations in a vacuum, which releases the dissolved air and gas with similar effect. The Potter, Delprat, and the Elmore vacuum process depend largely upon gas or air-bubble separation.

The greasy scum flotation group depend upon the strong coefficient of adhesion between metals and metallic sulphides and oil, while the silicate, oxide, and other gangue minerals are less easily wetted by oil than by water. If a small quantity of oil be added to a pulverized mass of mixed minerals, the oil will by selective adhesion attach itself to the former and not to the latter group, especially in the presence of water. Heat and the presence of acid aid this selective adhesion of the oil. By adding more oil the grains of mineral previously coated will be bound and cemented together in a greasy scum which readily floats. The scum also contains bubbles of gas or oil which aid the flotation. The original Elmore process, using thick oils, depended largely on this property.

The froth flotation group depends upon the use of thin oils having good adhesion coefficients but also having the property of forming an emulsion and froth with water and thereby entangling air and gas bubbles. The presence of some slime in the pulp is essential, and heat and the presence of acid are helpful. Among such oils, oleic acid and eucalyptus oil (from the *Eucalyptus amygdalina*) give the best results, although cottonseed oil, pine-tar oil, red oil, and other common oils answer well, especially when mixed with a small amount of oleic acid. The mineral oils seem to possess the necessary properties to a less degree. The Minerals Separation Co., Ltd., has developed the froth flotation process and has recently equipped many plants for its use.

The different processes, however, shade into each other, and it is impossible to assign any one of them wholly to one or the other of the above groups. All of them, except the film flotation group, make use, when necessary, of both acid and oil and mechanical agitation to aid in securing effective flotation. The addition of acid not only releases gas from carbonates and other minerals, but also modifies the adhesion coefficients and surface tension. It is believed that acid has also advantageous effect on colloidal slime. Heat facilitates flotation processes by increasing the effect of acids and also by modifying adhesion. Heat increases surface tension. The most important recent installation is at the Braden mine, in Peru,[54] where three units of 600 tons each have been con-

structed, and the mill will finally be increased to 3600 tons capacity. Over an 80% recovery is made as compared with 61% by ordinary concentration, and it is hoped eventually to bring the recovery to 85%. This ore contains carbonates, and the recovery upon the sulphides is over 90%. At the 1000-ton plant of the Butte & Superior Copper Co. flotation is used for the treatment of blende middling, and is auxiliary to treatment on jigs and tables. A small plant is built and running at the Cuba Copper Co. At the Kamioka mine, in Japan,[55] the zinc middling from wet concentration is re-treated by flotation, using heavy oil in a hot acidulated solution. The temperature used is 80 to 85°C. and the solution contains about 1½% sulphuric acid.

A 60-ton plant at the Kyloe copper mine, New South Wales,[56] has been in successful operation since July 1911. The ore contains 5 to 24% of copper and is concentrated 5 into 1, yielding concentrate of 22.65%, with an extraction of 86.36%. The cost of treatment is 8s. per ton, of which 3s. 6d. is chargeable to regrinding and flotation. This includes a royalty of 6d. per ton. Of the ore milled, 0.67%, or 40 tons per day, is treated by flotation. The Minerals Separation plant and process is used, but without heat or acid. Eucalyptus oil costing 8.5d. per pound is used, 0.65 lb. per ton, making the cost of oil 5.5d. per ton. The paper and the discussion that followed constitute a valuable contribution to our knowledge of the subject.

THE new hydro-electric power plant which the Cerro de Pasco Mining Co. is building at Oroya will be one of the most important in Peru. Power will be generated for the company's metal mines at Cerro de Pasco and Morococha, for the coal mines, the smelter, and the railway company's shops at Oroya.

Goldfield Consolidated Report

The estimated December production of The Goldfield Consolidated Mines Co. is as follows: Total tons mined, 27,946; gross value recovered, $423,000; operating expenses, $170,000; net realization for month, $253,000.

According to the monthly report of J. F. Thorn, superintendent, the total production during November 1912 was 27,775 tons, containing $451,987, or an average of $16.27 per ton, of which 27,402 tons was milled with an average extraction of 92.80%, and 373 tons was shipped of an average value of $19.78 per ton, the net recovery from all ore being $15.12 per ton. The net realization was $250,371, or $9.01 per ton. During the month 3528 ft. of development work was performed. The total cost of mining, development, transportation, milling,

GOLDFIELD CONSOLIDATED MILL.

office, and general expense was $6.11 per ton, distributed as follows:

Mining (including stoping and development)	$3.41
Transportation	0.07
Milling	2.06
Marketing	0.06
General expense	0.49
Bullion tax	0.06
Marketing ore	0.03
Total cost of operation	$6.18
Miscellaneous earnings	0.07
Net cost per ton	$6.11

Considerable new ore was developed in the Combination mine during the month, especially on the second level about 300 ft. northwest of the shaft. The 136BX sill was extended and produced 203 tons of ore averaging $49.20 per ton. The 112X drift on the same level has cut a new orebody and produced 101 tons averaging $36.40 per ton. This new orebody should produce a large tonnage of excellent grade ore. The 210X drift on the third level is being extended to find the downward extension of the

112X ore. The 3-J sill, on the 150-ft. level in the old Sheets-Ish country of the Mohawk, was extended, and produced 170 tons averaging $20 per ton. The 3-P sill being cut on the orebody in 40 drift produced 243 tons of an average value of $16 per ton. The 170-T stope being extended in the orebody cut by the 107-X drift on the 250-ft. level, under the old Sheets-Ish workings, produced 170 tons averaging $21.20 per ton. The 490-R sill on the intermediate between the third and fourth levels, was extended and produced 31 tons averaging $11 per ton. The 490-B sill, on the same intermediate, just north of the 490-R, was extended, and produced 574 tons of an average value of $18 per ton. The 408-I stope in the Clermont has been brought up above the 600-ft. level, and the sill of the 600 produced 805 tons averaging $21.40 per ton. The development work in this mine during the past month has been confined principally to the 1300 and 1400-ft. levels, where some very promising discoveries have been made. On the 1400-ft. level, about 430 ft. south of the shaft, the shale and latite contact was reached on December 7, and since that date the cross-cut has been entirely in latite, well silicified and mineralized and carrying amounts of gold, silver, and copper.

Peruvian Smelting

The fully equipped smelting plant of the Peruvian M. S. & R. Co., at Rio Blanco, which was blown in for a short run about three years ago, was sold at public auction at Lima, on October 26. E. E. Marshall of Lima, was the purchaser for $93,000, the original cost being $576,000. The bond issue under which the plant was foreclosed was $1,250,000. It is said that the plant is ahead of its time, the proper components of a good smelting charge not being economically available at present. Rio Blanco is 83 miles by rail from Callao, at an altitude of 11,306 ft., and 31 miles from Morococha, which is at 15,050 ft., and was to have been the principal source of ore supply. In the province of Cajatambo, north of Lima, and west of Cerro de Paseo, on the western slope of the Andes, are situated the silver and copper mines of S. P. Dunstan, which are producing ore containing 60 to 80 oz. of silver and 10% of copper, treated locally.

Labor Conditions in New Zealand

The principal New Zealand labor unions are once more at peace with the mining companies. Strikes at Waihi and Reefton have been declared off, after having lasted 29 and 25 weeks respectively. The Waihi mine started work in a small way early in October, but the strike continued until the end of November. At Reefton the men will work the 'popper' drills single-handed, but another man will be near at hand to help if necessary. It would be difficult to find in the whole annals of industrial warfare, more senseless or ill-advised strikes. If the Federation of Labor has been beaten, it is due in no small degree to the overwhelming preponderance of moderate opinion among the workers themselves. Lack of public sympathy and condemnation by public opinion, and firmness of the government, has not only prevented the strikes from being successful, but has completely destroyed the power and prestige of the Federation of Labor. During the Waihi strike, the output of bullion from the Waihi and Grand Junction mines was reduced by $2,250,000, and the Waihi Municipal Council, which under normal conditions, has a revenue of $85,000 per year from gold duty, lost about $48,000. Prior to the strike 1500 men were employed in the district, drawing $23,000 per week in wages, so the idle period cost them $670,000, against which only $125,000 was received in strike pay.

Stamp Mill Practice at the Homestake

The table below shows the weight, dimensions, and approximate life of stamp-mill parts in the mills of the Homestake Gold Mining Co., as given in the recent paper by A. J. Clark and W. J. Sharwood on metallurgical practice at the Homestake.

	Material.*	Dimensions.	Approximate Weight.	Approximate Life.‡
			lb.	
Cam-shaft	Wrought iron	5·36 in. diam.	1050 to 1085 †	4 years.
Cam	Chrome steel	2·5 in. face × 35 in., hub 12 in. diam. × 5·75 in.	262	No data.
Cam	Cast iron		256	2 years and up.
Tappet	Chrome steel	9 in. × 12 in.	150	No data.
Tappet	Cast iron		132	20 months and up.
Stem	Wrought iron	3·125 in. diam. × 15 ft.	380 to 390	4 mths. between breakages.
Boss-head	Cast iron	9 in. diam. × 18 in.	236	4 to 12 years; average 6.
Shoe	Special chilled cast iron	9 in. diam. × 8 in.	115	60 to 90 days.
Die	Hard cast iron	9 in. diam. × 5·5 in.	110	30 to 35 days.
Mortar	Cast iron		5500	3 years.
Screens	Cold-rolled re-annealed O.H. steel	9 in. × 50 in. × 0·035 in.	4	10 to 16 days
Plate	Lake copper	4·5 ft. × 12 ft. × 0·125 in.	320	

* Iron castings, with the exception of shoes, which are purchased in lots of several thousand, are cast in the Homestake Foundry, and charged to the various departments at a uniform rate of about 3 c. per lb.

† The shafts in different mills differ slightly in length.

‡ These figures are averaged from a record covering breakages over the whole plant for about three years. At the North-side mills, with lower and slightly faster drop, and somewhat softer ore, the average life of mill parts is considerably longer than in the Lead mills. In the case of chrome steel cams and tappets the period covered by the record is too short to give even approximate data.

Copper Producers' Association Report

The Copper Producer's Association statement shows an increase during the preceding month in accumulation in this country of 19,000,000 pounds.

The changes in surplus since January 1, 1912, have been as follows, in pounds.

	Increase.	Decrease.
January 1912	.....	22,173,252

Review of Australasian Mining in 1912

THE EASTERN STATES

By Our Regular Correspondent

The Australian Commonwealth and its dependencies may, as regards mineral production, be divided into three groups —(a) those areas in which the predominant output is that of gold; (b) those in which gold occupies a prominent but not predominant place; (c) those in which the gold output is relatively unimportant. The first group contains two states: (1) Western Australia, in which 95% of the total value of the mineral production is gold; (2) Victoria, with 87% from gold, and 12% from coal; (3) Papua, with 83% from gold, and 17% from copper; (4) the Northern Territory, with 52% from gold, and 48% from other metals. Despite Victoria's small but not negligible output of coal, and despite the proportion, large in the one case and consider-

THE EASTERN STATES.

able in the other, of the industrial metals in the total mineral output of the territory and of the dependency, respectively, these are all to be described as distinctively gold-producing areas though in all probability the Northern Territory will ultimately become principally a producer of the baser metals. Queensland stands by itself with 45% of the value of its output provided by gold and 45% by other metals, a small 9% coming from coal. The states of the remaining group fall into two divisions, one of them comprising South Australia (with 93% of its total proceeds from minerals coming from the baser metals); and the other consisting of Tasmania, which has a small output of coal, making 10% of its total output, and from which 88% is provided by the industrial metals, New South Wales, of whose output 62% comes from the industrial metals, while the coal output is also large (31%), and the gold small, but not quite insignificant (7%). These three states are then preeminently producers of the industrial metals, while of Queensland's production a large though not predominant proportion comes from the same source. The greatest diversity is shown by New South Wales and Queensland, and the most onesidedness by Western Australia. These facts are worthy of consideration because, in consequence, the appreciation in the prices of metals which has characterized this year's markets has had much more effect upon the mining in certain states than in others. Western Australia and Victoria have been unaffected, while the other states have all benefited considerably. In Queensland there has been much activity in fields that have hitherto 'hung fire' while in the great New South Wales silver-lead field, at Broken Hill, record outputs have been the rule.

The Northern Territory

In making a review of the various portions of the Commonwealth, it may be well to take the least important first. From Northern Territory there is no news. Last year the value of its mineral output was a little under $300,000 and its figures for the current year are not likely to show much change. If anything, there may be a slight decrease. There is reason to believe that there are extensive mineral deposits that will well repay exploitation when the country has been opened and the fields made readily accessible. The territory has the finest navigable rivers on the continent, but is hampered by a trying climate, by its distance from the chief Australian markets, by sparseness of population, and by the lack of railway connection. The Federal Government is under engagement to the state of South Australia, from which the Territory was taken over, to construct a railway line through Adelaide, but it is not showing any undue eagerness to commence operations, realizing thoroughly well that there is no likelihood of the line paying expenses for many years. There is also a scheme for connecting Darwin, the capital of the Territory, with Brisbane and Sydney, by means of a Federal railway to Camooweal on the Queensland border. If that line should be constructed, or even the Adelaide line, there is a chance of the developing of much good mineral land in the Territory which must await scientific exploration until such connection is provided. Next to gold, the principal contributors to the mineral production of the Northern Territory are tin (39%) and wolfram (7 per cent).

Papua

If the Northern Territory is but little known and little developed, Papua (or, to give it its old name, British New Guinea) is known still less and is even more backward in development. Official figures are not available beyond the middle of 1911, the value of the output for the pending twelve months having been about $370,000. The gold lode mining is practically confined to Woodlark island; and there is a promising copperfield at Astrolabe. Inaccessibility, climate, vegetation, and absence of means of transport, are the chief stumbling blocks in the way of progress, and development has not been carried sufficiently far to warrant a prediction as to the future of the dependency as a mineral producer.

South Australia

Of the six states of the Commonwealth, by far the most insignificant is South Australia, the value of whose last year's mineral production was about $1,940,000. Figures for even the first half of 1912 are not yet obtainable, a fact not surprising when one takes into consideration the way in which the affairs of the Mines Department of the state are conducted. What is called a 'Review of Mining Operations in the State of South Australia During the Half-Year Ended June 30, 1912,' has been issued; but all it contains in the way of statistics of production is a statement of the amount and value of the gold recovered from battery and cyanide treatment for the period. As in 1911 copper represented 86% of the total output, it would have been more to the point to give the figures relating to the production of this metal than to give plentiful details regarding the insignificant output of gold. Indeed, with the exception of a small production of iron (7% of the total) used for fluxing, South Australia's mineral output spells copper

and nothing else, and almost the whole of it comes from one mining property, the Wallaroo and Moonta. During this year rather more ore has been won from this property than was won last year, but, as stated in a recent letter, the prospects of the company are anything but favorable, as early closing of the Moonta being well within the bounds of probability, while the Wallaroo is dependent upon the continuance of the present high price for copper.

Tasmania

Last year the little island of Tasmania produced mineral wealth to the value of nearly $6,750,000, some 38% of the total coming from tin, 25% from copper, and 22% from silver and lead (jointly). The value of the production has been more than maintained this year, the value of the output for the first six months being set down officially at almost $3,600,000. The chief advance is in gold which has improved from less than 10% of the whole to nearly 13%. Tin, on the other hand, has fallen to 32%, a surprising fact in view of the present high price of the metal. The decline in tin is not merely relative, but absolute, the 3953 tons put out in 1911 giving place to 1611 in the first six months of 1912, making a drop of about 18½%. The Bischoff, which is still the chief tin mine of Australia, has almost kept up to its last year's output, and the Briseis has maintained a steady production, but the Pioneer has put out 111 tons per quarter as compared with 143 per quarter last year. The high price of tin has induced the making of a renewed effort to get the old Northeast Dundas tinfield going. There are some important tin lodes, and there may be a future for the field.

Of the Tasmanian silver-lead mines, by far the most important is that refractory property, the Hercules, which has greatly increased its output, as shown by the fact that while in 1911 it put forth 19,260 tons of a value of about $300,000, it produced in the first six months of 1912 material to the value of nearly $260,000, of which about 5% came from zincblende. The output would have been still further increased had miners been available. The 'E' orebody is opening up well; and if the present internal dissensions in the company are satisfactorily settled, the property may have an important future. Everything, however, depends upon the suitability of the process selected for the treatment of the ore, and this, as regards either of the rival schemes contending for the business of the company, may, with all due respect to those concerned, be considered problematical. The one great copper mine of the state, the Mt. Lyell, has, owing to a variety of circumstances, produced rather less blister copper than last year, but the net return has been higher as a result of better prices. Indeed when the shortage of labor is considered, the company has done remarkably well. The North Lyell branch of the property is supplying excellent ore. It is certain, as the outcome of diamond-drilling, that the orebody extends into the recently acquired property adjoining. The company now has a great work on hand in the shape of a hydro-electric installation, the fountain of light and power being found in Lake Margaret. The month of October saw a bad setback to the company, a fire breaking out in the workings, doing damage, the extent of which is hardly known as yet, and causing the loss of many lives.

Victoria

This, once the greatest of the Australian states as a mineral producer, by reason of its wealth in gold, fills now only the fourth place. Its gold yield has been on the decrease for years. In 1906 it stood at 772,290 oz. fine, last year, at 570,363 oz., this year will apparently show a still further falling off, since the yield for the first six months was only 228,135 oz. Victoria has no big mines, but it has especially deep ones. In Bendigo alone there are no less than 15 with shafts down over 3000 ft. from the surface, the deepest being the Victoria Reef, generally known locally as the 'Victoria Quartz,' which is down 4585 ft., and has a winze which descends an additional 28 or 29 ft. In the rest of the state there is but one mine, the Long Tunnel at Walhalla, with a shaft down more than 3000 ft. But it is really only in deep sinking that enterprise has been shown. As regards the importance of the fields, Bendigo is first, and the rest nowhere; and yet in Bendigo there is not a single mine fitted with up-to-date appliances. The one idea, when gold has given out, has been to sink. The ores occur as 'saddles,' occurring one below the other to unknown depths. Hence, if a reef proved poor where intersected, the rule has been to sink, and try the value of the next. But not only is there a succession of reefs one below the other, there is also a succession of parallel lines of reefs along the surface. The amazing thing is that practically only three of these many lines have been exploited to any extent, and one of these for only a short distance. Bendigonians have too readily assumed that the other lodes (contemptuously spoken of as 'side lines)' were valueless. At the present time on only one of the three main lines is mining at all flourishing, and the actual prosperity of the field is due to one of the despised 'side lines,' the Sheepshead, on which is situated the Central Red White & Blue, which last year distributed $285,000 in dividends. Its nearest rival is the South New Moon, with $70,000. The line on which this mine stands is another 'side line' though it was long supposed to be a continuation of the famous Garden Gully line. It now proves to be a line between them. Of the mines on the main lines, one paid dividends a trifle more than half of what the South New Moon distributed, and the rest were far behind it. The present time marks the triumphs of the 'side lines.' The Central New Red White & Blue has not maintained this year the fine record it put up last year, when 16,457 tons of ore treated yielded $25 per ton. The present value of the ore is less than $11, and the dividends will probably amount to less than $200,000 for the year. It will be noticed that the dividends are not expected to show the same rate of decline as the yield; that is because working costs have been reduced from about $4.50 per ton to about $3.30.

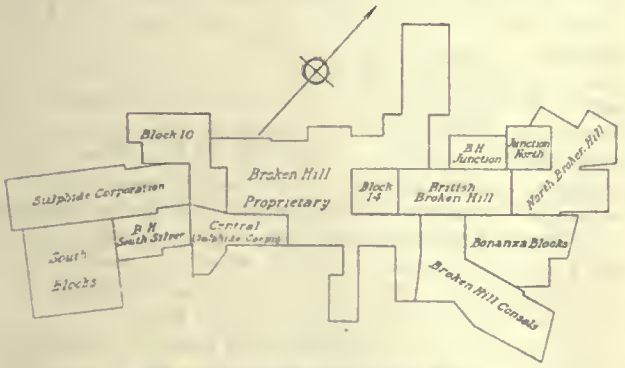
Queensland

Queensland is just about maintaining its last year's record. The gold yield has fallen, but copper and tin (which last year accounted for 32 and 8½% respectively) have both advanced, though the advance is principally on account of improved market prices rather than on account of increased output. The chief decrease in gold has been in the principal goldfield, Charters Towers, where it has been sufficiently heavy to more than counterbalance small increases elsewhere. The drop in value for the year will probably be not less than $600,000 or $700,000. In the copper fields, the Hampden and Mt. Elliott have aroused the greatest hopes, and both mines have been yielding excellent returns. Mt. Elliott is putting out about 600 tons of copper per month, and the Hampden is expected to do equally well when in full operation. That great gold and copper mine, the Mount Morgan, whose products last year were valued at about $4,250,000, is now putting out to the value of between $450,000 and $500,000 per month, so that its production for the year should show a marked advance. The gold yield has increased slightly and the copper yield enormously.

New South Wales

New South Wales, by far the greatest of all the states as a mineral producer, does not put forward any quarterly or half-yearly statements of output except as regards gold, which is far from being its most important product. In this state, as in others, the gold yield is on the down grade, the drop for the first nine months of the year amounting to 8694 oz. fine, or about $180,000. The great Newcastle and Maitland coalfields keep up their output steadily when the miners and surface hands will allow carrying on of work full time, but the companies are getting so bound down with perpetual strikes and wrangles with their employees that some are becoming disheartened. It is small wonder. The copper of the state mostly comes from Cobar, where over-capitalization is a great stumbling block. Australia's great mineral wealth is in its silver-lead-zinc mines at Broken Hill. The value of the state's output of minerals last year was, according to the *Mining Standard's* figures, between $50,000,000 and $55,000,000, and of this total, silver accounted for 15%, lead for 21%, and zinc for 13%. In other

words, practically 50% of the whole came from the Broken Hill field. Here everything has been booming, owing to the high price of silver, lead, and spelter. September was the record month, the export of the mineral products reaching a value of over $2,000,000 net. For the first nine months of the year the value, not including tin, copper, or gold, ran to over $15,000,000. The Proprietary, which is still the great mine of the field, has been working on a somewhat reduced scale, owing mainly to the difficulty of obtaining labor, and yet has, in consequence of the improved price of metals, done better than last year. The company is now planning to enter the iron and steel industry, and is thus turning into a vast industrial concern. As a mining concern, it has paid nearly $50,000,000 in dividends. In Block 14 the carbonate workings are still remarkably good. In Block 10, the lode has practically cut out at 1815 ft., and the main interest lies in the development of the 500-ft. level, which is not proving very satisfactory. The Central (Sulphide Corporation) is proving good at depth and is one of the big properties of the field. The company is going in for electric smelting, an experiment which will be closely watched. At the Zinc Corporation's South Blocks mine, re-



PROPERTY LINES AT BROKEN HILL.

cent development has added considerably to the estimated value of the reserve, but it is not yet certain that the mine has justified its purchase. At the Broken Hill South the concentrate is of lower grade than formerly, but recovery is higher, and the life of the mine has been extended by the proving of a new orebody. The Junction North has been doing much better, making a profit of from $10,000 to $15,000 per week on purchased ore and slime. The British looks remarkably well, and this year's development has added enormously to the life of the mine. No mine in the field is doing better at the present time than the North, which is working on a rich lode at the 1250-ft. level. For a mine that was supposed to be worked out years ago, it is extraordinarily lively. The mill work is excellent. The one drawback of the whole field is the insufficiency of labor. Were all the required labor obtainable, the preëminence of the district in silver, lead, and zinc production would be far more pronounced than it is, yet even as now, it is marked enough. Broken Hill is a marvelous field, and will remain such for perhaps another twenty years.

WESTERN AUSTRALIA

By Our Regular Correspondent

The year 1912 will long be remembered as one of the most stagnant in the mining industry of this state. Enterprise has been severely checked by a drought. No new finds of any importance have been made, save the finding of several nuggets, one weighing 230 oz., in two claims, two miles apart, on the Kurnalpi goldfield, caused a wild rush, which was quickly over. A smaller rush took place to Binti Binti, 50 miles northeast of Kalgoorlie, but the district is nearly deserted. In the Kalgoorlie district there have been no discoveries of any importance, but the cross-cuts, driven from the 2500, 2650, and 2800-ft. levels of the Great Boulder in the Golden Horse-Shoe ground, confirmed the diamond-drill bores of the previous year, and proved that the boundary lode had passed out of the Great Boulder into the Horse-Shoe. Practically the whole of the 2,175,000 tons, which has yielded $41,475,000, and allowed dividends amounting to $19,455,000 to be paid to Great Boulder shareholders, was mined from this lode. This means that, when the present ore reserves, last estimated at 780,000 tons, are exhausted, the Great Boulder mine will come to an end. As in the previous year the Golden Horse-Shoe has been worked at a loss, and will continue to be so worked for some months longer, till the ore from the boundary, or No. 4 lode, becomes available about the middle of next year. The ore-shoot in the Ivanhoe is short in the three bottom levels, and the grade of ore low, but there is still a four years' supply for the mill above the 2420-ft. level. Lake View & Star still has possibilities of a long life, as the Star portion of the property is almost a virgin mine, and, since Mr. Vail took charge, new finds have been made in the Lake View. The sinking of the shaft has been resumed, after remaining at 500 ft. for seven years. Associated is not looking well, but is being more systematically opened. Boulder Perseverance, South Kalgoorlie, and Hainault are treating 35,000 tons per month between them with a small margin of profit. Kalgoorlie has shown such poor results at the 185-ft. level that shaft sinking has been suspended at 1900 ft. for three years, and, during that period, the reserves have declined 180,000 tons. Oroya Links holds such a large area that it is impossible to predict its future. Golden Ridge has become so impoverished at the bottom level that the life of the mine is limited. Associated Northern is now being operated by tributors, the management concentrating its energy on the Victorious mine at Ora Banda. The treatment plant erected on the property was designated to treat 12,000 tons monthly at an estimated profit of $24,000 per month. This estimate has been completely upset by the action of the mineralized salt water on the filter cloths reducing the output of the Ridgway filters to 2500, instead of 4000 tons monthly. Chemical experiments are now being made to see if this difficulty can be overcome. This mine has 200,000 tons of oxidized ore reserves of an extractable value of $4.50 per ton. It is doubtful whether the sulphides will pay to treat, but that is a question for the future to decide. Outside of Kalgoorlie the goldfield, which shows most promise, is Meekatharra, whose leading mine, the Fenian, is now producing $36,000 per month from 3000 tons. Adjoining it on the south is the Marmont, now under option to the Great Fingall company. The Marmont yielded $675,000 from 41,500 tons, from above the 300-ft. level, and the price asked is $150,000. On the northwest of the Fenian is the Queen of the Hills owned by the Lake View & Oroya Exploration, Ltd. There are 26,000 tons of an assay value of $11.50 in this mine. A Holman pneumatic stamp-mill of a monthly capacity of 4500 tons is to be erected, and should start crushing early next year. There are half a dozen other producing mines adjoining those mentioned, but, as the district was entirely neglected by capitalists till last year, they are all worked on a small scale. In fact, till W. J. Loring, of Bewick, Moreing & Co., took an option on the Queen of the Hills, the field was entirely in the hands of working men. W. A. MacLeod, the present resident partner of Bewick, Moreing & Co., was so impressed with the district, when paying his first visit to the Queen of the Hills a couple of months ago, that he secured an option on the Marmont. The Great Fingall, at Day Dawn, which has already produced $32,920,000 from 1,780,000 tons, and paid $8,672,000 in dividends, seems to have a fresh lease of life. In 1909 the consulting engineers advised the directors to invest $375,000 of the reserve fund in the Taquah Central mine, in West Africa, as the Fingall was worked out, the lens having cut out at a depth of 1370 ft. Since then the Taquah Central has been abandoned, after the Great Fingall had added and lost another $125,000 to the original amount ventured. However, after sinking through 740 ft. of country, in the Great Fingall mine, a new orebody was found, and has been opened at three levels down to 2500 ft. The Sons of Gwalia at Lenora, which has already produced $18,200,000 from 1,832,500 tons, and paid $4,418,000 in dividends, has recently been driving on ore in No. 17 level worth $12.75

over a width of 76 in., and, in No. 18 level, ore averaging $21.50 has been found. The grade of ore recently treated by the mill has only averaged $7.50 per ton. The Yilgarn goldfield, which extends over a length of 220 miles, has shown increased activity since the flotation, in London, of the Bullfinch, two years ago, for $2,250,000. Since then the mine has been undergoing development, and a treatment plant, of a monthly capacity of 12,000 tons, is being erected, and is expected to start early in 1913. Twelve miles south of Bullfinch is the Corinthian North, one of the biggest low-grade mines in the state. The ore reserves above 100 ft. amount to 158,000 tons assaying $6 per ton. Quite recently an abundant supply of water has been met with in the shaft, which will ensure a supply for running the mill, now in course of erection. Twenty miles south of Southern Cross, and 32 miles south of the Corinthian marsh, is the Mountain Queen, controlled by Bewick, Moreing & Co. This mine has so far treated 40,100 tons with a return of $176,000 exclusive of gold in residues. A vacuum-filter is now at work, and this is expected to increase the average to $6.50 per ton. The Mountain Queen company also owns the Transvaal, situated about 12 miles away. This mine has a lode 12 ft. wide, and has ore reserves

WESTERN AUSTRALIA.

of 48,000 tons assaying $11 per ton. A treatment plant has been ordered, and should be at work early in 1913. Ten miles south of the Mountain Queen is the Victoria, on which R. Hamilton, manager of the Great Boulder, recently had nine sampiers at work for six weeks. The lode on this property is 150 ft. wide, and has a recoverable value of $6. Mr. Hamilton has now taken a twelve months' option on this property to thoroughly test it on behalf of the Great Boulder company. The price asked is $250,000 in cash, or shares, as later to be agreed on. During the year the Lancefield was shut down after producing $4,140,000 from 540,000 tons at a loss to the shareholders of $500,000. The presence of arsenical pyrite in the sulphide zone was the cause of the disaster. The mine is expected to be re-opened during the year with a new treatment plant. Another mine shut down, owing to the refractory nature of the ore, is the Gwalia Consols at Wiluna, 100 miles from the Leonora railway station. A metallurgist from Freiberg has been at the mine for a year experimenting with the ore, but has been quite unsuccessful. The Siberia Consols, situated 60 miles northeast of Kalgoorlie, may be a big producer in the near future, as the owners are at present in Adelaide with the view to an early flotation. Out of 5000 tons raised from cross-cuts and drifts on a schist ore lode 100 ft. wide, 876½ tons of picked ore yielded $103,900 at the Government mill, or the high average of $118.75 per ton. The balance of the ore raised and untreated is worth $5 to $6 per ton. Owing to the lapse of the wages agreement at Kalgoorlie, which embraces all unions in the eastern goldfields, the mining industry is abnormally depressed at present, but, once the difficulty is surmounted, prosperity should return. The gold output for the year will amount to $27,200,000 against $29,115,000 for 1911, owing to the decline in grade of the older mines, but some of the new mines should help to counteract this in the near future. Tin and copper mining have shown little increase in production, in spite of the high prices ruling for these metals, and any new finds have not so far yielded any pronounced result.

NEW ZEALAND

By F. Baxter

Although a lot of development has been accomplished during 1912 in the mines situated in the Hauraki peninsula, yet, owing to some of the principal mines in the Waihi district having been closed for several months because of labor troubles, the total output of bullion only amounted to $2,940,000 up to November, against the usual $4,000,000. Some time ago the Waihi Miners' Union withdrew from working under the provisions of the Arbitration Act, and affiliated with the Federation of Labor, which left the men free to quit work at a moment's notice. Last May the hoisting engineers at Waihi decided to form a union of their own. This was resented by the miners, and the 1200 went out on strike. Work ceased at all mines in the Waihi district until October, when operations were resumed, with other men in most cases. In November, the non-unionists were strong enough to resent being called 'scabs' by members of the 'Red Federation,' and things culminated by a striker shooting a constable, who afterward clubbed him so severely that death resulted within two days. The free workers then took matters into their own hands to a certain extent, and cleared the leading Federationists out of Waihi.

Up to the time of closing down, the Waihi mine had been yielding from $203,000 to $225,000 per month, the output to date totaling $52,400,000, out of which $22,400,000 has been distributed in dividends. The work of bringing in electric-power from the Hora Hora falls on the Waikato river, has in the meantime been pushed, and early in 1913 less labor will be required in the mine, and lower-grade ore can then be treated with a fair margin of profit. The new power-plant will cost $740,000, which sum has already been provided out of profits. The Waihi Grand Junction mine also closed in consequence of the strike. Up to April 20, 1912, this mine had yielded $3,000,000, out of which $192,000 had been paid in dividends. The work of erecting a power-station and electric pumping plant, capable of lifting 1,000,000 gal. per day, is now at hand, and unwatering of No. 3 shaft has been resumed, so that mining operations should start with the new year. The Junction mine looks well at the lower levels, and had just started paying dividends when the strike occurred. Shafts are being sunk on the line of the Waihi vein system by the Consolidated and Extended companies and the Waihi Standard Co. is also carrying on operations, having just purchased a stamp-mill, when it had to close with the other mines in the district. Owing to a deposit overlying the auriferous area in the Waihi district, the opening of mines is both slow and expensive. As the Ohinemuri river has been the sludge-channel into which the mines in that county have deposited their residue since 1895, a company has been formed, called the Waihi-Paeroa Gold Extraction Co. for the purpose of dredging the material and recovering the bullion which has been lost by the Waihi, Talisman, and Crown companies. The government returns show that over 5,000,000 tons of tailing has discharged into the river, and tests made have proved that these can be worked at a profit. The largest dredging plant in the southern hemisphere has been erected with tube-mills to treat the tailing which is finally treated by cyaniding. So far, 75,000 tons of tailing has been treated, yielding $135,000. In November, the directors declared the first dividend of 25c. per share. Full details of this plant will be given in a later issue of the *Mining and Scientific Press.*

At Karangahake, about nine miles from Waihi, three-

companies are carrying on mining operations. The Talisman Consolidated Co. has been crushing steadily through the year, and $9,200,000 has been won to date, of which $3,750,000 was paid in dividends. The New Zealand Crown Mines property, which adjoins the Talisman, has also been producing regularly, but of late returns have shown a decrease in the value of the ore treated. The total output from the Crown Mines to date is $451,000. The Dominion Company's property adjoins the Talisman, on the other side of the mountain, and an adit-level is being driven to cut lodes found on the surface. Recently a fault was cut, the rush of water from which was so strong, that work had to be stopped for some weeks. As, however, pieces of quartz which assayed over $10 per ton were found among the débris forced into the drift, it is anticipated that a lode is near. In the Komata district, the Komata Reefs Co. has been crushing steadily during the year, the total output to date being $1,950,000. Although the monthly reurns are not large from this property, they are sufficiently profitable to allow a surplus of $24,000 to have accumulated, besides covering the cost of working.

In the Maratoto district the Silverstream company is working a telluride ore, some of which has assayed as high as $260 per ton. Shipments sent to smelters in Australia have returned satisfactory averages. Tellurides of silver have also been found in an adjoining mine named the Tellurides Proprietory. In the Waioraongoami district, near the Te Aroha thermal springs sanatorium, there are a number of large lodes in the hills, but so far these have not proved amenable to treatment by the ordinary mill methods. A company called the Waitawheta has been carrying on operations for the last three years, and has found several large lodes which give good assays. It has now acquired a stamp-mill with ditch for water-power, and the directors are sanguine that it will prove a profitable proposition. Mining has been dull during the year at Coromandel, the district where gold was first discovered on the Hauraki peninsula in 1852. Work has gone on steadily at three or four mines, but nothing of importance has been reported.

The main interest at Thames centres is a cross-cut which is being driven at a depth of 1000 ft. for the purpose of testing the deeper levels. Five companies have joined in making this cross-cut, which has also been subsidized by the government to the extent of $29,000. The work has now been completed for about three parts of the proposed distance, but although one or two small veins were found and ore showing gold was opened, nothing of a sensational nature was intersected. As the cross-cut is now approaching the end of the field where the richest mines were situated in the early days, it is hoped that the downward continuation of some of the rich shoots may be found. The May Queen mine is working at 1000 ft., but so far nothing of importance has been reported, although the outlook is considered encouraging. The Saxon company has deepened its shaft 100 ft. and opened out a level which is now being driven to cut two well known veins which paid in the upper workings. The Waiotahi mine, which has yielded $3,360,000, and paid $1,920,000 on an actual capital of $74,000, is opening No. 7 level, and has intersected a lode 48 in. wide which is yielding about $20 in gold per ton. In the shaft also a large lode was found, but further sinking had to be stopped on account of the water, which, it is hoped, will be drained by the cross-cut mentioned at the 1000-ft. level. At the Tararu end of the field, three companies have done a lot of development during the past few years. The Watchman has opened up some large gold-bearing lodes, and just started a crushing of 1000 tons to prove the value by bulk test. The Waitangi Consolidated Co. mined good ore from the upper workings, but a low level put in at considerable cost, has not so far revealed profitable orebodies. The New Sylvia has opened a number of lodes, and although the ore has been low in grade, yet the last two or three shipments have shown a margin of profit. The Occidental Consolidated mine, at the other end of the Thames district, has opened an ore-shoot, and from present indications seems likely to prove profitable. It has now paid expenses for a few months and accumulated a reserve of $14,400. At Waiomo, the Monowai company has done a lot of work, and been shipping concentrate to Swansea, in England, for treatment, but there has not been anything out of operations for the shareholders so far. Kuaotuna is really part of the Coromandel field. In it three companies have been working at a profit. The New Waitala looks promising, the low level which was driven for a considerable distance has opened a good ore-shoot and the company has just completed crushing 52 tons, worth $5000, including specimen ore. The Mountain King and Handsworth mines are also mining ore, the latter company having crushed 12 tons in October which returned $2700.

Throughout the year mining shares have been neglected on the Auckland stock exchange, but apart from that fact the outlook for the goldfields is decidedly good at the present juncture, as the absence of speculative buying means that only genuine propositions are being worked.

With regard to the Reefton field, on the west coast of the South Islands, of New Zealand, an unfortunate state of affairs has also existed, due to miners in and about July last going out on strike, refusing to work 'baby' machine-drills single-handed. As a result, the well known Blackwater, Progress, Wealth of Nations, and other properties were shut down for some months. Dredging on the West Coast and in the Otago district was interesting in its usual way, but production is steadily on the down grade. On the whole, New Zealand has had a really bad year from a mining point of view, entirely through the stupidity of labor agitators; but, from the way events have turned out, they will have had a lesson which should be sufficient for many years.

After 29 weeks of idleness the Federation of Labor in New Zealand has declared the strike off at Waihi, and the Waihi and Grand Junction mines will gradually be operated to full capacity again. The men lost $675,000 in wages, against which they received a total of $125,000 in strike pay from various sources. The district's production of bullion during the strike was reduced by $2,175,000; and in the end the men gained nothing but contempt from the public generally. The strike at Reefton, in the South Island, was also declared off after 25 weeks' struggle, and the men here seem to have gained as little as those at Waihi.

Progress in Mexico in 1912

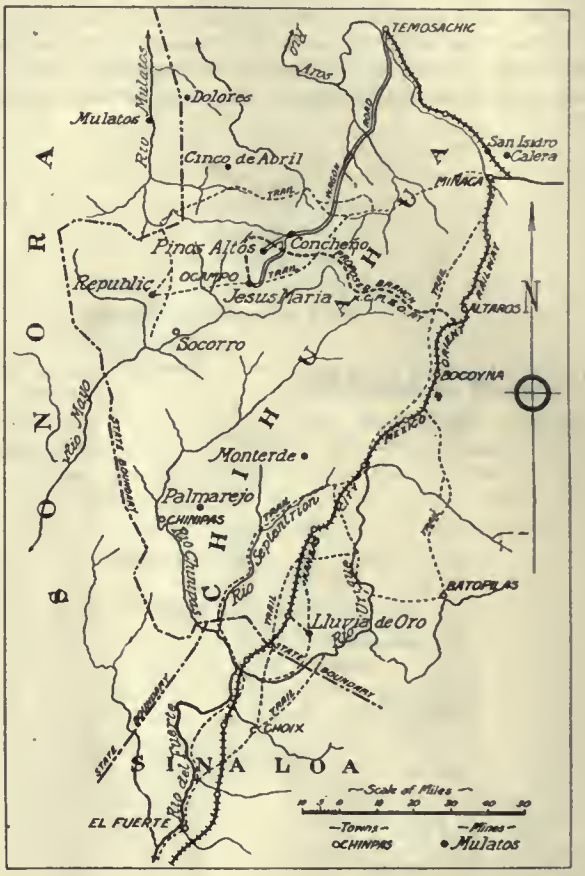
Government statistics for the fiscal year 1911-12, which includes the first six months of the present year, place the production of silver at ₱89,664,665, an increase of ₱8,750,866, compared with the production in the preceding fiscal year. The higher price was a factor in the increased production, but in addition the output was 8637 kilograms greater than in 1910-11. The gold production is placed at ₱48,686,965, a decrease of ₱928,324. In the fiscal year Mexico produced copper and copper ore worth ₱33,501,873, an increase of ₱7,201,645 over the corresponding 12 months. The increased price figured in this. Lead and lead ore produced had a value of ₱6,019,121, a decrease of over ₱800,000, and the value of the zinc ore mined and exported was ₱908,694, a slight increase. The value of the petroleum produced in 1911-12 is placed at ₱15,000,000; iron and steel, ₱7,000,000; and coal and coke, ₱9,000,000. The grand total for mineral products is ₱209,781,343.

With the favorable markets for silver and copper, normal conditions during the year would have meant heavy investment of foreign capital for new activities, and much more would have been invested for extensions and betterments. The Government was successful in putting an end to the revolutionary movement of Pasqual Orozco, launched in Chihuahua early in the year, but no crushing defeat was administered to the rebels, and in the end the forces scattered as marauding bands. Some crossed into Sonora, and by attacks on Nacozari and El Tigre came near causing international complications. Railroad lines in Chihuahua, Sonora, Durango, and Sinaloa have been cut repeatedly, and the securing of supplies has been a serious problem at many points. Mines in the states mentioned have been raided, and companies have suffered heavily. In the south the Government has had the 'Zapatistas' to contend with, and has made little progress against them. Their activities have practically put a stop to mining in important districts of the states of Mexico and Guerrero. In Oaxaca, also, mining has been interfered with extensively. In the north recently several Americans have been taken and held for ransom. During the past month there has been a decided increase in rebel activity in Chihuahua. In the taking of towns and villages in both the north and south all manner of outrages have been committed. Gen. Felix Dias, who attempted to start a revolution against the Madero government at Veracruz in October, was promptly made a prisoner.

Rebel activity has interfered with work on the Durango-Cañitas line of the National Railways, but the road has been completed for 87 kilometres out of Durango, and that stretch is now in operation. The Penjamo-Ajuno branch of the National was completed without interference. Work has been in progress during the year on the Tampico-Veracruz line of the National, which includes a connection that will give Mexico City a short route to Tampico. The Southern Pacific, which opened its West Coast line to the Tepic capital early in the year, has done no construction work.

The oil industry of Mexico has continued to develop without interruption, and the country now ranks third as an oil producer. The Doheny interests are making regular shipments to the United States under contract with the Standard Oil and associated companies, and are opening markets for oil and asphaltum in Brazil and other South American countries. The Pearson interests are exporting to England, and will soon have a new fleet of oil-carrying vessels in service. Several other concerns of the Tampico territory have reached the producing stage, and extensive exploration and development work is in progress.

In the first 10 months of 1912 Greene-Cananea had an output of 38,690,000 lb. of copper, 1,146,960 oz. of silver, and 5856 oz. of gold. The total output of copper for the year, exclusive of the product of the Miami concentrate, will not be far below 50,000,000 lb. The company has been paying a quarterly dividend of 25c. per share, placing the stock on a $1 a year dividend basis, and in addition a substantial treasury surplus is being maintained. The company's production cost during the year has been between 9 and 10c. per pound. Much important mine development and mine improvement have been in progress during the year, and the latter will result in a more economical handling of ores from the mines to the concentrators and smelter. The copper production of the Moctezuma Copper Co. (Phelps-Dodge) in the first 11 months of 1912 was 28,986,309 lb., or more than 3,000,000 lb. greater than the total production in 1911. The production in the 11 months would have passed the 30,000,000-lb. mark had it not been for the interruptions in September, due to rebel activity in the Nacozari district of Sonora, the output for that month falling to 771,884 lb. The Lucky Tiger Gold Mining Co. has been earning profits of from $45,000 to $75,000 per month, and has been paying a dividend of 5c. per share monthly,

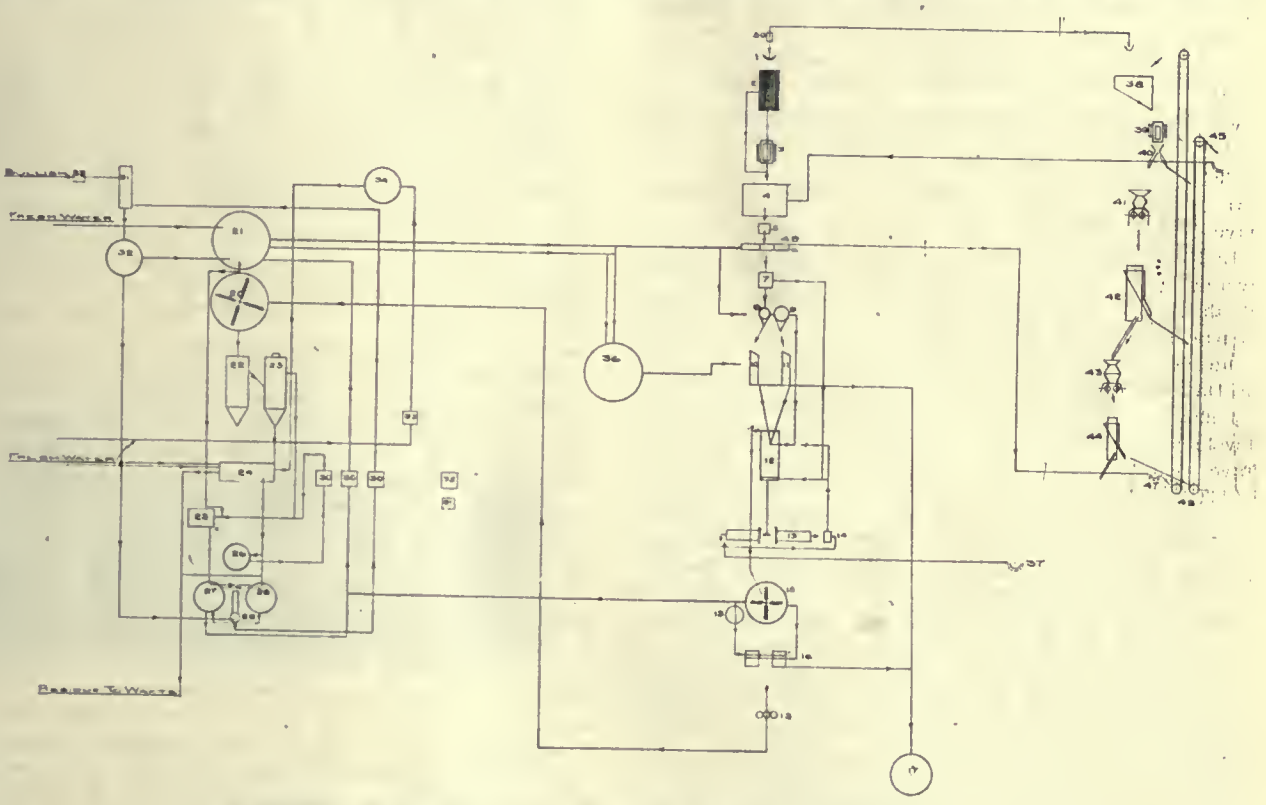


PART OF CHIHUAHUA.

amounting to $35,750. In December 2c. was added to the regular dividend, making a disbursement of $50,050. High copper prices permitted the Democrata to resume operations at its properties at Cananea. Runs have been made at the old smelting plant, and the new smelter, built before the shut-down, will be soon in operation. The Calumet & Sonora has been producing about 300 tons of zinc and copper concentrate and 50 tons of lead concentrate per month, and has been carrying on important development. Control of the Superior-Bonanza properties near Imuris was secured by the Greene-Cananea interests, and extensive work has been in progress for several months. Surveys for a railroad to Imuris have been made, in connection with plans for heavy shipments to the Cananea smelter. The San Antonio Copper Co., a Cole-Ryan concern, has continued development, and has made arrangements for the construction of a seven-mile railroad to Tonichi, the terminus of the Yaqui river branch of the Southern Pacific. The company has a great tonnage of ore blocked out, and will become an important producer. During the period of rebel activity in Sonora, operations in the Yaqui river region were affected, but shipments of ore and concentrate have been in progress for some months. The Minneapolis Copper Co. closed down at the time of rebel activity near Cumpas, but has resumed and will proceed with the erection of a smelter. The Transvaal Co. and several other concerns in the district infested for a time by rebels, have resumed. The Mexican Metals Co. has been operating

steadily, and is shipping concentrate from its 100-ton mill. The Sonora Copper Co., which has a new 100-ton smelter at copper mines near Noria station, resumed operations late in the year.

The Chihuahua smelter of the American Smelting & Refining Co. was able to continue operations through the year, treating principally ores from the Santa Eulalia district, which has continued to rank as the most important lead-silver district of the republic. Late in the year announcement was made of a deal for the transfer of the big mines of the Cia. Minera de Naica to French interests for ₱8,000,000, old stockholders assuming the responsibility of placing a part of the stock of a new company. The Mines Company of America, controlling the Dolores and El Rayo enterprises in Chihuahua and the Creston-Colorado and curtailed by traffic interruptions on the Mexican Northwestern railway, but much development has been in progress during the year. Batopilas was raided by rebels, and supplies taken, but operations were not seriously affected. The Batopilas company has been making shipments of bullion monthly. The generally unsettled conditions caused the Palmarejo & Mexican Goldfields to suspend work on its reduction plant, and the Sierra Consolidated shut down in March to await normal conditions. Rebel activity caused temporary suspensions at the Concheño and Yoquivo camps. Work on the big Conchos river power project has been in progress steadily, and every effort is being made to complete the power-plant by the middle of the coming year. Canadian interests, represented by Paul Ginther and said to be identified with those financing the power project,



FLOW-SHEET OF PROPOSED MILL, PALMAREJO & MEXICAN GOLDFIELDS, LTD.

1—Aerial tramway bucket.
2—9 grizzlies, 12 by 4 ft. by 1½-in. space.
3—Bigelow breakers.
4—Ore-bin, 1900 tons.
5—Pepler feeders.
6—Stamp battery, 36 head, 1250 lb.
7—Callow screens, 3-in. simplex.
8—3 hydraulic sizers, 3 ft. 6 in.
9—3 hydraulic sizers, 5 ft. 6 in.
10—3 Wilfley tables, coarse sand.
11—9 Wilfley tables, fine sand.
12—3 Dorr separators, double.
13—6 tube-mills, 52 in. by 16 ft.
14—3 Frenier pumps, 10 by 54 in.
15—3 Dorr thickeners, 30 by 10 ft.
16—30 Johnston slime concentrators.
17—Concentrate tanks.
18—2 wash-water tanks, 5 by 4 ft.
19—3 three-throw pumps, 9 by 12 in.
20—3 Dorr thickeners, 35 by 10 ft.
21—2 battery solution supplies, 35 ft. by 8 in.
22—6 Brown agitators, 45 by 15 ft.
23—2 Cyanippus decantors, 45 by 15 ft.
24—3 Merrill slime presses.
25—Dehne clarifier.
26—Dirty-solution sump.
27—Weak-solution sump.
28—Strong-solution sump.
29—Zinc-dust feed.
30—3 solution pumps, 7½ by 10 in.
31—3 Merrill precipitation presses.
32—Precipitated-solution tank.
33—3 sluicing-water pumps, 7½ by 10 in.
34—Sluicing-water tank.
35—Compressors for agitators.
36—Wilfley tables wash-solution tank, 20 by 5 ft.
37—Flint conveyor to tube-mills.
38—Two-compartment sample-bin.
39—Jaw-breaker, 7 by 9 in.
40—Divider, 1/6
41—Rolls, 16 by 10 in.
42—Sampler No. 1.
43—Rolls, 10 by 8 in.
44—Sampler.
45—8-in. elevator for rejects.
46—Conveyor to battery ore-bins.
47—12 conveyors from feeder sampler.
48—8-in. elevator to sample-bins.
49—Sampler at feeders.
50—Ore weighing machine.
51—Electric light dynamo.
52—3 tilting furnaces.

La Dura in Sonora, which early in the year decided to pass its dividends because of unsettled conditions and the possibility of extraordinary requirements, recently declared a dividend of 1¼% for the last quarter of the year, payable in January. A report for the first six months of the year shows bullion sales of $1,309,913, and an operating profit of $360,404. The Dolores mines was raided by rebels, resulting in a direct loss and the temporary suspension of operations. In the Parral district the Alvarado M. & M. Co. has continued uninterruptedly, and has placed additional machinery in its big cyanidation plant. The San Francisco del Oro, Minas Tecolotes y Anexas, El Rayo, and Moctezuma Lead are other important concerns of that district that have worked steadily through the year. The Veta Colorado and Arizona-Parral shut down early in the year. The Rio Tinto Copper Co. has suffered several interruptions, but has made a good showing. Shipments from mines in the Cusihuirischic district have been greatly have taken up a number of properties in the Parral district, and are reported to be planning the largest cyanide plant in Mexico. During the early part of the year the Rio Plata mill was out of commission, pending development. Since milling was resumed, it has been operating steadily. Despite difficulties, the Republica company has continued to operate profitably during the year.

The year's production of the Dos Estrellas at El Oro will average nearly a million pesos per month, and during the year the company has continued to pay dividends of ₱500,000 per month. At the beginning of the year a more favorable contract for smelting ores was made. In the year ended June 30 last, the El Oro Mining & Railway Co. had a production of £454,582, and a net profit of £182,149. The company's railway and lumber department yielded a profit of $120,220. During the year the company has been treating 20,000 tons of ore and 15,000 tons of tailing per month. Bullion worth $1,555,095 was produced from 142,884

tons milled by the Mexico Mines of El Oro in the year ended June 30. The production was maintained during the last half of 1912. The Esperanza costs have continued high during the year, with consequently small profits. At the company's annual meeting in May, it was shown that £40,000 had been taken from the reserve fund to pay dividends of £138,000 during the preceding year, and it was decided to readjust disbursements. Negotiations for a property in Zacatecas have been in progress during the year. The 1912 net earnings of the Real del Monte y Pachuca, in the Pachuca district of Hidalgo, will be double those of the preceding year. In addition, ₱1,000,000 of deferred charges from the cost of doubling capacities two years ago have been charged off. The company commenced the year milling 32,000 tons per month, and in November last the amount milled was 39,200 tons. The December record is expected to show 41,000 tons milled. The gross earnings of the Santa Gertrudis, Ltd., for the year ended in June were £631,432, and the net earnings £276,648. The dividend disbursement amounted to £205,200. The capacity of the Santa Gertrudis plant has been increased from 650 to 850 tons per day, the work being completed late in the year. The San Rafael y Anexas and La Blanca, at Pachuca, have had a successful year.

In the state of Jalisco the Amparo Mining Co. has been averaging ₱140,000 per month, with operating expenses of about half that amount. The company has continued to pay dividends of $60,000 quarterly. El Favor has been a heavy shipper of high-grade ore during the year, and in December the company declared its first dividend, 1c. per share. Mololoa has been shipping high-grade ore from development and has been milling extensively at the El Favor plant. An option to buy the Casados mines for ₱4,500,000, held by American and French interests, was surrendered late in the year because of generally unsettled conditions. During the year important and satisfactory development has been conducted. Extensive work has been in progress for several months at the old Cinco Minas, and orders have been placed for a 250-ton cyanide plant. During the year the Espada Mines Co. has been milling at the Virginia & Mexico plant, and some time ago reached a capacity of 100 tons per day. Late in the year arrangements were made for the construction of a branch of the National Railways from Ameca to the Magistral copper camp, and the coming year should see great activity in the Ameca district. El Tajo, in the San Sebastian district, has been working steadily. The Mexicana bought a 50-ton copper smelter for its mines in the Tapalpa district, but because of general conditions little work has been done during the year. The Mexican Mines Co. recently resumed at the old Bolaños mines, having stopped work early in the year. The Guanajuato district of Guanajuato continued to produce over ₱1,000,000 per month during 1912 and the enterprises there have suffered no direct interference. Recently financial reasons caused the Oro Grande practically to abandon work at the old La Luz and the Jesus Maria properties. American capital has been secured for extensive operations at the San Gregorio and Dolores properties of the Dwight-Furness interests. In October the Cia. Beneficiadora de Pozos completed a 250-ton cyanide plant, which will treat the ores of the Angustias, Dolores y Anexas, and other mines of the Pozos district of Guanajuata. The year's operations of the La Fe y Anexas Co., controlled by the A. Goerz interests of London and operating in the Zacatecas district of Zacatecas, have been very extensive. The company has put in additional pumping equipment to handle the water in the old mines and has ordered a 30-stamp concentrating and cyaniding plant. The important Mazapil Copper Co. has operated its mines and smelters uninterruptedly. The 100-ton plant of the Santa Rosa Mining Co., in the Concepcion del Oro district, started near the end of 1911, has been in successful operation the past year, and good profits have been earned. The mines and 50-stamp mill of the San Carlos Gold Mines, Ltd., of London, at Mezquital del Oro, Zacatecas, were taken over by Philadelphia interests, and the Mezquital Mining Co. formed.

The Velardeña smelter of the American Smelters Securities Co., in Durango, has been able to continue operation practically throughout the year, notwithstaning the fact that for months there was much rebel activity in that part of Durango. To maintain a fuel supply has been difficult. For some time the smelter has been averaging 1600 tons of ore per day, the greater part from the company's Velardeña mines. The production of all the mines in the Velardeña district has been almost normal. A new sintering plant is being built at the smelter, and when completed it is expected to handle a big tonnage of fine. The Peñoles Mining Co., owning the smelter and the principal mines at Mapimi, has been operating steadily. The company bought the Paloma lead-silver mines in Coahuila for ₱1,000,000, and has been negotiating for the Cabrilla mines in the same camp at a price said to be double that of the Paloma. A decision to use oil for fuel was reached during the year by the Peñoles management, and a contract made with the Doheny interests. Rebel activity checked operations in the Inde district of Durango, but the Guadalupe and the Inde Gold, the two most important concerns of the district, have resumed work. The Tominil company, an English concern operating near the Sinaloa line, was forced to abandon operations several months ago. Apparently disturbed conditions have served only to delay the plans of the promoters of the Nazas Valley & Pacific railway, projected from Tepehuanes to Guanacevi, Durango, as it is announced that grading will be commenced immediately. The Torreon smelter has been in operation throughout the year, but at reduced capacity during much of the time. The smelters at Monterey, Aguascalientes, San Luis Potosi, and Matehuala also have been operating uninterruptedly. The Central Potosi railway, giving the Tiro General mines, in San Luis Potosi, connection with the National Railways, was widened to standard gauge during the year, making possible heavier shipments to the Aguascalientes smelter. The Tiro General mines were bought by the American Smelting & Refining Co. in 1911. El Barreno started its new reduction plant in the San Pedro district of San Luis Potosi early in the year, but later some remodeling was found necessary. The Wadley antimony smelter of Cookson & Co. has had a successful year. German interests having under lease the Cerritos sulphur deposits of the Virginia-Carolina Chemical Co. have been producing heavily during the year. The Teziutlan Copper Co., of Puebla, has been producing heavily at its mines and smelter. An order for four 8-ft. Hardinge mills was recently placed. The Puebla Smelting & Refining Co. has been organized by American interests, with a capital of $5,000,000, to work a group of copper mines in the San Juan district of Puebla. The plants include a 1000-ton smelter. The Mexican Light & Power Co., the Canadian concern owning the big Necaxa plant in Puebla and supplying power to the El Oro and Pachuca districts as well as to Mexico City, had gross earnings in the first 11 months of the year of ₱8,109,306 and net earnings of ₱5,862,157. The increase in net earnings over the same period of 1911 was ₱833,995. The holdings of C. A. Hamilton in the San Juan Mining Co., owning the rich San Juan mine in the Taviche district of Oaxaca, were sold to L. R. Wiifley for ₱1,000,000, but recently a legal controversy has arisen over alleged nonconformity with the terms of payment. The San Juan has continued a heavy shipper of rich ore. Machinery for a complete 150-ton cyanide plant was bought by the Cubilete y Anexas Co. for its mines in Oaxaca.

The old Huicicila mines in Tepic were taken over by W. R. Ramsdell and associates, and the Miravalles Mining Co. organized. The reopening of the old mines is in progress. The Mexican Searchers, Ltd., has been steadily at work at the old San Jose de Ventanas mines in the Pinavete camp of Tepic, which are under option, and the purchase probably will be made soon. The Minas del Tajo, the Los Angeles concern operating the Tajo properties in the Rosario district of Sinaloa, has leased the adjoining Guadalupano mine and is working it. The Boleo Copper Co., of Lower California, has averaged over 2,000,000 lb. of copper monthly during the past year, and the total will not be much below 30,000,000 pounds.

Special Correspondence

BUTTE, MONTANA

WORK OF THE ANACONDA COMPANY.—PHOSPHATE DEPOSITS.—RADERSBURG NEWS.

The Pilot-Butte Mining Co. has found several feet of good copper ore in its shaft a few feet below the 1600-ft. level. The shaft is to be continued to the 1900-ft. level before any extensive lateral development is attempted. The ore was found in a northwest fault vein north of the Badger State mine, and angurs well for an extension of the copper zone into this territory. It is rumored that the Tuolumne Copper Co. will pay a dividend in January. The cross-cut on the 2000-ft. level has still about 200 ft. to go before reaching the vein, but earnings from recent ore shipments have been gradually increasing, and the company's treasury now contains about $200,000. The Krao Silver-Lead Mining Co., with property near Ainsworth, British Columbia, but largely owned by Butte stockholders, is considering reorganization. Henry J. Pierce, of Spokane, proposes to organize the Krao Mines, Ltd., and exchange old stock for new on an option basis extending for a year.

The State Mine Inspector's report for 1912 summarizes the operation of the Anaconda Copper Mining Co. as follows: Miners employed, 7339; surface men, 1699; miscellaneous employees, 3175; total 12,314. The mines operated during 1912 were the Anaconda, Mountain Consolidated, J. 1. C., Original, Pauline, Gagnon, Silver Bow, Tramway, Leonard, Badger State, Never Sweat, Belmont, Stewart, Parrot, West Gray Rock, Berkeley, Mountain View, West Colusa, Diamond, St. Lawrence, High Ore, Right Bower, Moonlight, Little Mina, Pennsylvania, and East Colusa. The following men are named as the operating force: C. F. Kelley, general manager; John Gillie, general superintendent; C. W. Goodale, B. H. Dunshee, and J. C. Adams, superintendents.

PART OF BUTTE.

Recent announcements show that the U. S. Geological Survey has been actively investigating the rock phosphate possibilities in Montana. The Government geologists claim to have made important finds in the following four places: (1) Beaverhead county, near Melrose; (2) Powell county, near Garrison; (3) Powell county, near Elliston; (4) Jefferson county, near Cardwell. The completion of the railroad from Anaconda is reviving Georgetown and its vicinity. The Southern Cross mine, owned by the Anaconda company, is erecting new surface buildings and preparing for the installation of a new compressor. Considerable building and other improvements are under way in Georgetown.

The Souvenir Gold Mining Co., in Lewis and Clark county, with property adjacent to the Whitlatch-Union at Unionville, is considering the sale of its property to Eastern capitalists. The North Star Mining Co. expects to erect a 50-ton concentrator on its property near Stemple. A 4-ft. vein of workable silver-copper ore has recently been developed.

The Ohio-Keating Gold Mining Co. has recently made a promising find on the 300-ft. level north in its Ohio mine at Radersburg. Details of the find have not been given out. Owners of the Robert E. Lee mine, at Radersburg, have brought suit against the Black Friday Gold Mining Co. to recover the value of ore claimed to have been unlawfully extracted from their property by the Black Friday company. The Rena mine is closed down, having been unable to handle a big flow of water developed in one of the drifts. The Butte & Radersburg Mining Co. is planning to resume operations. It is claimed that financial arrangements have been made for the completion of the railroad from Three Forks to Radersburg.

The Barnes-King cyanide mill at Kendall started on December 14, treating 100 tons of ore per day from the newly acquired Santiago orebody. The ore assays about $8 in gold per ton. The mill will run full capacity, 200 tons per day, as soon as the mine stopes have been opened up sufficiently to deliver that amount.

NEW YORK

COPPER OUTLOOK.—MARKET NOTES.—NEW ENTERPRISES.—ADMEEK AND MOHAWK.

The copper outlook for the coming year is the principal centre of interest in mining matters in the East. The deadlock which has existed between the copper producers and the manufacturers has shown some signs of giving way before the necessity of current business, and some very satisfactory and substantial orders for copper have been booked. The principal feature during 1912 was the possible amount of new copper which would have to be taken care of. A year ago estimates as to this item ranged around 200,000,000 lb., and, while the development in this direction has not been quite so rapid as was anticipated, all things considered this figure was not very far out of the way. December figures are not yet available, but the product can be reckoned within a small percentage, so that it is safe to say that the total output for the year will figure very close to 1,600,000,000 lb., an increase of nearly 145,000,000 lb. over 1911. Not all of this added output is by any means due to new properties. The Anaconda produced more than 30,000,000 lb. in excess of 1911 production; the Phelps-Dodge company averaged approximately 1,000,000 lb. per month above the figures of a year ago. Utah Copper and Nevada Consolidated can hardly be fairly compared with last year owing to labor disturbances, and similar comparisons would be out of place for the Granby and the British Columbia as these properties suffered enforced shut-downs.

As regards the copper surplus it stands somewhat above what it did one year ago, the increase being about 15,000,000 lb. as compared with the surplus at the close of 1911. Next year will see new copper possibly more of a problem than it was in 1912, some of the mines that were expected to become factors in production during the past 12 months having developed somewhat more slowly than was expected, but such developments have been wholly favorable and in order to maintain the balance between production and consumption there will have to be a reasonable increase in the latter if accumulation of surplus stock is to be avoided. This is especially true in view of the fact that there still remains as a hidden factor in the situation such copper as may be held up in the refinery yards.

The dividend resumptions and increases have come a little more slowly than might have been expected. Tennessee Copper Co. has declared a dividend of $1.50 per share, an increase of 50c. over the last disbursement, paid in August 1912. The Mohawk Mining Co. made a similar increase in its dividend and will pay $3 per share February 1, against $2.50 paid in mid-summer of last year. The Tuolumne Mining Co. has declared a dividend of 10c. per share as a quarterly payment, the first dividend which has been paid for a year or more, when 15c. per share was paid quarterly. The possibility of a resumption of dividends by the Granby is being used as market ammunition, and there is evidently some pressure on the part of some of the stockholders, who insist that it is unfair to ask that the holders forego all income while earnings are diverted to the equipment of the Hidden Creek property. The stub-

born attitude of the public in regard to the entire copper situation has been many times a matter of comment. In this regard it is interesting to note that 20 leading copper stocks have been shown during the recent slump a decline of 18.6% as compared with a drop of 7% for 20 active railroad stocks, and a drop of 9% for 12 active industrial issues. This attitude is somewhat more remarkable considering the progress made by Utah Copper, which in 1912 reached the 100,000,000 lb. mark and produced its copper at approximately 7.5c. per pound.

The United States Steel Corporation on December 30, 1912, bought 7,000,000 lb. of electrolytic copper for the bulk of which the producers' full price of 17.75c. for 30 days, delivered, was paid, although outside lots helping to make the total amount, were picked up at 17.62½c., 30 days, delivered. December deliveries of tin into U. S. consumption were large, amounting to 4050 tons, which exceeded all estimates. Total deliveries for 1912 were 49,500 tons, or 5200 tons over those of 1911. The total visible supply of tin (Europe and United States), December 31, 1912, was 10,977 tons, or 5537 tons less than the total visible December 31, 1911.

The Penn-Wyoming Copper Co. is about to go through another one of its periodical revolutions, the Federal court having just handed down a decree of foreclosure for the sum of $2,500,000, under deeds of trust given to the Continental & Commercial Trust & Savings Bank of Chicago. The various organizations and re-organizations of the Penn-Wyoming Copper Co. and its various subsidiaries, mergers, and absorptions form one of the undesirable chapters in the history of mining finance in America.

There are a few new enterprises being launched. The Bessie Gold Dredging Co. has been admitted to quotation privileges on the New York Curb. The Chile Copper Co. has been organized under the laws of the state of Maine with a capital of $20,000,000. Probably of more importance is a despatch to the effect that an Anglo-American Russian syndicate is about to undertake the development of a big placer gold property on the Patoum river in Siberia. The syndicate is said to be acting under the advice of John Hays Hammond, while an American engineer, W. E. Thorn, is to be in charge of operations. Despatches from Arizona to some of the larger shareholders in the East state that the drills on the South Live Oak property near Miami have cut a most encouraging body of porphyry ore, and the management is hoping to develop another big low-grade milling copper mine. The Tuolumne shareholders throughout the East are largely interested in Pilot Butte, the neighboring property to the Tuolumne, which is being developed under the same management, and are very much interested in the news of a recent find in the Pilot Butte of some 4 ft. of ore, carrying good copper and silver content. It is believed that the vein is the Berlin, from which vein the North Butte has taken some of its richest ore. No attempt is to be made at this time as to production, but the Pilot Butte shaft will be sunk some 300 ft. farther and another cross-cut driven to open a vein on that level.

The Boston market was somewhat exercised during holiday week by rumors of a consolidation of the Ahmeek and Mohawk. The Ahmeek has been very much in the limelight since its bitter fight against the Calumet & Hecla consolidation. The property is managed by Calumet & Hecla interests, but the big company does not hold control. The Mohawk is one of the Smith-Stanton properties and has just completed its most successful year. It is quite safe to say that the Ahmeek people who refused to be absorbed into the Calumet & Hecla would be equally strenuous in their opposition to a merger with the Mohawk, and it would undoubtedly be quite impossible to arrive at appraisals satisfactory to both companies so that a basis of exchange could be formed. Ahmeek is selling for approximately $330 per share, and as this figure makes the issue somewhat unwieldy for market purposes, it is intended to increase the capital stock from 50,000 to 100,000 shares. The Houghton Copper Co., which lies between the Isle Royale and the Section 16 mine of the Atlantic has been recently making some developments that border on the sensational. The Houghton is controlled by the St. Mary's Mineral Land Co., and on its present showing may be counted as one of the coming important producers of the Lake country.

The attitude of the Western mining man toward the somewhat aggravating condition of affairs in Mexico is shown by a letter just at hand from one of the leading figures in Colorado mining circles, who has representatives in nearly all of the important districts in Mexico. He writes: "As far as the Mexican situation is concerned, I am under the impression that the situation is about as bad as ever it was. If we had an aggressive President in the executive chair of this great United States, I think 10,000 cowboys with a first-class general in charge could sweep the whole country from Cape California to Vera Cruz."

BOSTON

CALUMET & HECLA IMPROVEMENTS.—EAST BUTTE.—SMELTER FUME LEGISLATION.—LAWSON'S ACTIVITIES.

Mild weather so far this winter in the Lake Superior region has been very welcome to the copper mining operators, as it has helped out where work has been hindered by labor shortage. Nearly all the mines have taken advantage of the mild weather to push operations, especially the Calumet & Hecla which has made additions to its surface equipment, enlarged the power plant, and built a re-grinding plant and electrolytic works. It is estimated that the re-grinding plant will treat tailing at a cost of about 6c. per pound of copper, including freight and expense of marketing. This will develop a big reserve for Calumet & Hecla and will greatly prolong the life of the property.

East Butte has been holding steady in the market, which is taken as the best evidence that it has its finances well in hand. On the first of the year the company retired $100,000 of the $500,000 notes which were issued a month earlier to meet the full payment for the Pittsmont property. The remaining four notes of $100,000 each mature February 1, March 1, April 1, and May 1 of this year. The company is at present earning over $125,000 per month, the earnings coming from the production from the Pittsmont mines and the revenue from custom smelting. The company has all the materials ready to increase the size of the two furnaces in its smelter 75%, which will give that plant a capacity of turning out around 20,000,000 lb. of copper annually. Making these additions will enforce the closing down of the furnace for 30 to 60 days, but the other furnace will continue work while reconstruction is in progress. The work will be completed during the spring and East Butte will have the advantage of increased capacity during the closing months of 1913.

Boston is greatly interested in the work which the Los Angeles Chamber of Mines and Oil has volunteered to assume in asking legislation looking to the settlement of the smelter fume troubles in the Shasta county, California district. The two Lawson companies, First National and Trinity, are most directly affected by the decree which forbids the operation of a smelter in that section. The Mammoth smelter of the United States Smelting, Refining & Mining Co. has also been affected in being required at heavy outlay to construct a bag-house which, while it has successfully met the difficulties, has materially cut down capacity. As these companies are native to Boston, the initiative of the Los Angeles body is being watched with great interest. Inasmuch as small fruit farm interests for as much as 30 to 40 miles around have been able to keep the First National mines and smelter, working 500 men and producing millions of value annually, closed down, it seems that some solution should be reached and an end placed to a vexatious situation.

T. W. Lawson in *Everybody's Magazine* explains his advertised stock operations, taking up Nevada-Utah first, calling it a closed book and disclaiming responsibility for it. Yet "Buy Nevada Now" headlines were prominent in Boston newspapers five years ago. He claims, of course, full credit for pointing the public to Chino, with its $40,000,000 of profit. But the point should be made also that had Chino (or Santa Rita) remained in the hands of Lawson and his crowd it would undoubtedly have been a much

longer time getting to production, if it ever reached it. Lawson's development and management of copper properties has been disappointing, though he has picked some winners, such as Chino.

TORONTO, CANADA

PROGRESS OF THE PORCUPINE STRIKE.—NEW MILLS.—LIFE EXTENSION OF THE COBALT DISTRICT.

Anticipations of a speedy termination of the Porcupine strike by an influx of strike-breakers from outside have been verified, and it is now apparent that the earlier reports to the effect that the backbone of the strike had been broken, and that the leading mines had all the labor they required, were altogether too optimistic. It is true that large numbers of men have been brought in, but the statement of the Western Federation of Miners that these are nearly all inexperienced men who, for some time at least, will be of little use in the mines appears to be substantially correct. The Dome management maintains its habitual policy of silence, beyond intimating that the full quota of men is now at work, but there is a significant absence of any official or other statements as to output. The monthly statement of the Hollinger frankly admits the difficulties under which operations are conducted owing to the lack of skilled labor. While the mill has been kept running, and is prepared at any time to resume crushing to its full capacity, the production has been limited to an amount sufficient to provide for the payment of dividends. The output for November was curtailed by nearly one-half, that month showing a profit from milling of $94,613. The provisional balance-sheet submitted showed a surplus on December 1 of $763,385, out of which the second dividend was payable. Allowing $83,000 for reinvestment in plant, the available balance in reserve for dividends was $339,752. The financial position at the end of the year is estimated at about the same. Allowing a somewhat smaller output for December than that of November, estimated at $125,000, the total gold production to date is in the neighborhood of $825,000.

The Pearl Lake shaft has nearly reached the 600-ft. level, at which a cross-cut will be driven to cut the rich vein found at the 400-ft. level. An order has been placed for a 30-stamp mill which it is hoped to have in operation early in the spring. The Rea mine has been leased to John Redington for five years, with option of renewal, for a payment of $6000 cash and 25% of the profits. Mr. Redington agrees to erect a 25-ton mill, which is to become the property of the company when the lease expires. A new company, to be known as the Mines Leasing & Development Co., is being organized to operate the mine, capitalized at $200,000. The 10-ton mill at the Hughes has been running on high-grade ore since the middle of December. The ore broken from the 156-ft. level, where the vein is 8 ft. wide, is reported to average $150 per ton. A large body of ore is being blocked out in preparation for the installation of a big mill next summer. Twenty tons of ore from the Tough property, in the Kirkland Lake district, stated to be very high grade, has been shipped for smelting. A previous consignment of two tons averaged $369 per ton.

The discoveries of the last few months pointing to the extension of the life of the Cobalt district with deep mining, and the announcement of some big dividends in January, have maintained an active market for Cobalt shares even during the usually dull holiday season. The Buffalo has declared its regular 5% dividend and 18% extra, and the McKinley-Darragh gives a bonus of 17% with its usual 3% dividend. The financial statement of the Beaver shows an available balance of $141,873 on December 1. The company is working in 2700-oz. ore on the 600-ft. level, and has cut a station and started cross-cutting at the 700-ft. level, where a strong vein 2 in. wide has been found. An addition which will increase the daily capacity of the mill to 100 tons will shortly be in operation. The Conlagas showed net profits for the year ended October 31 of $1,701,553, and had a balance on hand of $1,278,988. The silver shipments were 3,508,377 oz., which was mined and concentrated at 8.51c. per ounce. The ore reserves were conservatively estimated at 13,953,000 oz. The position of La Rose has been improved by development work during the year. Cross-cutting is being done to reach a vein yielding 2000-oz. ore, which comes into the property from the Right of Way at the 62-ft. level. No. 4 vein on the adit-level is showing ore on the face of the drift, and a promising new vein has been found on the north side of the Lawson shaft. Net profits for the year ended December 31 are estimated at approximately $1,000,000.

JOPLIN, MISSOURI

OPEN-PIT MINING.—PROTECTING MINES FROM FLOOD-WATERS.

Open-cut work is growing more common in the Joplin district, the high prices that have prevailed for zinc ores having made it possible to handle much leaner dirt than could be handled at a profit in former years. Improved milling conditions, thus making possible a better recovery of the contained mineral, likewise play a part in enabling operators to develop properties that had either been worked extensively and abandoned, or to go into virgin regions where the ore is thin. In the former case much open-cut mining has resulted, a common practice being to equip a property with large milling capacity and to handle an enormous tonnage of ore. It has been found possible to so treat, at a profit, ores carrying less than 1½% blende. A number of large open-cut mines are now being operated, one of the latest being that of the Minor-Heir Vantage Co., operated by the Sheridan-Adams Royalty Syndicate, in the sheet-ore district north of Webb City, Missouri. The ground was worked originally by gougers who sought only the shallow lead found a few feet beneath the surface. Development was carried to greater depths later, and eventually, as the result of high driving, the ground caved in, leaving a big open pit, more than 100 ft. in diameter and 130 ft. deep. In the sheer sides of this pit are exposed the door-like openings of the shallow drifts, near the surface, barely large enough to accommodate the body of a large man, while the high arched openings of the larger drifts are seen toward the bottom of the cave. At one time Center creek, which now flows several hundred yards to the north, passed over this land, leaving a stratum of gravel in which free galena is found. On top of the gravel is a layer of 'made' ground, representing the accumulation from an old concentrating plant formerly operating on the lease. The Minor-Heir company has increased the capacity of the mill, run an inclined tramway into the pit, purchased a steam-shovel, and is now caving all the dirt from the surface to the bottom of the pit, the entire volume thus procured being milled.

A concrete collar, constructed around the opening of the shaft of the Yellow Jacket mine, northwest of Joplin, and extending 6 ft. above the ground, protects the mine workings from flood-waters from Spring river and Center creek, two streams which flow nearby and which frequently overflow their banks. The mine, operated by O. W. Sparks, of Galena, Kansas, is situated in the low flat river bottoms, and as a rule this part of the country is inundated in the spring of the year. Mines in the one-time rich Badger-Peacock district, a short distance to the north, formerly suffered greatly from the flood-waters. The new district which is just being opened is similarly situated, and Mr. Sparks has taken this method of protecting his property. Development at the Yellow Jacket mine, which showed an extensive body of high-grade zinc, caused an extension of the zone of prospecting to the south, and as a result new discoveries were made which resulted in the building of a second and larger mill by the same company, the new plant being known as the Yellow Pup, while across Spring river, to the west, the Lynas Mining Co. is constructing a large concentrating plant. The ore occurs in large bodies in all the mines mentioned, while the concentrate averages higher than 60% zinc. Picking out waste rock from the ore after having passed through the grizzly and before going to the shaking screen has been practised at the Schoenherr-Walton mine, north of Webb City, and gives an increased milling capacity.

General Mining News

ALASKA

Cordova

A proposal was recently submitted to the Cordova Chamber of Commerce in which a company offered to erect a 50-ton daily capacity oil-blast copper smelter in the town, provided the local business men furnish 10 acres of land on the waterfront with good dock facilities, not too far from the railroad, supply the buildings for the plant, to cost $15,000, and furnish up to $50,000 cash. The stock of the Copper Reduction Co., capital $200,000, was to be given at par for the full amount of cash provided and the cost of the buildings erected. Cordova decided that some other town should be permitted to supply the above necessaries.

Fairbanks

On December 9, J. Letterman sold to Ronan & Cunningham a half interest in what is known as the Spalding property, on Lane creek, for $30,000. This also included the 3-stamp mill which was destroyed on the previous day, and other small interests.

Juneau

During November the Ready Bullion and 700-Ft. Claim mills crushed 36,773 tons of ore, yielding $45,629 by amalgamation, and $44,478 from cyanide treatment of 983 tons of concentrate. The estimated net profit was $40,752. Development covered 349 and 109 ft., and the stock of broken ore decreased 1880 and increased 4239 tons, respectively. The Alaska Mexican 120-stamp mill crushed 18,564 tons, yielding $17,801 from free gold and $19,944 from 401 tons of concentrate. The net profit is estimated as $11,922. Development covered 327 ft., and the stock of broken ore increased 2327 tons.

ARIZONA

All producing mining companies in Arizona have been notified by the State Tax Commission to present reports showing their net and gross production for 1912. The figures are to be submitted as soon after the first of the year as possible. No details are required. The Commissioners merely want to know what each mine produced and what that production netted after the costs of mining, transportation, and treatment had been paid.

Gila County

From the Inspiration mine about 20,000 tons of ore per month is being saved during development and is put on the stock pile until the mill is ready. Good progress is being made with the construction of the Arizona & Eastern railroad from the Miami to the Live Oak terminal. The Inspiration Consolidated has made a contract with the Reclamation Service for surplus power at the Roosevelt dam which assures the company the cheapest power of any mine in the Southwest. At the site for the concentrating plant, a steam-shovel is now working, and 250,000 cu. yd. of ground will have to be moved.

Mohave County

(Special Correspondence.)—The United States Smelting, Rfg. & Min. Co., owner of the Gold Road mine, will be the first corporation in northern Arizona to obey the new semi-monthly pay-day law, which goes into effect at the Gold Road property in January. This mine employs 200 men and is producing from $70,000 to $80,000 per month. The Gold Road has a body of pay-ore 3000 ft. long, and ore is still being mined in the 700-ft. level, driving east. The output of the Tom Reed for December is estimated at $125,000, the dividend disbursement for the month being 7%, or about $65,000. The largest production for any one month was October, when the total was $132,145. With a production for 1912 of nearly $1,100,000, the Tom Reed at the present time is the premier gold property of Arizona. The reported find in the Olla Oatman west 450-ft. drift, at a distance of 400 ft. from the shaft, is confirmed in so far as having a large body of low-grade ore, not, however, up to the standard value of the average ore of the mine. Additional depth is needed on this new orebody, which may eventually be larger than the three ore-shoots now being mined.

The Vivian Mining Co., and the Boundary Cone M. & M. Co., operating extensively in the Tom Reed area, have ore in and below the older andesite contrary to the opinions of probabilities given by F. C. Schrader in his report of the U. S. Geological survey, Bulletin 340-A. The Vivian company, owner of the Leland-Mitchell, has sunk to a depth of 390 ft., the vein being a contact between the newer and older andesites. A new plant has been erected and two Fairbanks-Morse 40-hp. oil-burning engines placed in commission. Sinking will be resumed about January 1 to 600-ft. depth. Harold Banning, of Los Angeles, Mr. Ross, and other capitalists of southern California are backing the new development. The Boundary Cone company passed into the older andesite at 200 ft. At 450 ft. the richest ore in the camp was found in a 14-ft. winze, after driving a short distance east of the shaft. The bottom of the winze shows a 2-ft. vein returning 12.75 oz. gold, and the average of 6 ft. is $67.90. This company is down 510 ft., and at 550 ft. will cross-cut to the vein. The principal owners of this property are prominent mining men of Los Angeles and vicinity, and their work justifies the opinion of W. H. Weed, in his article of June 1910, upon the Tom Reed district, that pay-ore in the lower and older andesites is not only possible, but certain with properly planned development. Many new properties are being started, and the year 1912 has been the most prosperous period of the goldfields of Mohave county.

Oatman, December 26.

Pinal County

In the Superior district of this county the Magma Copper Co. is shipping 100 tons of high-grade copper ore per week to the El Paso smelter. The ore is a chalcocite and bornite, containing gold and silver. Fifty men are employed, and the power-plant is finished. This property was originally called the Silver Queen, being first opened in 1874. The Gunn-Thompson company secured control about two years ago and has been successful in opening rich ore on the 650 and 800-ft. levels. The Calumet & Arizona, situated 3½ miles southeast from Superior, has 80 men at work. A 3-compartment shaft is down to 75-ft. depth, and a good head-frame is being erected. The Guggenheim Exploration Co. has a few men at the Black Diamond mine. The ore occurrs in heavily mineralized iron-manganese gossan.

Santa Cruz County

It is stated that a good offer has been made for the Ramsdale properties, situated between Harshaw and Duquesne. They contain large quantities of low-grade copper ore. T. B. Anderson, of Tucson, representing the United States Smelting, Refining & Mining Co., is visiting Patagonia and examining mining properties. This company held an option on the R. R. R. mine, but allowed it to lapse.

Yavapai County

The property of the Harris Copper Co., on the Agua Fria river, 50 miles north of Phoenix, in the Tip Top mining district, consists of 550 acres and a water-right. About 800 ft. of development has been done, and in the Casadilla claim 1000 tons of copper ore, worth $15 per ton, has been opened. Hand drills have been used so far, but it is intended to sink a shaft, cross-cut, and erect machinery to cost $11,000.

The syndicate which recently acquired the United Verde Extension mine has also taken a bond on the Jerome Verde, and the two options will run together, on the same conditions. If these properties prove worth buying, this syndicate will go in for extensive development and plant. A large vein carrying copper and gold has been opened on the Ratcliff claims. The Puntenney lime quarries are employing 100 men and producing a high-grade lime from the kilns. From the old United States mine in Copper

basin a carload of lead-zinc ore is being shipped. The Senator adit is about 3200 ft. long, and at 3000 ft. in, a drift is being driven on the Cashier vein.

CALIFORNIA

Amador County

It was recently decided by those owning a majority of the stock of the Lincoln Consolidated company to close it down, notwithstanding that the minority holders were willing to go ahead with prospecting. The trouble is in connection with assessments on stock and that certain holders had reserved non-assessable stock. All kinds of rumors are afloat regarding the company, which is headed by W. J. McGee, and nothing is definite as to future plans, although it is stated that the owners have tried to sell the property for some time past. The *Amador Record* of January 2 gives details of the present state of the property.

Calaveras County

It is stated that the smelter at the Calaveras property, at Copperopolis, was to have been blown in early in January. Over 400,000 gal. of oil is now stored in tanks near the smelter, which will ensure a full fuel supply during the rainy season, the daily consumption being 4000 gal. The concentrating plant is treating 100 tons of ore per day, although its capacity is 600 tons, but the Kennett smelter does not receive concentrate, so this is being stored. Over 150 men are employed, and two shifts are working underground in breaking ore for the Kennett smelter. In December about 30 cars were shipped, the average net value per car being $1000.

Inyo County

During November the mill at the Skidoo mine treated 1096 tons of ore, yielding bullion worth $13,562. Operating costs were $5042, and development $1748, leaving a profit of $6772.

Plumas County

(Special Correspondence.)—Copper-bearing ore is being developed in the Five Bears mine, Genesee district. The main lode ranges from 14 to 20 ft. wide and has been proved to a depth of 900 ft. The company is using electric concentrators, and is preparing to send three cars of concrete per month to custom smelters. The property is credited with a gold output exceeding $20,000 from the surface deposits. Allison & Bluett, of Los Angeles, are working the property under lease and bond. Los Angeles people, headed by Thomas J. Steel, have merged the scattered holdings in the Copper Mountain district into one company. It is planned to drive a cross-cut adit to open the veins at an approximate depth of 1500 ft. Work will commence in the spring. The Engels Copper Co. is reported to have a large reserve of ore blocked out. A small smelter has been erected at Light's canyon. Walker Bros., of Salt Lake City, are actively developing the Walker copper mine. The vein is said to be over 30 ft. wide. The property lies four miles southeast of the Five Bears group. Several other companies are active in the Genesee district, and indications point to a busy season in 1913.

Greenville, December 26.

The Genesee district is well watered by the Indian, Clover, Ward, and Little Grizzly creeks, which are capable of furnishing a total of 3000 to 4000 hp. for mining purposes. The Genesee mine, on Ward's creek, has produced $800,000 in gold from 100-ft. depth.

Sierra County

At the Tightner mine a winze will be sunk about 1000 ft. deep before any lateral development is started. P. Rohrig and Wright Bros. have taken a lease on the gravel section of the Red Star mine, and are preparing to cut the lead from the Cumberland adit. H. J. Langdon has assumed the management of the Sixteen to One mine, and shaft-sinking has been started. The old Arcade property, on Lafayette ridge, which was formerly worked as a gravel mine, has been leased to two Goldfield men.

Shasta County

Seventy mining claim notices were filed on January 1 with the County Recorder. In the Jawbone district 42 claims were located, this being property abandoned by the Kennett Con. Copper Company.

The Railroad Commission has directed that the rate of $11 per short ton of blister copper worth $300 per ton from Kennett to San Francisco by the Southern Pacific Co. is unjust, and reduced it to $6.90 on copper worth $400 per ton.

When driving a tunnel for water-supply near the Big Bend of Pit river, the Northern California Power Co. cut an 8-in. seam of good bituminous coal at 290-ft. depth. This is the first coal found in the district. The seam has been followed 22 ft. and is proving thicker as work progresses. The coal is used in the blacksmith-shop and gives satisfaction.

Tuolumne County

(Special Correspondence.)—Pasadena capitalists have taken a bond on the Omega mine and will visit the property shortly to arrange for its extensive development. It is understood that $50,000 will be expended in exploration. A complete equipment is on the property, including a 20-stamp mill. A 10-stamp mill is being erected at the Atlas mine, near Tuttletown, and the erection of a new hoist and other contemplated structural improvements will soon be under way. John L. Witney is superintendent, and has directed the development of the property ever since work was commenced by the present operators, two or more years ago. The Harvard, near Jamestown, which has been operated continuously for a number of years, holds out promise of producing steadily for a long time to come. About 75 men are at present employed, and the 60-stamp mill is in operation full time. A modern residence for H. W. Gould, the superintendent, is in course of erection at the property. The Gold Ship gravel mine, near Groveland, is being unwatered preparatory to resumption of operations, which ceased a few months ago, owing to the temporary shut-down of the electric plant supplying the power. Gravel was uncovered in the face of the main drift just prior to the recent suspension of operations. It is reported that work may soon be resumed at the Crystalline mine. The Mexican mine, northeast of Jamestown, from which early-day miners took out much gold, has been purchased by H. Cavil, who intends to reopen and develop the property. The Hardtack and Hunter mines, situated a few miles southeast of Tuolumne, and owned by W. T. Carter, are being unwatered for inspection by prospective buyers. Development of the Mangante mine, near Jamestown, is progressing steadily. It is reported that the working force will be increased after a few more weeks of work sinking the shaft. It is reported that a small vein, rich with free gold, has been uncovered in a cross-cut at the Driesam mine, at Arastraville. The 2-stamp mill at the Morning Glory mine, near Confidence, has been started. A drift is being driven from the bottom of the shaft, 100 ft. deep, where the vein is 3 ft. wide. An interest in the property has been purchased by E. W. Burley from Bingham and Layman.

Sonora, December 29.

COLORADO

Clear Creek County

The main cross-cut at the Bard Creek mine is being driven steadily and is in 1100 ft., and within 100 ft. the main lode is expected to be cut. Lessees at the La Plata mine, Democrat mountain, have broken into workings from the Silver Glance shaft. They have been mining ore from a small vein which is yielding 240 oz. of silver per ton. A good year is expected from the Capital mine, and lessees are all doing well.

Shipments of ores by the Colorado & Southern railroad from Black Hawk during the past year were 52,550 tons, to which should be added those sent from mines of Russell gulch through the Newhouse tunnel, and over the Moffat road from the northern portion of the country, making 84,350 tons, as against 76,745 tons in 1911. This

does not include the large tonnage treated in the local stamp-mills. The concentrating plant of the Frontenac-Aduddell syndicate has been in constant operation and treated about 150 tons per day, the ratio of concentration being 4 to 1. The Iron City mill has been busy with custom work. The old Hidden Treasure mill, at Black Hawk, has been purchased by Eastern capitalists, who are overhauling it for custom ore. The U. P. R. and Polar Star mills have had a busy year, and gave satisfactory results. The new shaft of the Square Deal company is down 650 ft., and shipments in December yielded high returns in gold, silver, and copper.

Lake County (Leadville)

Everything points to the past year being a record one for this county, while for the current year it is expected that the downtown section will be unwatered, also that of upper Fryer hill, and several large properties on Carbonate hill. The adit being driven by the Sugar Loaf Consolidated company is now in 4500 ft. The breast is heading northwest, and at this point work is being done on the Emmett claims, and 200 tons of ore per month, averaging 50 oz. of silver and 7% lead, is being shipped.

Mineral County

Fire broke out in the Nelson adit of the Happy Thought mine on December 24, and in order to save the lives of 40 men, rescue parties had to remove 50 tons of ore from an abandoned shaft. They met great difficulties, but all the men were saved.

Teller County (Cripple Creek)

Production of this district for December was as follows:

	Tons.	Av. Val.	Total. Val.
Golden Cycle	31,000	$20.00	$ 620,000
Portland	10,000	22.00	220,000
Smelters	4,000	65.00	260,000
Portland (Victor)	15,000	3.00	45,000
Stratton's Independence	10,000	3.00	30,000
Ajax	3,000	3.25	9,750
Blue Flag	1,000	5.50	5,500
Dante	1,500	3.00	4,500
Wild Horse	1,000	3.80	3,800
Jo Dandy	1,700	2.00	3,400
Isabella	1,000	1.50	1,500
Total	79,200	$15.20	$1,203,450

The Elkton M. & M. Co. produced 2400 tons, averaging $19 per ton. In its interesting special issue of January 1, the Cripple Creek *Times* publishes a great deal of valuable information regarding the district from which the following data are abstracted.

Production by mills in 1912:

	Tons.	Value.
Golden Cycle	381,450	$ 7,663,100
Portland (Colorado City)	119,169	2,617,518
Smelters	46,379	2,989,935
Local plants	350,453	1,086,188
Total	897,451	$14,356,741
Deducted for concentrate re-treated		350,000
Actual production		$14,006,741
Average value of all ore treated		$16.00

Total production to date is $310,354,227.

Output of local mills in 1912:

	Tons.	Av. Val.	Total. Val.
Portland (Victor)	173,079	$ 3.17	$ 548,947
Stratton's Independence	117,429	3.04	356,739
Colburn (Ajax	16,445	3.38	55,527
Kavanaugh (Jo Dandy)	14,450	2.28	33,060
Wild Horse	12,200	3.51	42,860
Gaylord (Dante)	6,400	3.31	21,180
Isabella	5,750	1.45	8,325
Blue Flag	4,700	4.16	19,550
Total	350,453	$ 3.10	$1,086,188

Due largely to the construction of the Golden Cycle mill at Colorado Springs, which handles 75% of the ore shipped from Cripple Creek, the operator and lessee gets a high return from his ore.

Dividends paid during the year were as under:

Cresson Con. G. M. & M. Co. (est.)	$ 500,000
Golden Cycle Mining Co	360,000
Portland G. M. Co	240,000
Vindicator Con. G. M. Co	180,000
Strong G. M. Co. (est.)	150,000
El Paso Con. G. M. Co	123,500
Stratton's Independence, Ltd	120,000
Elkton Con. M. & M. Co	112,500
Mary McKinney M. Co	78,555
Aurarla G. M. Co. and other owners Forest Queen	35,000
Stratton's C. C. M. & D. Co	25,000
Jerry Johnson M. Co	24,979
Gold Dollar Con. G. M. Co	17,500
Little Bessie G. M. Co. (from sale of property)	16,625
Granite Gold Mining Co	16,500
Gold King Mining Co	15,000
Acacia G. M. Co	14,390
Blue Bird G. M. & M. Co	10,000
Maggie Gold Mining Co	9,000
Gold Sovereign M. & T. Co	5,000
	$2,053,549
Lessees' profits (est.)	450,000
Total	$2,503,549

These figures include the dividends of close corporations,

PORTLAND MINE AT CRIPPLE CREEK.

closely estimated; also lessees' profits, as to which the credited total is conservative. The total to date is now $38,128,584.

Hoisting ore has been started at the Nichols shaft of the El Paso mine, which is the new shaft sunk at the east end of the property. Because of the quantity of water flowing through the 1000-ft. level, it will be impossible to clear the shaft below that point of the waste which was left in it after the shaft was raised.

IDAHO

Shoshone County

Over 16 inches of snow fell during the past week, and slides are feared in the Coeur d'Alene. On January 4 the Bunker Hill & Sullivan company paid dividend No. 184, amounting to $65,000, making a total of $13,977,150 to date. The Highland-Surprise Mining Co. has let another contract for driving the adit a further 200 ft. At 3000 ft. from the portal, a 5-ft. vein was cut in the Highland Chief claim. The Palisades company has suspended work for the winter, owing to there being 5 ft. of snow in the district. An adit 3500 ft. long is to be driven when supplies can be obtained next spring. At the Alice mine the 600-ft. level is almost unwatered. About 30 men are employed at present. The Federal Mining & Smelting Co. declared a dividend of $180,000 on December 14, the total for 1912 being $720,000, and $7,361,000 to date. It is stated that the Star mine, adjoining the Morning, has been acquired by the Federal company for $750,000.

MICHIGAN

HOUGHTON COUNTY

The Ahmeek company will send an experimental shipment of mohawkite ore to the Dollar Bay smelter, where a furnace is being specially constructed to treat this ore. It has never been smelted in the Lake Superior region before, but satisfactory results are expected. The Ahmeek mine can supply a large tonnage of mohawkite which carries a high percentage of arsenic. When first found it was treated at a smelter in New Jersey, but freight consumed most of the profit.

MISSOURI

JASPER COUNTY

The mineral output from the Joplin district for the year 1912 was valued at $18,149,777, being about $5,000,000 greater than 1911, and was due to the heavy production of zinc ores. The following is a detailed statement of production.

	Missouri.	Kansas.	Oklahoma.	Total.
Blende, lb.	494,430,190	45,119,460	21,054,084	560,603,734
Calamine, lb.	39,382,840	225,040	4,260	39,612,140
Lead, lb.	78,011,390	6,598,570	7,992,240	92,612,300
Value	$15,021,415	$586,113	$2,542,249	$18,149,777

An idea of the present effort to prospect the district may be gained from the fact that one operator has 30 separate rigs in operation.

MONTANA

LEWIS AND CLARK COUNTY

Development at the North Moccasin property of the Barnes-King company has exceeded expectations, and the Santiago orebody has been opened through the old Barnes-King workings. At the Piegan-Gloster property the Ophir adit has been driven on the vein and has produced some low-grade ore, but before the end of January the adit should cut the vein which has been opened in the Piegan district, 125 ft. above. The latest report states that it is 6 ft. wide and payable. On December 14 the Barnes-King mill was started, and is treating 100 tons per day, but will be brought up to its 200-ton capacity as soon as the mine stopes are ready. Assays so far return $7.60 to $8.80 per ton. It is not expected that the orebody will average as high as this, as the average of 25,000 tons mined by the former management was $5.60 per ton.

NEVADA

ESMERALDA COUNTY

On the 1300-ft. level, and below this point, in the Grizzly Bear workings of the Goldfield Consolidated, ore containing silver and copper has been opened. This is not amenable to ordinary treatment, and the matter is under discussion. For some time past, certain ore has been shipped to the Tooele smelter in Utah. Apart from the condition of the Consolidated mines, the current year is expected to be satisfactory at the other mines in the Goldfield district.

LYON COUNTY

Steam-shovels are to be used at the Mason Valley mine and preparations are being made for them. It is believed that when the capping of the orebodies is removed, the ore can be mined for a considerable depth by this method. The McConnell mines have given up using the auto truck, as it cost $100 per week for tires alone. The truck was a 50-ton automatic dumping type. The Nevada-Douglas Copper Co. produced about 11,000,000 lb. of copper in 1912.

NYE COUNTY

Competition in milling at Manhattan has resulted in a reduction in charges on custom ores, which makes it possible to have low-grade ore treated at a profit. There are three 50-ton custom mills in the market for ore, and rates at present are from $3.75 to $4.50 per ton for hauling and treatment, against $10 to $12 per ton charged over two years ago, with only one mill at work. During 1912 the following was the production of Manhattan as compiled by the Manhattan *Post:*

	Tons.	Value.
War Eagle	10,800	$196,109
Associated	9,825	158,000
Priest (Poak lease)	4,500	55,000
Manhattan M. & O. Co.	2,140	19,122
Total from ore treated	27,265	$428,231
Output of placers		200,000
Total from all sources		$628,231

With the starting of the Big Four mill in a short time, the current year will show a much greater output and rapid progress is expected.

The Tonopah *Miner*, with its usual promptness, publishes

TONOPAH.

the output of the Tonopah district for the past year as follows:

	1911. Tons.	1911. Value.	1912. Tons.	1912. Value.
Tonopah Mining	173,600	$3,572,000	173,809	$ 3,215,460
Belmont	114,500	3,091,500	123,847	3,149,580
Tonopah Ex.	51,000	663,000	53,201	731,513
Montana	52,500	761,250	51,875	1,023,500
West End	13,350	318,750	41,081	824,820
MacNamara	1,000	27,250	20,195	252,437
Midway	2,100	52,500	1,001	46,792
North Star	....	.....	500	19,375
Jim Butler	....	.....	6,088	133,900
Tonopah Merger	....	.....	1,485	33,005
Mizpah Ex.	....	.....	30	1,221
Total	408,140	$8,486,250	473,112	$ 9,431,603
Increase	....	.....	64,972	945,353
Total to date				58,144,490

Dividends:

	1911.	1912.	Increase.
Tonopah Mining	$1,600,000	$1,600,000	.....
Tonopah Belmont	1,350,000	1,500,000	$150,000
Montana Tonopah	110,623	199,786	89,163
Tonopah Extension	.....	47,500	47,500
Total	$3,060,623	$3,347,286	$286,663
Total to date		$15,503,559	

Dividends to be paid in January amount to $798,750 and will swell the total.

UTAH

Dividends paid by Utah mines in 1912 were: Bingham-New Haven, $68,607; Cliff, $30,000; Colorado, $90,000; Consolidated Mercur, $30,000; Daly-Judge, $225,000; Daly West, $216,000; Gemini, $30,000; Gold Chain, $70,000; Grand Central, $50,000; Iron Blossom, $370,000; Mammoth, $60,000; Opohonga, $57,396; Silver King, $312,500; Utah Copper, $4,933,282; Utah Consolidated, $450,000; and United States Smelting, $2,490,926.

SALT LAKE COUNTY

During the past year the mines at Bingham produced 6,650,345 tons of copper ore, and only for the miners' strike the total would have been over 7,000,000 tons. The total tonnage to date is 27,016,998 tons.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

A. K. Beatson is in San Francisco.

F. L. Sizer has returned to Arizona.

C. S. Herzig is in Western Australia.

C. F. Spaulding is here from Denver.

J. W. Abbott was here during the week.

Z. Cushing has returned from Honolulu.

F. B. Weeks has gone to Shasta county.

Edmund Juessen is in southern California.

C. T. Durell was in San Francisco this week.

P. B. McDonald is now at Gouverneur, New York.

Ralph Arnold was in San Francisco New Year's day.

William A. Paine has gone to Bermuda for a few weeks.

George H. Garrey has returned to New York from Arizona.

C. B. Lakenan was married recently to Mrs. Floribel White.

Harry R. Johnson has returned from London to Los Angeles.

H. F. M. Crookshanks has gone to Oaxaca on professional business.

M. P. O'Brien is at the Nonesuch mine, Ontonagon county, Michigan.

A. J. Robin has taken over the business of Herr & Herbert, at Durango.

M. K. Shaler is visiting Italy, but will be in Brussels for the next year.

E. J. Collins has returned to Duluth from professional work in Colorado.

F. G. Lasier, of Detroit, will be in the Cripple Creek district during January.

Desaix B. Myers is returning to Los Angeles from Butte, stopping at Nelson, Nevada.

Brayton P. Campbell is now superintendent for the Potrero Mining Co., Mocorito, Sinaloa.

H. C. Hoover has gone to London, expecting to return to San Francisco in three or four months.

H. P. Gordon has returned to Oakland after a year spent in hydraulic mining in eastern Canada.

W. T. Perkins has been elected chairman of the Alaska bureau of the Seattle Chamber of Commerce.

Henry E. Wood is visiting Pittsburg, New York, and Boston, returning to Denver about January 20.

A. L. Wilcox is in charge of the hydro-electric power development at Oroya, Peru, for the Cerro de Pasco Mining Company.

Myron L. Fuller has completed an investigation of the water resources of the Livermore valley for the city of San Francisco.

Howland Bancroft is engaged in examination work in western Nevada and expects to return to Denver at the end of the month.

Robert E. Cranston sailed from New York on December 28 for Brazil. His address there will be Caixa Postal 834, Rio de Janiero.

Robeat Scott is at Beatty, Nevada, where he is building a quicksilver plant for the Telluride Consolidated Gold Mines, Limited.

Kosaku Asano, metallurgist for the Ashio smelter, who is visiting metallurgical plants in America, was in San Francisco during the week.

Teisaburo Hori, formerly general manager of the Ikuno mine of the Mitsu Bishi company, has been at Goldfield and has gone to Salt Lake City.

Market Reports

New York Metal Prices, December, 1912

In the course of December spelter dropped from 7.50c. New York to 7.30c. per lb., and at the latter price was weak. The market was dull during the entire month, and the decline started in early. In view of the dullness it is considered that the prices of spelter have held very well indeed. About the middle of the month a few cars of good brass mill spelter were sold at a price approximating that of prime western, the producers preferring to sell at what seemed a sacrifice rather than carry the metal over 1913. The prices in the closing days of the month were 7.30c. N. Y. and 7.15c. E. St. Louis, and these prices subject to shading.

The price of lead was cut again on December 3 from 4.50c. to 4.35c. lb. by the American S. & R. Co. Outside sellers met the cut and offered lead at 4.35c. N. Y. and 4.22½c. E. St. Louis. The market continues weak and three reasons are given for the situation—light demand, sharp competition, and fear of tariff changes. A development of importance to the trade and to all concerned is an organization formed by lead consumers who propose to secure, if possible, a lower tariff on pig lead and other metals. Those active in the new organization are working quietly but energetically to interest other consumers. Just before Christmas it was evident that consumers were taking a greater interest in lead, but their inquiries had not developed into any substantial buying. On December 24 prices were 4.27½c. per lb. N. Y. and 4.12½c. E. St. Louis, these prices of course, being quoted by 'outsiders.'

In December the tin market was featureless at first, and the activity exhibited was of the spasmodic kind. About December 12 a more or less steady buying set in and while good, it was curtailed by the high prices. December 17 tin sales were made at 50c. per lb., on December 23 at 50.25c., and December 24 at 50.15c., despite the fact that consumers do not take kindly to the 50c. level. The lowest price of the month was 49.25c. per lb., which ruled on several days. The latter part of the month there was something of a shortage of spot tin which in part caused the high prices, but the arrival of steamers in the early part of January will bring the pinch to an end. December 27, arrivals were 3549 tons, with about 200 more tons to be landed in the month. On that day there was afloat 1096 tons.

Record Year in Zinc

The valuation of zinc and lead ores from the Missouri-Kansas-Oklahoma area for 1912 is $18,043,379, or more than $2,500,000 greater than the record of 1907. High prices for zincblende, which at times brought as much as $67 per ton on an assay basis of $64 for grades carrying 60% metallic zinc, were responsible for the good showing. Almost every district in the area showed a big increase over the previous year and several new districts made their appearance. Prices for calamine were exceptionally high throughout the year. Lead was the only ore to be in weak demand. Prices were low and as a result shipments were lighter than might otherwise have been expected. The new year dawned with conditions more auspicious than they have ever been at the opening of a year. The above table shows the production, in pounds, of blende, calamine, and lead, from the various districts of the area, together with the valuations.

PRODUCTION OF LEAD AND ZINC ORES, MISSOURI-KANSAS-OKLAHOMA.

Spelter Production in 1912

Production.—The production of primary spelter from domestic ore in 1912 is estimated by C. E. Siebenthal of the U. S. Geological Survey, at 323,961 short tons, and from foreign ore at 14,669 tons, a total of 338,630 tons, worth, at the average St. Louis price, $46,731,000, compared to a total of 286,526 tons in 1911, worth $32,663,964, and made up of 271,621 tons of domestic origin and 14,905 tons of foreign origin. The production of spelter from both domestic and foreign ores, apportioned according to the states in which it was smelted, by six-month periods, was:

SPELTER PRODUCTION, 1911-1912, BY STATES

State.	1911. First half.	1911. Second half.	1912. First half.	1912. Second half.
Illinois	41,255	41,875	44,224	44,065
Kansas	50,574	47,839	52,485	48,376
Oklahoma	19,997	26,318	36,010	41,584
Other states	28,370	30,298	33,777	38,109
Totals	140,196	146,330	166,496	172,134
Yearly totals	286,526		338,630	

The total production of spelter is equivalent to the output of 79,678 average retorts operating continuously through the year on 60% zinc concentrate. The retort capacity, available for ore, of the plants active in 1912 was, at the beginning of the year, 80,200 retorts. Many of them, of course, were used on low-grade ores, lessening their capacity. To these were added during the year 19,848 retorts, of which 2880 were in Pennsylvania, 3456 in West Virginia, 2476 in Illinois, 10,796 in Oklahoma, and 240 in Colorado. Meanwhile there were slight reductions in capacity at certain plants, so that the total number of retorts at the close of 1912 was 99,400. In Illinois there are now nearing completion 2400 retorts at the new Hillsboro smelter of the American Zinc Co. of Illinois, which started with 1600 retorts in November; 1600 retorts at the plant of the R. H. Lanyon Zinc & Acid Co., also at Hillsboro, which will start early in 1913; 1800 retorts at the plant of Hegeler Bros., at Danville; and 4560 retorts at the Mineral Point Zinc Co.'s smelter at Depue. In Kansas 576 retorts will be added to the La Harpe plant of the Kansas Zinc Co. Oklahoma now holds first place in active smelting capacity, with 27,416 retorts; Kansas is second, with 27,092 retorts; and Illinois third, with 25,148 retorts. The largest smelter is the Collinsville (Oklahoma) plant of the Bartlesville Zinc Co., with 8064 retorts; the next largest is the Meadowbrook (West Virginia) plant of the Grasselli Chemical Co., with 6912 retorts; and the third is the Collinsville (Oklahoma) plant of the Tulsa Fuel & Manufacturing Co., with 6232 retorts. The Mineral Point Zinc Co.'s plant at Depue, Illinois, will have 9080 retorts when completed in 1913.

At the close of the year the National Zinc Co. took over the United Zinc & Chemical Co.'s plants, consisting of a zinc smelter with 3680 retorts and an acid plant at Springfield, Illinois, and roasting furnaces and an acid plant at Argentine, Kansas.

Imports and Exports.—Imports of zinc ore were approximately 78,000 short tons, containing about 31,500 tons of zinc, compared with 78,341 tons of ore containing 31,640 tons of zinc, imported in 1911. The figures for 1912 are exclusive of 18,245 short tons of lead ore from South America, containing 2431 tons of zinc, an average of a little more than 13%, all of which was lost in smelting the lead and thus does not properly enter into the figures of imports of zinc. Of the zinc ore imported, 72,000 tons, about 92%, came from Mexico, compared with 75,982 tons imported from Mexico in 1911. The exports of domestic zinc ore were 19,953 short tons, valued at $704,207, compared with 18,281 tons in 1911.

The imports of spelter were the largest for many years, being estimated at 10,700 short tons, valued at about $1,202,000, compared with 609 tons in 1911. The imports of zinc dust were 2350 short tons, valued at $262,700, against 1713 tons in 1911. Exports of domestic spelter are estimated at 6673 short tons, worth $871,479, compared with 6872 tons in 1911. The exports of foreign zinc increased from 4758 short tons in 1910 to 11,276 tons in 1911, and to approximately 6779 short tons in 1912. During the first nine months of the year there were also exported under drawback articles manufactured from 938 tons of foreign zinc on which duty had been paid, compared to 3079 tons in 1911. The exports of zinc dross amounted to 203 short tons, valued at $17,803, compared with 4246 tons in 1911.

Consumption.—The apparent domestic consumption of spelter in 1912 may be computed as follows: The sum of stock on hand at smelters at the beginning of the year, 9081 tons, plus the imports, 10,700 tons, and the production, 338,630 tons, gives the total available supply, 358,411 tons. From this there are to be subtracted the exports of domestic spelter, 6673 tons; the exports of foreign spelter, 6799 tons; and the stock on hand at smelters at the close of the year (to be exact, on December 15), 4208 tons; a total of 18,618 tons; leaving a balance of 339,793 tons as the apparent domestic consumption. This calculation takes no account of the stocks of spelter held by dealers or consumers. On comparing the consumption in 1912 with the 280,059 tons consumed in 1911, the 245,884 tons in 1910, the 270,730 tons in 1909, the 214,167 tons in 1908, and the 226,969 tons in 1907, it is seen that the consumption is phenomenally large.

Lead Production in 1912

Production.—The total production of refined lead, desilverized and soft, from domestic and foreign ores in 1912, according to an estimate compiled by C. E. Siebenthal of the U. S. Geological Survey, was approximately 480,965 short tons, worth at the average New York price $43,286,850, compared to 486,976 tons in 1911 and 470,380 tons in 1910. These figures do not include an estimated output of 13,384 tons of antimonial lead, against 14,078 tons in 1911 and 14,069 tons in 1910. Of the total production, desilverized lead of domestic origin, exclusive of desilverized soft lead, is estimated at 229,765 tons, against 201,223 tons in 1911; and desilverized lead of foreign origin comprised 81,649 tons, compared to 94,143 tons in 1911. The production of soft lead, mainly from Mississippi Valley ores, is estimated at 169,551 tons, compared to 191,619 tons in 1911. Despite the reduced output of soft lead, there is no doubt that Missouri retains first place among the lead-producing states. The final figures of production of soft lead are likely to show an increase of a few thousand tons over those given above, because the argentiferous lead smelters and refineries undoubtedly treated more or less soft-lead ore from the Mississippi Valley which is not taken into account in their preliminiary estimates.

Imports and Exports.—The imports of lead are estimated at 10,969 short tons of lead in ore, valued at $452,650; 76,468 tons of lead in base bullion, valued at $3,452,750; and 266 tons of refined lead, having a value of $20,000; a total of 87,703 tons, compared to 89,952 tons in 1911. Of the 1912 imports, 85,000 tons, or about 97%, came from Mexico. The exports of foreign lead (lead of foreign origin smelted or refined in the United States) show a decrease of more than a third, being estimated at 65,253 tons, against 101,227 tons in 1911. The imports of type metal (antimonial lead) were 757,375 lb., containing 485,596 lb. of lead and valued at $18,516, compared with 8,390,470 lb. in 1911, containing 6,936,711 lb. of lead and worth $310,658. These imports of type metal are withdrawn from bond and therefore should not be added to the general imports of lead given above, as that would involve duplication.

Consumption.—The amount of lead available for consumption during 1912 may be estimated by adding to the stock of foreign lead in bonded warehouses at the beginning of the year (4481 short tons) the imports (87,703 tons) and the domestic production (399,316 tons), making an apparent supply of 491,500 tons. From this is to be subtracted the foreign lead exported in manufactures under drawback (estimated at 9848 tons), the deduction by liquidation (5814 tons), and the stock in bonded warehouses at the close of the year (assumed to be the same as at the close of November, 9497 tons), leaving as available for consumption 401,088 tons, which by comparison with 399,472 tons in 1911, 376,021 tons in 1910, and 370,013 tons in 1909, seems to be a normal figure.

The foreign lead remaining in warehouse at the close of November 1912 was distributed principally as follows: At Chicago, 161 short tons, compared with 477 tons at the close of 1911; at Newark, 591 tons, against 1389 tons at the end of 1911; at Perth Amboy, 8353 tons in 1912 and 1154 tons in 1911; and at El Paso, 343 tons, compared with 1278 tons at the close of the preceding year.

The past year has been marked by steady progress in the mining industries of eastern Canada, and a large increase in the value of the output. There have been great advances made in the introduction of improved machinery and more economical processes. The speculative feature, so prominent in the earlier history of the Cobalt and Porcupine districts, has been largely eliminated, and while many of the weaker companies have discontinued operations, the really substantial and well managed enterprises have had a highly prosperous year, and paid good returns to their shoreholders.

Metal Production of Western States

ARIZONA experienced in 1912 an exceptionally good year in mining, especially in the mining of copper ore, and the preliminary total value of all metals is estimated by members of the staff of the U. S. Geological Survey at more than $65,000,000, an increase of more than $20,000,000, or 49% above the production for 1911. Of this total value, the copper output represented over $58,000,000, gold $3,500,000, and silver $2,000,000. Gold production increased 3%, the total being over 17,000 oz. Silver production increased to 3,300,000 oz., or 2%. Copper production reached 359,000,000 lb., an increase of 17% over 1911. The lead output was 7,000,000 lb., a decrease of 32%. Spelter production was 8,500,000 lb., an increase of 89% over 1911.

CALIFORNIA shows an increase in output of both gold and silver in 1912 compared with 1911, according to preliminary figures by Charles G. Yale. The difference is not very marked, but is sufficient to show that the precious-metal output of the state is advancing somewhat. California retains first rank in gold output, regained from Colorado in 1911. The mine figures of the Survey for 1911 were: gold valued at $19,738,908 and 1,270,445 oz. of silver, while estimates for 1912 indicate an output of gold valued at $19,950,000, and 1,270,000 oz. of silver. Moreover, it is highly probable that when complete detailed returns are available, the 1912 figures will be somewhat enhanced. Copper production shows an increase over 1911, though figures are not yet available. Lead shows a decrease, preliminary returns indicating 1,032,000 lb., as compared with 1,398,111 in 1911. Zinc shipments have been at about the same rate as in 1911, when 2,800,000 lb. was produced.

COLORADO mines for eleven months of 1912 and an estimate for December, according to preliminary figures by Charles W. Henderson, show a decrease of $300,000 for gold, an increase of 750,000 oz. for silver, a decrease of 1,000,000 lb. for copper, an increase of 5,000,000 lb. for lead, and an increase of 27,000,000 lb. for zinc. With increased market prices for silver, copper, and zinc, the value of the output in 1912 was over $4,000,000 greater than in 1911—$3,000,000 in zinc and $1,000,000 in silver, the increased value for lead and copper about balancing the decrease for gold. The output for 1912 is therefore estimated at approximately $18,700,000 in gold, 8,080,000 oz. of silver, 7,025,000 lb. of copper, 74,680,000 lb. of lead, and 121,600,000 lb. of zinc, valued in all at nearly $36,500,000.

IDAHO metal output in 1912, according to preliminary estimates by C. N. Gerry, was valued at nearly $21,000,000, an increase of about 10% over the value for 1911. Increases were made in the production of copper, lead, and zinc, while the output of gold and silver slightly decreased. The added value was due partly to the better prices for silver, copper, and zinc prevailing in 1912. There was a slight decrease of about 4% in gold production, lowering the output for 1912 to about $1,300,000.

MONTANA metal output, as a result of the increased prices of metals and the greater production of copper particularly, was worth close to $64,000,000 in 1912, according to preliminary estimates by V. C. Heikes. This represents an increase of nearly 36% in value over the 1911 output and is the most valuable production since that of 1906. About 79% of this value came from copper alone, about 12% from silver, nearly 6% from gold, and nearly 3% from zinc. An estimated decrease of over 3% in gold production brought the output of 1912 down to about $3,500,000. This was probably due to a diminished yield of mill bullion, especially in the Little Rockies district, formerly in Chouteau county but now in Blaine county. The gold-output from placer bullion slightly increased, being sustained by six operating dredges. The four boats at Ruby had a successful season, and the Kansas City plant in Missoula county, and the Magpie in Lewis and Clark county were active. There was also an increase of about 5% in silver, from nearly 12,000,000 oz. in 1911 to about 12,500,000 oz. in 1912. This was creditable to Butte copper ore. The increase of 7.5c. per oz. in the average price of silver meant a difference of nearly a million dollars in the value of the production, while the increased price of copper swells the total.

NEVADA ores, according to preliminary figures by V. C. Heikes, produced metal valued at nearly $36,500,000, which is a little over 7% greater than the value for 1911. The gold output forms the largest part, or 37½% of the total value; copper nearly 34½%, silver slightly in excess of 23%, and lead and zinc each over 2%. The Goldfield mines produced more ore but less gold in 1912, and this with decreased output from the National and Seven Troughs districts was the principal cause of a decrease in total gold production of about 25% from the yield of $18,193,397 in 1911. There has been a steady increase in the annual silver output of Nevada since 1901, when production began at the Tonopah mines. In 1912 the producers of Tonopah increased the yield of ore from about 8000 to nearly 12,000 tons per week, but the average silver content per ton decreased. An increase estimated at 17% in the production of copper, from 67,377,518 lb. in 1911 to about 79,000,000 lb. in 1912, is due to the new smelter which started operations early in 1912 at Thompson on copper ores produced chiefly from the Mason Valley and Nevada Douglas properties in the Yerington district.

NEW MEXICO mine production of gold in 1912, according to preliminary estimates by Charles W. Henderson, showed a small increase over the output of $762,808 in 1911; the output of silver an increase of about 150,000 oz. over the production of 1,354,540 oz. in 1911; lead an increase of about 1,700,000 lb. from the yield of nearly 3,000,000 lb. in 1911; and copper an increase from 4,057,040 lb. in 1911 to about 28,000,000 lb. in 1912. The output of zinc made little change in 1912 from the output of 10,237,176 lb. in 1911. The increase in the value of copper alone adds over $4,000,000 to the value of the output of New Mexico.

OREGON metal output has been declining for several years, more especially in gold and silver, but preliminary returns for 1912 show that this has now been checked, according to Charles G. Yale. The mine report of the Survey for 1911 showed an output of gold valued at $633,407 and 45,221 oz. of silver. The preliminary returns for 1912 indicate that the Oregon yield was about $657,000 in gold and 86,951 oz. of silver, a marked advance in the silver output. Moreover, the smelters received about 100,000 lb. of copper, compared with 93,196 lb. in 1911, and 38,000 lb. of lead, whereas there was no yield of lead in 1911. More placers are being worked than formerly in Oregon, mainly by hydraulic methods. The grade of ore in the deep mines has been much lower than formerly, although more of it is treated. The lowering of the average tonnage value is due to the large quantities of old tailing handled, their average yield being taken with that of the new ore in making up the totals and average values.

SOUTH DAKOTA mine production of gold in 1912, according to preliminary estimates by Charles W. Henderson, was the largest ever produced in any one year, the output being $150,000 above the previous maximum mine yield of $7,657,376 in 1908, or about $7,807,000 in 1912. The yield of silver showed little change. Both lead and copper were produced in 1912, the output for each metal being close to 20,000 pounds.

UTAH ore production in 1912 aggregated close to 7,500,000 tons, valued at about $44,000,000 for its gold, silver, copper, lead, and zinc content, or an increase of 19%, according to preliminary figures by V. C. Heikes. The strike of miners at Bingham, lasting 40 days, during which nearly all the mines there were closed or operating with decreased forces, caused a decrease of about 500,000 tons in the total ore production. The smelters, however, were not seriously affected, as they operated for a time on the stock reserves and at nearly full capacity the entire year. Owing to the higher price paid for the metals, considerable old mine-dump material on various properties, the accumulation of many years operations, was almost entirely disposed of to the smelters, and likewise large dumps of old slags were shipped for re-treatment without sorting.

WASHINGTON gold production decreased to about $679,000 in 1912, according to preliminary figures by C. N. Gerry. The total value of all metals produced in the state was greater by nearly 7% than that of 1911. This was due to

the increased production and better market price of both silver and copper. There were no shipments of zinc ore, and only a few cars of lead ore was marketed, against a nominal output of zinc and a production of 848,584 lb. of lead in 1911.

Review of Lake Superior Copper Mining Industry, 1912

By R. H. Maurer

Mining for copper in the Lake Superior district antedates the earliest visits of European explorers to this region, and begins with production on a commercial basis in 1845, since when the district has been a steady producer. Always an important factor in the copper-mining industry of the world, the Lake Superior field for many years subsequent to 1845 was the most important copper-producing district in the United States. In total production, the Lake Superior district ranks second, and in output for 1912 it ranks third. The total production of fine copper to the close of 1912 is estimated at approximately 5,200,000,000 lb.—30% of the output from the United States since 1845.

Although an English company made an attempt at mining along the Ontonagon river, in the southern part of this district, as early as 1770, the history of copper-mining in historic times may be said to begin with the organization, in 1844, of the Pittsburgh & Montana Mining Co., the first producer and also the first dividend-payer of the district. This company operated the famous Cliff mine of early days. The first dividend of which there is any record was paid by the Old Cliff in 1849, the amount being $60,000. Dividend payments during 1912, with eight companies contributing, reached a grand total of $9,069,257, an increase of nearly $3,000,000 over the preceding year.

In the value of metal output, and in the resulting profits, the district takes high rank among the great mining fields of the world. The gross value of production to date will closely approximate $800,000,000, and the total dividend disbursements by all companies now stands at above $200,000,000. Though primarily a producer of copper, the Lake Superior district has at various times yielded considerable quantities of silver, and in 1911 ranked eighth among the silver-producing states of the Union with a production of 497,281 fine ounces of silver, against 330,500 oz. in 1910. Production in 1912 will probably exceed 500,000 oz. This production is secured mainly from the electrolytic refining of the copper produced, and, as a rule, increases or decreases as the quantity of copper refined is increased or reduced.

Dividend disbursements by Lake Superior companies during the past year, and total payments of all companies for all years of which there is any record are shown in the appended table.

Company.	1912.	Total.
Ahmeek	$ 900,000	$ 1,000,000
Atlantic	.....	990,000
Calumet & Hecla	4,200,000	119,100,000
Central	.....	2,130,000
Cliff	.....	2,518,620
Copper Falls	.....	100,000
Copper Range Con	787,382	12,901,048
Franklin	.....	1,242,000
Kearsarge	.....	160,000
Minesota	.....	1,820,000
Mohawk	350,000	2,650,000
National	.....	320,000
Osceola	1,201,875	11,266,250
Pewabic	.....	1,000,000
Phoenix	.....	20,000
Quincy	550,000	20,292,500
Ridge	.....	100,000
Tamarack	.....	9,420,000
St. Mary's	480,000	5,560,000
Wolverine	600,000	7,440,000
Total	$9,069,257	$200,030,418

The growth of the industry has been remarkable, and, although the district has been an active producer for more than 65 years, none of the mines are threatened with immediate exhaustion. Less than 30% of the copper-bearing area has been touched, and the productive limit of the district appears nowhere to have been reached. Production, which in 1845 amounted to only 25,000 lb., increased by leaps and bounds to more than 200,000,000 lb. in 1904, and reached its high mark in 1905, the total output in that year amounting to 230,288,000 lb. fine copper. The annual rate of production since 1907 has held steadily around 220,000,000 lb., and at no time declined more than 5% from the high mark set in 1905.

Much attention was paid during 1912 to the exploitation of new territory, and this work has added much to the known mineral resources of the district. Nearly $1,000,000 was required to meet the cost of this exploratory work by companies still in the development stage. More than 30 companies were actively engaged on both ranges seeking workable copper deposits or developing deposits disclosed in previous years. Of the several new disclosures of copper deposits made at various points along the contact of the Lake Superior mineral belt with the great Eastern Sandstone, those in the area under development by the Mayflower and Old Colony companies are easily the most important. The south range, which was quite thoroughly explored in the preceding year, continues to receive full attention.

The number of workers employed in the various branches of the industry was again smaller than during the preceding year and is now around 17,000, compared with 18,000 a year ago and 21,000 employed in the three counties in 1909. Fully 15,000 find employment in Houghton county. The payroll of the district will closely approximate $15,000,000 per year. A brief résumé of what the several Lake Superior companies accomplished during the year, and what may be expected in the future, follows:

The Calumet & Hecla Mining Co., with probably less than 20 years of life remaining in the conglomerate lode, is concerned chiefly with the development of the Osceola lode on its own property, and with the development of a number of mines on other formations, in which the company is interested through its shareholdings in other companies. The conglomerate bed has been a most profitable source of production, and will continue to be so to the end of its life, though declining copper content has materially affected profits. The mine in the conglomerate lode is supplying about three-fourths of the Calumet production, about 2,000,000 tons of ore per year, averaging around 30 lb. fine copper per ton. There remains approximately 30,000,000 tons unmined. The mine on the Osceola lode, easily capable of supplying 1,000,000 tons per year, is low grade, with a copper content of about 15 lb. per ton of rock. The reserve of the mine on this formation is estimated at 40,000,000 tons. The combined output of these mines during the year closely approximated 2,700,000 tons, resulting in a production of slightly more than 69,000,000 lb. fine copper, indicating an average yield of about 26 lb. fine copper per ton of rock milled. In addition to the output secured from the Calumet and Osceola lodes, the company controls the sale of upward of 60,000,000 lb. fine copper produced by the so-called Calumet & Hecla subsidiary companies, giving the parent company a total output well over 130,000,000 lb. fine copper annually, or approximately 60% of the total output of the Lake Superior district.

The Copper Range Consolidated Mining Co. is not directly engaged in mining, but is a securities-holding company controlling and directing the operations of the Baltic, Champion, Trimountain, and Atlantic mines, and the Copper Range railroad. These mines during the year yielded approximately 37,300,000 lb. fine copper. In this production the St. Mary's Mineral Land Co. has an equity equal to about 8,000,000 lb., being one-half of the output of the Champion mine, owned jointly by these companies, leaving the consolidated company a net production of about 29,000,000 lb. This production was taken from the Champion, Baltic, and Trimountain mines. The Atlantic mine is idle. The Baltic and Champion mines are the mainstay of the combination and show no appreciable changes

from the previous year, physical conditions being entirely satisfactory. The Trimountain mine has improved wonderfully during the year and promises to take equal footing with its big neighbors. Production has increased materially within recent years and was fully 20% greater than in the preceding year.

The Quincy Mining Co. will, when final figures are in, report a production smaller by about 5% than that of the preceding year. Dividend disbursements were greater by nearly $500,000. The mine is old and deep in the south end. Air blasts are of frequent occurrence, but are not proving so troublesome as in the past and do not greatly hinder operations. The Quincy is no longer the rich mine it once was and the content, as in all other Lake Superior mines, has declined materially with depth. The present yield will range between 14 and 16 lb. fine copper per ton of ore mined, averaging 15 lb. Development work is confined almost entirely to the so-called Pontiac tract in the extreme north, in which a shaft has been sunk to a depth of 3000 ft. Despite the long life spent on the Pewabic lode the company has in the north territory, embraced by the Mesnard, Pontiac, and St. Mary's tracts, an area fully as great as that already worked out in past years.

The Osceola Consolidated Mining Co. operated with much the same results obtained in past years and is keeping ore reserves well ahead of immediate requirements. Production was smaller by about 300,000 lb. Striving for 'dollar rock,' the company has probably come closer to attaining this object than has any other mine in the district. The cost of mining, transporting, and milling a ton of ore during the past year will probably average less than $1.25. Its ability to show such remarkably low operating costs is in part due to the favorable physical condition of the property, but is withal an achievement that evidences good management. The Osceola branch was reopened during the year and is now yielding a regular production. The Ahmeek Mining Co. continues to establish new records. Production increased fully 1,000,000 lb., with costs reduced to about 7½c. per pound, making the mine the champion low-cost producer of the district. A total of $900,000 in dividends was disbursed during the year.

The Wolverine Copper Mining Co. reports a normal production, with dividend disbursements slightly increased. The company has an estimated life of 7 to 9 years on the Kearsarge lode. Considerable attention was paid to exploratory work in the horizons of the Osceola and Old Colony lodes. This work offered some promise, but is generally without encouragement. The Mohawk Mining Co. in strengthening its position among the dividend-payers, and its ability to wring profits from the treatment of the low-grade copper ore reflects great credit on the management. Production holds steadily around 12,000,000 lb. annually. The physical condition of the property is excellent and a larger production is predicted for the new year.

Isle Royale, Allouez, Superior, and Tamarack are profitable producers, with productions ranging from 8,000,000 lb. down to 4,000,000 lb. annually. The Isle Royale will probably declare its first dividend early in the new year. The others may be expected to follow a year or two later in the order named. Isle Royale, the largest producer of the quartette, is sinking a new shaft and will shortly be in position to increase production to around 12,000,000 lb. annually. Allouez is operating through two shafts with an annual production of 10,000,000 lb. fine copper in sight. Superior is developing an area of exceptional richness in the west bed of the Baltic formation, but is still a one-shaft mine. Development work in the south shaft continues rather discouraging. Tamarack is centring activity in the Calumet conglomerate, and is also giving some attention to the underlying Osceola lode. The mine is seemingly hopeless. It is a deep mine and the cost of production is very high. The mine is practically on probation and will never again be the Tamarack of old.

In quite another class are the Lake, Hancock, Franklin, Centennial, Mass, Winona, and Victoria. All are yielding small productions and all are still in the development stage. Years will be required to place even the most likely on a dividend basis. The worth of the Lake with respect to the Lake lode has been fairly demonstrated. The possibilities on the several other formations in its territory are unknown. Hancock has developed several copper deposits of commercial value and will be yielding a regular production early in the present year. Franklin has one shaft in operation and a second under way. Production increased fully 100% during the year and promises to reach a total of 3,000,000 lb. during 1913. The corner has been turned after years of discouraging work and the mine is going to be one of the largest in this district. The Winona is making slow progress. Two shafts are in commission. A large tonnage of low-grade material has been developed and the mine is easily capable of doubling the present rate of production. Centennial, Mass, and Victoria are obtaining just enough encouragement to induce further work. The Laurium, Houghton, Objibway, St. Louis, Oneco, Wyandot, and White Pine are engaged in development work with varying degrees of success. The Indiana, Adventure, New Baltic, Algomah, New Arcadian, and South Lake are sinking shafts and otherwise opening ground for the purpose of determining the value of copper deposits previously disclosed in diamond-drilling. Mayflower, Old Colony, Naumkeag, Onondaga, La Salle, Keweenaw, and Contact confined all activity to diamond-drilling, work that resulted most favorably for Mayflower and Old Colony. The Gratiot, Michigan, North Lake, and Bohemia, all active in 1911, spent the greater part of 1912 in idleness.

Copper Production in 1912

The figures showing smelter production from domestic ores, which have been collected by B. S. Butler, of the U. S. Geological Survey, represent the actual production of most of the companies for eleven months and an estimate of the December output. The November figures for a few companies were not available and these companies furnished estimates for the last two months of the year. According to the statistics and estimates received, the output of blister and Lake copper was 1,249,000,000 lb. in 1912, against 1,097,232,749 lb. in 1911, at an average price of 16c. per pound the 1912 output has a value of nearly $200,000,000, against $137,154,092 for the 1911 output. Statistics for December appear elsewhere.

Statistics published by the Copper Producers' Association show an output of 1,429,147,150 lb. for the first 11 months of 1912 and indicate that the production of marketable copper by the regular refining plants from all sources, domestic and foreign, will amount to about 1,560,000,000 lb. for 1912, against 1,433,875,026 lb. in 1911.

According to the Bureau of Statistics imports of pigs, bars, ingots, plates, and old copper for the first 11 months amounted to 276,508,505 lb., and the copper content of ore, matte, and regulus imported amounted to 94,486,041 lb. If the imports for December were equal to the average monthly imports for the first 11 months the amount of copper entering the United States for the year was about 404,721,323 lb., against 334,607,538 lb. for 1911. Considerable of the copper imported had been exported as ore.

The average quoted price of electrolytic copper for the year showed a marked increase over that for 1911. The average for 1912 was about 16c. per lb., as compared with 12.5c. per lb. for 1911. The year opened with copper at 14c. per lb., but since June the monthly average has not been below 17 cents.

There will be no new large producing mines added during 1913. Several of those that began production in 1911 and 1912 will, however, turn out larger quantities than in 1912. At the prices for copper prevailing during the latter part of 1912 the industry is highly profitable, and if the output can be marketed and the price maintained the producers will be in a position to make a still further large increase in 1913.

PIG IRON made in Canada during 1911 amounted to 917,535 tons from 97,732 tons of Canadian iron ore, and 1,628,368 tons of imported ore. Of steel rails, 399,760 tons was manufactured, and 543,933 tons of Canadian coke used.

Book Reviews

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

GOLD MINE ACCOUNTS AND COSTING. By G. W. Tait. 85 pp.; chart. Isaac Pitman & Sons, London, England, 1912. For sale by the *Mining and Scientific Press.* Price $2.

There are many forms of mine bookkeeping, and this volume presents the method of accounting as applied to gold mines in South Africa, where the calculation of costs has at times seemed supreme to other important departments. The material in the book originally appeared as a series of articles in the *South African Mining Journal.* It is a valuable discussion of English methods, but these differ so greatly from American that the American reader is likely to find the book suggestive rather than useful. The absence of any index detracts greatly from its serviceableness.

MINERALOGY OF THE RARER METALS. By Edward Cahen and W. O. Wootton. 211 pp.; index. Charles Griffin & Co., Ltd., London, 1912. For sale by the *Mining and Scientific Press.* Price $2.50.

Greater interest is being taken each year in prospecting for rare minerals and in their technology. The growing use of rare metals and alkaline earths in the manufacture of electric and gas incandescent lamps, production of special steels, and other industries, has created a demand for minerals that are comparatively unfamiliar even to the scientific prospector. It must be remembered that these metals are only used in limited amount, and immediately there is an overproduction prices fall rapidly. Each mineral is discussed under the usual heads of detection, properties, metallurgy, industrial application, annual production, and value, and the little book, which is well bound and of pocket size, will prove very useful.

ENGINEERING AND METALLURGICAL BOOKS, 1907 TO 1911. By R. A. Peddie. 206 pp. D. Van Nostrand Co., New York, 1912. For sale by the *Mining and Scientific Press.* Price $1.50.

Of the making of books there is no end, and a perusal of this volume will give a good idea of the great number issued during the past five years. New editions of works which have appeared during the quinquennium are also included. The whole field of engineering is covered, and metallurgy as well, but only certain phases of chemical technology and a few books on mining geology. Books are arranged chronologically under a list of subheads. Unfortunately, these are badly chosen and are not sufficiently comprehensive; for example, Thompson's 'Applied Electrochemistry' is not listed under electrometallurgy, and numbers of other omissions might be cited. An incomplete check-list is a blind guide, and the including of those old books as have appeared in new edition during the period, while omitting the others, is likely to be confusing to anyone who attempts to use it as a finding list.

BIBLIOGRAPHY OF THE MINERAL WEALTH AND GEOLOGY OF CHINA. By C. Y. Wang. 63 pp. Chas. Griffin & Co., London, 1912. For sale by the *Mining and Scientific Press.* Price $1.25.

The author of this little volume, who is now provincial geologist of Kuangsi, is well known to many Americans, he having studied both at California and Columbia universities after graduation from the Pei Yang University. His earlier volume, 'Metallurgy of Antimony,' reflected great credit upon its author, and it is greatly to be deplored that it has been followed by a volume which is likely to have the reverse effect. The preparation of a bibliography is an ungrateful task, for the amount of work required to make it anything like complete is enormous, and an item which occupies two lines may require two weeks of effort for authentication. China presents even greater difficulties than other topics, for the literature is scattered through obscure and often inaccessible publications. The preparation of such a general bibliography of China as that of Cordier is therefore almost a life work; one prepared with less care is almost valueless. The inconvenient form of this one is doubtless to be laid at the door of the publishers, since the system of dividing a work into sections and omitting an index is characteristically European. The reader is, for example, scarcely able to perceive from the volume that one of the most important papers on gold and silver in North China is that by H. C. Hoover, since it is omitted in the section on gold and silver and placed under 'Metals in General.' But the compiler is also at fault, making remarkable blunders. Thus N. F. Drake's important paper on the coalfields near Tze-chou, Shansi, is given as 'anonymous', though references to abstracts of the same paper appear elsewhere under Drake's name. In other cases references are given to abstracts, but none to the original paper. Many of the most important papers, such as those by Lorenz, Garnier, and Coldre, are entirely omitted. Most of the work on the book was evidently done previous to 1905, since only a few of the recent papers are mentioned. In the introduction the author admits the incomplete state of his work, and it is too bad that the aid of skilled assistants was not invoked, for a half-done bibliography is of little more value than a half-baked cake. Mr. Wang's many friends will regret that his second volume does not maintain the standard set by the first.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

SPEED at which rock can be drilled does not indicate how it will break, as it often happens that rock easily drilled is hard to blast.

SODIUM NITRATE imports for consumption in manufacture of fertilizers and other chemical products amounted in value in 1911 to $16,814,268.

SULPHUR production in the United States in 1911 totaled 265,664 long tons, valued at $4,787,049. Pyrite production was 301,458 tons, worth $1,164,871.

LITHIUM minerals were not produced in the United States in 1911; neither was there any production of potash salts, imports of which were valued at $9,892,324.

CANNEL COAL was mined to the extent of 170,010 tons in 1911, according to the U. S. Geological Survey, Kentucky producing 90,275 and Pennsylvania about 40,000 tons.

SULPHURIC ACID amounting to 438,300 short tons of 60°B., and valued at $2,733,696, was produced from the fume of copper and zinc smelters in the United States in 1911.

GRAVEL used in concrete work should be washed. This costs little more, and insures the absolute dependability of the concrete. Unwashed and untested gravel is a doubtful material to employ.

WATER from streams in California in its progress from the mountains to the sea, a distance of about 100 miles, has been diverted for power, irrigation, and municipal water-supply as many as eight times.

MANGANESE mining has never been a very important industry in the United States, owing to the small extent and the irregularity of the deposits. It is obtained commercially from manganese ores, manganese iron, and silver ores, and manganiferous residuum from zinc roasting.

ACETIC ACID used in Government laboratories for certain analyses must pass the following test: 10 c.c. of acid mixed with 10 c.c. of H_2SO_4, and 2 mg. of $K_2Cr_2O_7$, must not show a green color after standing half an hour, and must have a strength of 99.9%. This test indicates the absence of empyreuma.

COAL-MINING requires, according to investigations by the American Mining Congress, an average investment of $1.41 for every ton of coal mined per year, so that a mine producing 300 to 400 tons per day, or say 100,000 tons per year, requires, on the average, an investment of $150,000. Large plants sometimes involve investments of several million dollars.

SALES of private coal lands in the United States during the past year, omitting sales in Pennsylvania and others of a speculative character, involved 102,464 acres, which realized $18,813,179, an average of $180 per acre. During the past five years, public coal lands covering 133,948 acres were sold at an average price of $18.30 per acre, or about one-tenth that received from private lands, which in some cases brought from $400 to $800 per acre.

THE use of clearance water, to keep the glands free from grit, is essential in all pumps of the plunger or centrifugal type which handle sand or slime. The pressure of the clearance water should exceed the maximum pressure under which the pump delivers; and the water from the gland service should be admitted by the operation of an arrangement which connects the belt clutch with a valve on the water service, so that the clearance water is necessarily admitted as soon as the pump is in action; and automatically turned off as soon as the pump is stopped.

PERFORMANCE of annual labor required upon mining claims can be proved in the same way as any other overt act. In some jurisdictions the filing of an affidavit within a given time is *prima facie* evidence of the performance of labor, and in some jurisdictions the failure to record is evidence that the work has not been done. In any case, it may be proved by other evidence that work has or has not been done. The California act of 1891 providing that failure to file an affidavit of labor rendered the claim open to re-location was held unconstitutional in Harris *v.* Kellogg, 117 California, 490, and was repealed in the act of 1909 which enacted section 1426 of the Civil Code, which provides that the filing of an affidavit is *prima facie* evidence which may be controverted by other evidence.

ELECTAIC incandescent lamps are used in a large number of mines. When properly installed they offer ordinarily only a small fire risk. The presence of explosive mixtures of gases, however, increases this risk. When a lamp bulb is broken in an explosive mixture of gas, this mixture is brought into violent contact with a wire having a temperature of 1800 to 2000°C., or two to three times the ignition temperature of methane. The Bureau of Mines made a number of practical tests, and 1219 lamps, made by eight manufacturers, were used, on natural gas from the Pittsburg city mains, which contains 82% of methane, 16.4% of ethane, 1.5% of nitrogen, and a trace of CO_2. The most explosive mixture of this natural gas and air contains 8.6% of gas. Out of the tests made under various conditions of voltage, and breakage, there were 96 ignitions of gas, the percentage being 100 in many cases.

STEEL BELTS have been used in some of the large manufacturing establishments of Huddersfield, England, during the past year and have been most satisfactory. At a local mill a steel belt 7⅞ in. wide, weighing 119 lb., performs the work formerly done by a leather belt 22 in. wide, weighing 814 lb., transmitting 300 hp. In another mill a steel belt 3½ in. wide, weighing 12 lb., does work in driving 40 hp. that formerly required a leather belt 12 in. wide, weighing 64 lb. These are concrete instances of the success of this German invention. It is especially appreciated for use in the woolen industry, where steadiness and uniform speed are essential to the best results. The steel belt is also an economizer of space, does not slip or stretch, and gives the greatest efficiency of power delivery. A Government test has shown a saving of 61 hp. on a drive of 640 hp. in using the steel belt. Serviceable wood pulleys need not be discarded in changing to the metal belts, for the former can easily and cheaply be adapted for steel belts by stretching a steel band over the top of the grooves, thus obtaining a flat pulley.

DRESSING of zinc-boxes should be timed by the appearance of the first compartment, and should not entirely depend on the question of the efficiency of precipitation. The maximum action of the solution of the zinc occurs at first contact, and it is therefore essential that there be no channeling in the first compartment. As soon as this is noticeable the box should be dressed. The moving and rearrangement of the zinc frees it from much of the adhering gold or silver slime; and the repacking of the box so that the solution comes into first contact with the shortest zinc, ensures the handling of the minimum amount of base metal for the maximum amount of bullion when cleaning up. The use of long zinc-boxes and the exposure of an abnormal amount of zinc, which permits the breaking up of some of the zinc in each compartment, is, however, a method often adopted. In this case the boxes may be left for a considerable time without attention, but the gold is ultimately found distributed over a large area of filament zinc, and is not concentrated on the 'shorts' in the first compartment, as it is when sufficient attention is paid to dressing.

Commercial Paragraphs

THE HENDRYX CYANIDE MACHINERY Co. reports the sale through its English agents, Head-Wrightson & Co., of five 18-ft. agitators. These machines are for South Africa. Another sale through the same agents is announced of two 13-ft. agitators for Siberia.

THE BRITANNIA MINING & SMELTING Co., of Britannia Beach, British Columbia, has placed orders for five 8-ft. Hardinge conical mills of latest design, and one 6-ft. Hardinge conical ball mill, which are to be used in connection with the Minerals Separation, Ltd., flotation process.

The H. W. JOHNS-MANVILLE Co. announces the appointment of C. S. Berry as manager of its Atlanta, Georgia, office, at 31½ South Broad street. To facilitate delivery in the South a stock of roofing, packing, pipe covering, and other J-M asbestos, magnesia, and electrical products is carried at this address. This office also employs a force of workmen experienced in the application of J-M products.

THE JOSEPH DIXON CRUCIBLE Co., of Jersey City, makes the announcement that the selling price of its silicagraphite 'One Quality Only' paint is reduced. This reduction is made because the decrease in the price of linseed oil, which is used as the vehicle, makes it possible, and because it is the aim of the company at all times to give its customers any benefit possible in reduction of price of materials.

Roy D. Hunter has resigned as general sales manager of the SULLIVAN MACHINERY Co. Howard T. Walsh, who has been the European agent of the company, with headquarters in London, is appointed general sales manager, with headquarters in Chicago. Austin Y. Hoy, representative of the company in Spokane, Washington, succeeds Mr. Walsh in London. Louis R. Chadwick, of the St. Louis office, succeeds Mr. Hoy as local manager in Spokane.

It is reported that new equipment to the amount of $700,000 is to be provided for the Hidden Creek property of the Granby Consolidated Mining, Smelting & Power Co. The furnaces, converters, sampling machinery, ore crushers, and settlers are to be installed by the Traylor Engineering & Manufacturing Co. The Pelton Water Wheel Co. is to furnish a water-wheel. The compressor plant is furnished by the Nordberg people, while the Westinghouse Electric Co. is to furnish two 43-ton, six 12-ton, and eight 6-ton electric locomotives and twenty-five 25-ton steel ore cars.

William B. Dickson was elected president of the INTERNATIONAL STEAM PUMP Co., November 19, 1912. He succeeds the late Benjamin Guggenheim, who went down on the *Titanic*. Mr. Dickson has been connected with the steel industry for some time. After several years passed at manual labor in the mills he was transferred to the office, acting at first in a clerical capacity and subsequently receiving rapid promotion through various grades up to that of assistant to the president and managing director of the Carnegie Steel Co. He became a junior partner in the Carnegie Steel Co., Ltd., in 1899. On the formation of the United States Steel Corporation in 1901 he accompanied C. M. Schwab to New York as assistant to the president of the United States Steel Corporation, and later was elected a vice-president of that corporation, which position he held until May 1, 1911.

Charles E. Rogers, general manager for FRASER & CHALMERS, LTD., at Johannesburg, South Africa, who has been in this country several weeks and will return early this month, in speaking of South African development called attention to the fact that copper is found in large quantities in that section of the world. He mentioned in particular the Cape Copper Co. on the south coast, which has a large output, and the Messina Copper Co. on the Transvaal, both of which are backed by British capital. The last mentioned company is comparatively new and is just about to be reached by rails. Copper, Mr. Rogers said, is also found in what is known as the Katanga concession in the Congo, which is Belgian territory. These Congo deposits are believed to be enormous, but production is hampered because of the mineral being found in the form of carbonate, and fluxes are not easily obtainable, and only a small plant is in operation. Mr. Rogers pointed out that zinc properties are being developed at Zeerust, the Transvaal, and that the outlook there is promising. A little tin is found in the Transvaal and prospectors are continually looking for more. Mr. Rogers, who is an American graduate of Cornell University, handles mining machinery and represents several firms. American manufacturers send to South Africa over 60% of the drilling and cutting apparatus used there.

The annual convention of the MEESE & GOTTFRIED Co. was held at the home office in San Francisco December 30-31-1912. There were present besides the officers, the branch managers, salesmen, engineers, and department heads from Seattle, Portland, Spokane, Los Angeles, and San Francisco. Constant Meese, president, made the opening address on December 30, and F. Gottfried, secretary and treasurer, opened the second session on December 31. Many letters were discussed and important papers read, the following being of especial interest: 'Speed Reducers,' W. C. Constant, manager, San Francisco; 'Silent Chain Drives,' H. T. Hesselmeyer, chief engineer; 'Washing and Screening Plants,' F. J. Bodinson, sales engineer; 'The Factory,' W. A. Goeliner, superintendent; 'The Draughting Room,' G. E. Taylor, chief draughtsman; 'Screw Conveyors,' W. C. Conant, manager, San Francisco; 'Rope Drives,' H. T. Hesselmeyer, chief engineer; 'Elevating and Conveying Machinery,' J. F. Bodinson, sales engineer; 'Purchasing for a Manufacturing Plant,' Dave Young, purchasing agent; 'Advertising,' J. A. Bried, advertising manager; 'Salesmanship and Marketing of Our Products,' M. A. Zan, general sales manager. The annual dinner was held at the Commercial Club. The genial sales manager, Mano A. Zan, contributed greatly to the jollity of the occasion by forcing extemporaneous speeches on many who would rather have spent a month at their chosen work. At the conclusion of the dinner, H. T. Hesselmeyer, chief engineer, in behalf of his co-workers and as a slight mark of their esteem, presented handsomely engraved solid gold pocket-knives to both Constant Meese and Fritz Gottfried, the founders of the institution.

Catalogues Received

AMERICAN WELL WORKS, Aurora, Illinois. Bulletin No. 127, 'Economical Irrigation by Pumping.' 72 pages. Illustrated. 8 by 10 inches.

DEANE STEAM PUMP Co., 115 Broadway, New York. Bulletin D-225, 'Triple Plunger Artesian Well Pumps.' 16 pages. Illustrated. 6 by 9 inches.

JEFFREY MFG. Co., Columbus, Ohio. Bulletin No. 46. 'Jeffrey Swing Hammer Pulverizer for Laboratory Use.' 4 pages. Illustrated. 6 by 9 inches.

POWER & MINING MACHINERY Co., Cudahy, Wisconsin. Spanish catalog on mining and smelting machinery, etc. 112 pages. Illustrated. 6 by 9 inches.

EDGAR ALLEN AM. MANGANESE STEEL Co., McCormick building, Chicago. Bulletin No. 54, 'Renewable Point Dipper Teeth.' 12 pages. Illustrated. 6 by 9 inches.

THE HAYWARD COMPANY, 50 Church street, New York. Catalog No. 40, 'Orange Peel, Clam Shell, Drag Scraper Buckets, and Other Digging Machinery.' 94 pages. Illustrated. 9 by 12 inches.

CHICAGO PNEUMATIC TOOL Co., Fisher building, Chicago. Bulletins No. E-22. 'Heavy Duty Electric Drills for Alternating Current.' E-26. 'Universal Electric Drills Operating on Direct or Alternating Current,' E-27, 'Heavy Duty Electric Drills.' 34-G, 'Receivers.' All illustrated. 6 by 9 inches.

NATURAL GAS produced in Ohio in 1911 amounted to 49,449,749,000 cu. ft., valued at $9,367,347, and obtained from 450 wells. The consumption was 112,123,029,000 cu. ft., valued at $22,792,270. The difference between production and consumption represents the quantity piped from West Virginia and Pennsylvania.

TABLE OF CONTENTS

EDITORIAL

NO country subscriber has yet taken advantage of the much advertised opportunities afforded by the parcel post to send this editor a basket of fruit or a chicken—we just mention the matter.

SPOKANE is preparing for the second annual meeting of the Northwest Mining Congress, to be held February 19, 20, and 21. Visitors may be sure of a hearty welcome and an excellent time.

COPPER production at the Braden mine in December amounted to 910,000 pounds and the property has become the most important producer in Chile, one of the notable copper-producing countries of the world.

HORTICULTURE as an adjunct to gold mining is one of the signs of the times. The Natomas Consolidated has just established a large nursery, which is a reminder that this dredging company is as busy reclaiming as destroying land.

INCREASE in ship-building in the United States during the past year was remarkable, the tonnage built in the last six months of 1912 being 43 per cent larger than in the same period of 1911. Evidently the influence of the Panama canal is already being manifested.

GRANT by the Federal Government of permission to the Great Falls Power Company to extend its transmission lines over public lands clears the way for the electrification of parts of the main line of the Chicago, Milwaukee & Puget Sound railway and is an important move in the development of the natural resources of Montana that is a direct outgrowth from the development of copper mining in that state.

"WE lead, others follow," was once proudly announced by one of our contemporaries which has since adopted the 'By the Way' department first established in the *Mining and Scientific Press*, our convenient two-column measure and large faced type, and now plans to send its editors into the field and 'squirt some human interest into' its editorials. Apparently the policy of the *Press* commends itself to rivals as well as readers.

DIAMOND-DRILLING from the deep levels of the Goldfield Consolidated mine is to be done. The core-drill has been of great service in discovery of other minerals, and while in gold mines the irregularities of deposition prevent the drill being used to find ore, there is no reason why it should not be of great service in the preliminary task of finding

the veins, determining the formation, and working out the geological structure.

WASHINGTON and Idaho are among the states in which efforts are being made this winter to secure appropriations for geological surveys. Both states have large resources that wait development and both can well afford to spend the small sum necessary to secure expert aid in problems relating to mineral production.

ROCHESTER is the district of the hour in Nevada. It lies at the head of Rochester canyon, on the flanks of Crown Point, or Nenzel, as the newcomers are calling one of the peaks in the Humboldt range. The district is reached from Lovelocks and Oreana on the main line of the Southern Pacific. At present most of the traffic is by way of Lovelocks, from which point the journey may be made by automobile, though over a poor road leading first 18 miles up the valley parallel to the railroad, and thence up the canyon to the new town. The latter has telephones, boarding houses, assay offices, saloons, and all the usual hodge-podge of a new mining district. It also has at least one good property and abundant prospects of more. It is receiving the serious attention of experienced engineers and investors. The deposit which attracted attention to the district outcrops boldly at the head of the canyon. From this outcrop Mr. J. F. Nenzel shipped two carloads of ore early in December, that was said to be worth nearly $100 per ton, mainly in silver. The lode has been known to a few men for nearly a dozen years and has been repeatedly located and the claims allowed to lapse. Secrecy was maintained in part to avoid litigation growing out of conflicting claims and work was only begun in earnest when it was thought that these had been successfully harmonized. How important and how extensive the discovery may prove remains to be seen, but prospects now are excellent.

ADOPTION of small drills, which can be handled by one man, for mining in the Calumet & Hecla properties is being imitated by the other companies in the Lake Superior district and it is prophesied that within a short time their use will there be almost universal. Eastern market journals acclaim the change as "revolutionizing ground breaking," quite oblivious to the fact that a similar revolution has been in progress in Western mining districts for many years, without producing any startling upheavals. Whether large or small drills give better results depends largely on the use to which they are to be put. That small drills cannot do as much work as large in shaft-sinking or tunnel-driving, for example, is as evident as that small drills are better than large for stoping, especially in narrow veins. Striking the best balance between mechanical horsepower and human energy required is a problem of management. Where it is desirable to use a rather light drill it is obviously better to make it light enough for one man to handle, rather than employ two men for work which is but little beyond the power of one. It will be remembered that the long strike at Reefton, in New Zealand, was the result of the refusal of the miners' union to allow a single man to handle a drill, but the demand of the men was so obviously unreasonable that they were unable to enforce it. Considerable economy in mining costs has resulted from the use of the 'one-man' drill elsewhere, and there is every reason to believe that equally good results will accrue in the copper mines of Lake Superior.

California's State Mining Bureau

The State Board of Control, an excellent feature of the financial administration of California recently established, has been pointing out places where better methods would lead to more economical transaction of the business of the state. The efforts of the Board deserve the support of all good citizens, and it is a pity that other states do not maintain similar central business committees. It is in part because we do approve so heartily of the general purpose and work of the Board, that we regret to see that it has been led into making unfair criticisms of the State Mining Bureau. That the latter is not accomplishing all that it should for the benefit of the state is frankly recognized by its best friends, and by no one more frankly than Mr. W. H. Storms, the present State Mineralogist. In a recent editorial we pointed out that the state was keeping up an expensive establishment without making adequate use of the organization. The heavy overhead expense that must be met in some form is being paid; but no active study of the state's resources is being made, nor has any been attempted for some years. It avails little to pay the salary of a mineralogist or geologist, if no allowance be made for field expenses; and that is the situation in California. The museum, the library, the determinative laboratory, all these are good and all are necessary. Possibly the present expense of maintaining them is a trifle high, but, if so, no adequate analysis of the figures to prove it has been published. It is to be remembered that the money paid by the Bureau for rent goes back to another state department, and if the janitor and the stenographer receive a few dollars more per month than in a commercial office, the same is true of practically all minor state employees.

It is a well recognized rule that in government service less important positions are over-paid and high-grade men receive smaller salaries than those paid in private employment. Granting that there is room for a trifle of economy in the work now being conducted, no one can fairly maintain that any such amount could be saved from the present appropriation as would be needed if the Bureau took up the serious field studies that the times demand. The place to study the geology and resources of the state is in the field, and if the Bureau has any public function to serve at all, it would seem to be in promoting the economical development of the state's mineral resources. Mr. Storms has been given no money with which to do this work, and it is unfair to blame him for the lack of results. Such money as remained unexpended when he was appointed was needed to complete work undertaken by his prede-

cessor, and to realize as much as possible from expenditures, perhaps not well advised, but already made or contracted. The fact that the Board of Control criticises the making of trips to the mines, and evidently regards such studies as private work, shows a total lack of comprehension of the real field of usefulness of the Bureau. For the information of those who do not know, we may state that since Mr. Storms went into the office he has made no examinations for fees. He has taken the only proper attitude for a state officer, that if the examination was of public use he should make it for nothing, and if not, he should not make it at all.

As to the charges of financial irregularities, the answer is simple; it is merely a matter of bookkeeping. Those who have never worked for an American state or for the United States, may be interested to know that employees when on official journeys must usually advance their own money and await reimbursement at the later convenience of auditing officers. This often becomes a serious burden, for red tape is abundant and long, and auditors' hours are often shorter than are those of field assistants. We have known young men employed by the United States Geological Survey and earning less than $100 per month, who had several months' salary tied up in expense accounts. We have also known whole parties to be held at hotels on expense because money for traveling had not been advanced and personal funds were exhausted. Under these conditions a state officer who finds a petty cash account that can be used as a revolving fund, guards it zealously and considers himself fortunate. It happens that the California State Mining Bureau has such a fund, originating through gifts, and that the trustees, acting on the advice of counsel, refused to turn this into the general state treasury when demand was made by the Board of Control. Whether they were right in this is a nice legal question. In the meantime it has long been customary to advance from this fund money for traveling and other expenses requiring immediate cash outlay, and to accept a due bill from the employee receiving the money. Later the amount was refunded when the bills had been finally audited and state warrant issued. Since freight, express, and telephone bills for small amounts came in regularly, there was a standing due bill in favor of one clerk, to the amount of $50. This is the small basis of the big mountain of condemnation. In all the years no money was ever lost, and upon objection by the Board of Control the practice itself stopped several months ago. To state the case in such terms as to make it appear that employees of the department had been 'grafting,' is entirely unfair.

We have frequently criticised the State Mining Bureau. We have been frank in stating our belief that under Mr. Storms' predecessor the institution was of small benefit to the state. With the appointment of Mr. Storms to the position we had hopes that a better day had come. He is an honest able official who has greatly improved the work of the Bureau and has made the best of a bad situation. The organization, however, is wrong and the funds are inadequate. It will be remembered that in 1908 Messrs. F. W. Bradley, Curtis H. Lindley, and E. A. Stent, finding in a critical case that the trustees of the Bureau had no real control of its affairs, emphasized their disapproval by resigning. It is certainly an anomalous condition to have trustees and then leave appointments to a Governor at the same time that a Board of Control, acting for the state in general matters, presumes to decide whether or not individual field trips made by the State Mineralogist are proper. A fundamental change in the organization is necessary if efficient work is to be done. A free hand is needed if good work is to be accomplished even by the best appointee. In the meantime we urge candor and fairness in discussion of the situation.

New Copper Production

Taken as a whole, the conditions at the close of the year, as shown by the report of the Copper Producers' Association, make the amount of new copper to come from the developments under way a more serious question for the coming twelve months than it has been during the past year. The Miami Copper Company is now producing at the rate of approximately 3,000,000 pounds per month; Greene-Cananea is producing more than 4,500,000 pounds; the Braden, which has only been in operation about one year, produced during 1912 something over 9,000,000 pounds, and is expected to yield something more than 40,000,000 during the coming twelve months; the Anaconda output for 1912 totaled, in round numbers, 294,700,000 pounds, as compared with 260,600,000 pounds for 1911 and 267,872,000 pounds for 1910, and so long as the present copper market holds may reasonably be expected to show further increases; the Guggenheim and affiliated properties, including Utah Copper, Nevada Consolidated, Ray Consolidated, and Chino, showed an increase in 1912 over the previous year's figures of 68,000,000 pounds, of which the greater part came from the two last named. Students of the situation anticipate that Ray Consolidated and Chino will probably more than double their present rate of output during the year to come. There are several important properties of less magnitude that must be taken into consideration in estimating the volume of new copper seeking a market in the near future. Among these may be mentioned the Hidden Creek mine, which is being rapidly equipped by the Granby, the Giroux, now making regular shipments to Steptoe, the Shattuck-Arizona, now sending its ore to the Calumet & Arizona smelter, and several Butte producers that are rapidly growing in importance. The Tuolumne has just opened a body of ore on the 2000-foot level: the Pilot Butte, which is a neighbor of the Tuolumne, is now in ore, and, taken as a whole, the Butte district is now prepared to play as large a part in the country's copper production as at any time in the past. It is easy to see that notwithstanding the enormous financial strength that is supporting the present copper metal market, the men in control will have their work cut out for them during the next twelve months unless recourse be again had to a policy of curtailment.

Lead Plant of the International Smelter

By L. S. Austin

The plant of the International Smelting & Refining Co., situated at the mouth of Pine canyon, four miles from Tooele, Utah, was originally built for treating the copper-bearing sulphide ore of the Highland Boy mine of the Utah Consolidated Mining Co. The smelter was arranged for five reverberatory furnaces of 200 to 250 tons' capacity each. It was intended that the supply from the mine should be supplemented by copper ores from other sources. The amount of Highland Boy ore fell off however, and it was felt that to operate the plant profitably, the tonnage should be increased by smelting silver-lead ores. The smoke from the plant is carried up the canyon, but this advantage is in part offset by the necessity of transporting custom ores up a grade with 500-ft. rise from Tooele Junction on the main line of the San Pedro, Los Angeles

& Salt Lake railroad, 7 miles distant; this branch being a subsidiary enterprise of the company.

For the new lead-smelting department there was available the already existing trackage, receiving-bins, sampling-mill, crushing machinery, and a power plant, which obtained its steam supply from the waste-heat boilers of the reverberatories.

It was planned to crush the lead-bearing ores and to mix them with flue-dust and sinter. This product was to be smelted in the blast-furnace, with the addition of some silicious ore and fluxes. The flue-dust, both from the blast-furnaces and from the sinter plant, was to be caught in flues and in a bag-house, the slag was to be wasted, the matte was to be treated in a converter (using the existing equipment and catching the converter fume in another bag-house), while the base bullion was to be remelted, skimmed, and molded into bars for shipment to the refinery of the company at East Chicago, Indiana.

The transportation of ores and supplies at and within the plant is in the main effected by steam or electric locomotives and a terraced site is consequently satisfactory. The ores are dropped or shoveled from the railroad cars into the receiving bins, and as fast as sampled and crushed, sent by belt-conveyors to the feed-bins. There is little shoveling done except from cars which are not self-discharging. Before the beginning of lead-smelting, however, a large stock of ore was accumulated and this had to be put in stock-piles adjoining the yard-tracks. This ore had to be expensively handled and when sent to the furnace had to be picked up with the aid of a track-derrick and grab-bucket.

The ore, fluxes, and fuel coming in railroad cars

from the main line, arrive over the scales at the highest level, and after weighing are sorted upon any one of the six storage tracks. When they are discharged the materials are placed as follows: (1) The coke is dropped into one of the feed bins or is unloaded on a stock pile; (2) the coal goes to one of the western receiving-bins; (3) the ore and limestone go to the eastern row of receiving-bins. The building for the receiving-bins, 30 by 296 ft., contains a double row of sloping-bottom bins marked from 'A' to 'N,' and of different capacities. These have chutes at 10-ft. intervals, 28 to each row. The building extends north and south, while west of it, 30 ft. away, is the four-story sampling mill, in area 30 by 34 ft. Imagine a transverse plane at the middle of the bin-building; it will divide both mill and bins into duplicate sections, north and south, each taking from 14 chutes of the eastern row of storage bins. At the centre of the bin-building are four additional bins having hopper bottoms. The western row of receiving bins is devoted to supplying the copper department of the works, while the eastern row and the four centre bins receive ore and fluxes for the lead-smelting. Considering now either section devoted to lead-smelting; ore from any of the 14 chutes can be withdrawn upon an endless-apron feeder capable of being set by any desired chute. From the feeder the ore falls upon a 20-in. conveying-belt, which delivers it upon a transverse 20-in. conveying-belt taking it to the shaking-feeders of the first Blake ore-breaker in the mill. Beneath the four central bins is another troughed conveying-belt, which may be run in either direction and so may deliver upon the 20-in. transverse belt of either section as desired. The transverse belts are 25 ft. centre to centre.

At the mill, the transverse belt, as already stated, delivers to the perforated shaking-feeder where the fine ore is removed, the coarse going to the first crusher, set with a jaw-opening of two to three inches. The combined crusher product and the fine material are unitedly elevated to the top or fourth floor of the mill. The elevator discharge descends upon four Brunton samplers in sucession, one-fifth of the ore-stream being cut out each time or 1-625th in all, being 3.2 lb. per ton. The successive fifths as fast as they are cut out go through a crusher or through rolls before the next following cut is made. The rejected portions (or principal) drop into the boot of elevator No. 2 to be delivered to the crushing system of machines and trommels where all is crushed to pass a revolving trommel having 5/8-in. round holes. The crushed product is finally delivered upon a transverse 20-in. conveying-belt which drops it at the west side of the mill upon longitudinal 20-in. conveying-belts, these latter leading in three sections in series to the north end of the feeding-bin building, that building being 350 ft. directly north and in line with the receiving-bin building. The continuation of the high-line track through the latter building is carried through the feed-bin building. This building 30 by 250 ft. has 26 hopper-bins, which receive crushed ore not only from the movable tripper of the 20-in. conveying-belt, but from cars on the track alongside and parallel to it. The south feed bins are reserved for the crushed ore intended for the sinter plant; the north bins receive sintered ore, limestone, iron ore, and silicious ore intended for the blast-furnaces. Coke is stored in the north-end bins, but when the supply in them runs short, it is taken from the stock-piles.

At a distance of 125 ft. west of the south end of the feed bins is the sintering plant or building, 64 by 42 ft., which contains four 100-ton capacity Dwight-Lloyd sintering machines with grates 42 in. wide. The building is being extended northward to contain six additional machines. At the south end of the feed-bin building is a pit beneath the charge-track to contain the lower or feed-end of a belt-conveyor of an inclination of 18 degrees which leads to the fifth floor of the sinter-building.

Referring again to the feed-bins; each one may be regarded as in two, the upper or main bin capable of holding four carloads, while below it is suspended the weighing hopper equipped with Fairbanks scales which may hold a ton. From the bin, ore is withdrawn into the weighing hopper. Beneath the weighing hopper runs the charge-car track. There are two motor-propelled blast-furnace charge-cars and one sinter-furnace charge-car. Ore and coke having been drawn off into the several weighing hoppers, the charge-car is run under them successively and receives first the coke then the various items of the charge. As the material is dropped from the hopper the car is slowly and skillfully moved beneath the falling stream, so that it is distributed in the car to suit the running of the furnace. Thus it may be largely distributed at the ends, evenly throughout, or more to the centre of the car. The car is approximately as long as the furnace. When charged it is run to the furnace. To charge the furnace the car is run over it, the hinged shutters at the top of the furnace are opened, the bottom doors of the charge-car open and the charge drops a distance of nearly 12 ft. into the furnace. As the result of experience for a sinter charge the smelting column is carried at 10 to 12 feet.

The blast-furnace building, 30 by 75 ft., is on a side-hill site, and is 90 ft. north of the feed-bin building, its feed-floor being at the feed-track level The crucible floor of the furnace is 5 ft. above the slag-dump level. In this way the fore-hearth set upon the slag floor has plenty of height beneath the slag spout of the furnace. The distance from the crucible floor to the feed floor of the furnace is 30 ft. The building contains two furnaces 45 by 180 in. at the tuyere level and set 30 ft. centre to centre, set transversely to the building, so that there is a separate feed-floor track to each furnace. There are three wrought-steel jackets per side, each having four tuyeres or 24 to the furnace. The fore-hearth is 10 by 5 ft. and 5 ft. high with rounded ends. Each furnace has its own down-take, taken off below the feed floor, and leading to a cylindrical dust-catcher 20 ft. diam. by 20 ft. high. From each dust-catcher a branch 6 ft. diam. connects to the main flue 8 ft. wide by 12 ft. high, this flue having a V-shaped bottom with slides at intervals for the removal of accumulating dust. Provision is also made to withdraw the dust into a tram-car from the bottom of the

dust-catchers. The main flue, 525 ft. long, leads to the bag-house.

Herewith is given a typical blast-furnace charge. It will be seen that of the 4900 lb. of charge (not counting slag) some 70% is sintered material. The charge contains 902 lb. of lead, or 16.7%, from which should be subtracted 40 lb. contained in the slag, 60 lb. in the matte, as well as the flue-dust and volatilization loss; the latter two items being recoverable in the flues and bag-house. This charge makes slag of the composition SiO_2, 31%; FeO and MnO, 35.5%; and CaO, 17.5%. Of the total sulphur, 40 lb., or 1.5%, enters the slag, and 53 lb., or 30% of the whole, is volatilized. This leaves 84 lb. of sulphur, which should result in 380 lb. of matte, being a matte-fall of 7% computed on 5400 lb. of actual charge. Examination of the analyses of the items of the charge will reveal interesting details. A typical matte, specific gravity 4.897, is as follows:

	Per cent.
Pb	15.80
Cu	7.80
Fe	45.00
Zn	6.00
S, As, etc., by difference	26.20

Besides the above typical charge, a novel feature is the introduction, after every third to sixth of these, of a 'crude-ore charge' which contains about 1150 lb. of sinter only (23.5% in place of the usual 70). The object of doing this is to slightly modify the slag-type. This is in accord with observations already made by experienced metallurgists accustomed to the performance of the lead blast-furnace, who have noted that when a change occurred in the charge, it often resulted temporarily in a hotter corrosive slag which tended to remove accretions in the furnace and fore-hearth.

The slag, overflowing from the settler or fore-hearth, is received in conical slag-pots of five tons capacity. These are hauled to the dump by a 12-ton electric locomotive. Settling has been so well performed that both the molten slag and the shells are as a rule rejected. It has been found to be more profitable to smelt the converter slag from the copper-smelting department. A typical analysis of the rejected slag-shells contains: SiO_2, 32.5; FeO, 29; MnO, 6.0; CaO, 15.0; ZnO, 9.0; Al_2O_3, 4.0; S, 2.0; Pb, 1.2%; all by wet determination. The furnaces run rapidly; thus, on November 22, 1912, No. 2 furnace put through, on three shifts, 102 charges of 4900 lb., or 250 tons. The percentage of coke is from 12.5 to 14, or with the slag, from 12 to 13.5% of the charge. The limestone is coarsely crushed at the sampling mill, and is delivered by belt-conveyor to one of the feed-bins.

Crushed ore is weighed to the sinter-charge car, as already described for the furnace-charge cars, and from it is dropped through a hopper upon an endless-belt feeder. This delivers it to the inclined belt-elevator already mentioned. Arriving at the sinter building, it is taken by conveying belt to the hoppers of the sintering machines. The inclined conveying belt is stopped or started to supply the charge as desired. The materials are fed upon the sintering machine over a distributing apron which delivers it to the thickness of 4 in. upon the 42-in. endless slowly-moving grates. This machine is fully described by H. O. Hofman.* The discharge end of the machine is just outside the building, and the product drops from it through a grating into steel hopper-bottom railroad cars. These cars when full are switched around upon the high line and their contents dropped into the feed-bins.

The sinter charge may be quite variable, the sulphur ranging from 12 to 15%. Thus, in August 1912, a sinter charge of 4200 lb. when going to the machines was computed to carry SiO_2, 18 to 20%; Fe, 18; Pb, approximately 20; S, 14 to 16%. This was roasted until there remained 3 to 5% sulphur in the sinter. More recently leady oxidized ore with an iron excess has been added, raising the weight of the charge to 5200 lb., and it was found that the same number of charges could be put through as before, or that the capacity of the machine was increased in that proportion. The table on the following page represents this charge.

From this it is to be seen that as high as 26%

The base bullion is tapped from the lead-well into wheeled pots or bowls that hold 3 cu. ft., and are taken to the drossing plant, where the lead is dumped into one of the two kettles, each of which will hold 33 tons of lead. When full the kettle is skimmed, using a Howard press, the skimmings or drosses being returned to the blast-furnace while the clean base-bullion is siphoned into 100-lb. bars. For sampling the product, there is used a mold with 10 conical depressions, each holding approximately half an assay-ton. In taking the sample from the kettle, the skimmed bullion, at the temperature of 400°C., is agitated from the bottom by stirring-paddles and the sample removed from time to time as the charge is siphoned into the molds. These half assay-ton samples are subsequently assayed without trimming to the exact weight, the assay value being adjusted to the plus or minus error.

The bag-house, of brick, 56 by 111 ft., and lying east and west, is divided into seven bays and has a steel truss roof covered with tight tongued-and-grooved boards with a patent roofing. In each bay are 144 cotton bags 31 ft. long by 18 in. diameter, making a total of 1008 bags in all. The temperature of the entering gases is maintained at 150°F. On the north side of the house is a brick flue, 6 ft. wide by 13 ft. high inside, the top three feet being divided off horizontally to form a top flue. In the top compartment are openings below the thimble-floor 18 in. diam. and in the lower similar openings 36 in. diam. These openings are closed by disk-valves operated outside the flue by their stems. The top flue is the reverse-current flue, which is connected to an independent fan. Generally, the gases are passing into the bag-house by the lower flue, being driven in by a large centrifugal fan run by a 100-hp. motor. The bags of each section are shaken six times daily, the procedure being as follows: The lower valves of the section are closed, the upper ones opened. The bags are thus collapsed and the attached dust loosens and falls into the chamber beneath the thimble-floor. The valves are next changed, expanding the bags. This operation of expanding and collapsing, being repeated three or four times, frees the bags from most of the dust,

The composition of the blast-furnace matte has already been given. This is to be treated in a basic-lined converter belonging to the copper-smelting department of the works, an equipment already available for use. For the recovery of the lead in this matte, which is volatilized in the bessemerizing operation, a bag-house as large as the one just described has been provided. It will thus be seen that there is no roasting of the matte nor of its return to the blast-furnace charge, but the matte, as fast as made, is sent for treatment to the converter. The copper, the product of this operation, is yielded as blister copper available for electrolytic treatment.

Some further description of the illustrations will be of interest. The sinter-charge car is shown in position to drop its contents into a hopper. An endless-belt feeder delivers upon the feed end of the inclined belt-conveyor leading to the sinter mill. The sinter-machine building is five stories high. At the right is the feed-bin building. The inclined belt-conveyor from the south end of the bin building takes the sinter charge to the fifth floor of the sinter building. At the left is seen the sinter machine discharge. This drops into the railroad car below. The horizontal pipe in the foreground carries the fumes from the machines to the lead plant chimney. At the left of the chimney is the feed-bin house; at the right, the bag-house. In front, entering the chimney, is the sinter plant flue. The downtake from the bag-house to the stack is shown.

The illustration of the blast-furnace and accessories shows the slag-car and forehearth. The crucible floor-level is 5 ft. above the slag-floor. Matte is withdrawn at the other side of the forehearth. Base bullion is tapped into the 3-ft. wheeled bowl at the near side of the furnace. In working the lead kettle the follower is raised and the Howard press lowered into the molten lead. The mold is filled with the skimmed drosses. The press is now raised and the follower pushed into it as shown. The molten lead is squeezed out. The press is now moved over and the bottom dropped. The drosses fall out on an inclined surface, ready for removal to the blast-furnace.

Secondary Sulphide Enrichment of Ores—II

By C. F. Tolman, Jr.

Various Types of Enrichment

**Gold Enrichment.*—It is unnecessary to discuss further the enrichment and impoverishment of gold deposits, as W. H. Emmons' paper, already cited, is accessible to American engineers. In addition to the rearrangement of metals that takes place above and at the top of the oxidized zone, by means of ferric and manganese solutions, there has often been noted a moderate increase in the gold and decrease in silver content to considerable distances below water-level. It is not certain whether this is due to an actual enrichment in respect to gold, or is an apparent enrichment due to the decrease in the relative amount of the sulphide minerals.

Silver Enrichment.—Silver undergoes both oxide enrichment and sulphide enrichment, the first often more important on account of the insolubility of the oxidized products. C. R. Keyes[33] has emphasized the fact that the ground-water of the semi-arid regions contains a large amount of chlorine, and the formation of the little soluble haloid compounds is the result. It is known to the prospector that the pocket-like bonanzas of silver ore in the Southwest are generally superficial. (Note the term 'chlorider' is applied to the miner in the Southwest who works any rich ore pockets, especially those close to the surface.) There seems to be another factor of importance to explain the great decrease in grade of silver ore at the water-line in such famous bonanza silver mines as Tombstone, the Commonwealth, and the Jack Rabbit mines, all in Arizona. In all these cases, great flows of underground water were encountered when the attempt to pump the mines was made. It is possible that the veritable 'sea' of underground water so diluted the downward creeping silver-bearing solutions that their silver content went into solution instead of precipitating.

When the descending solutions are acid, and chlorine is not an important constituent, valuable silver sulphide enrichments may develop, especially in connection with copper deposits.

Lead and Zinc Enrichments.—It is difficult to recognize a secondary lead or zinc sulphide by mineralogical criteria, because both primary and secondary sulphides form the same minerals. I have, however, examined specimens of lead ore in which the outer portions of the galena crystal assayed over 100 oz. in silver per ton, while the centre core carried between 5 and 10 oz. Here the silver-bearing galena was a secondary sulphide. Established cases of secondary enrichment[34] have been described, but they will not be considered here, since this paper deals chiefly with the more important and interesting copper enrichment.

Enrichment of Copper Ores.—Copper enrichments fall into three distinct types, which are represented by the three well known ore deposits of Butte[35], Bisbee[36], and Ray[37].

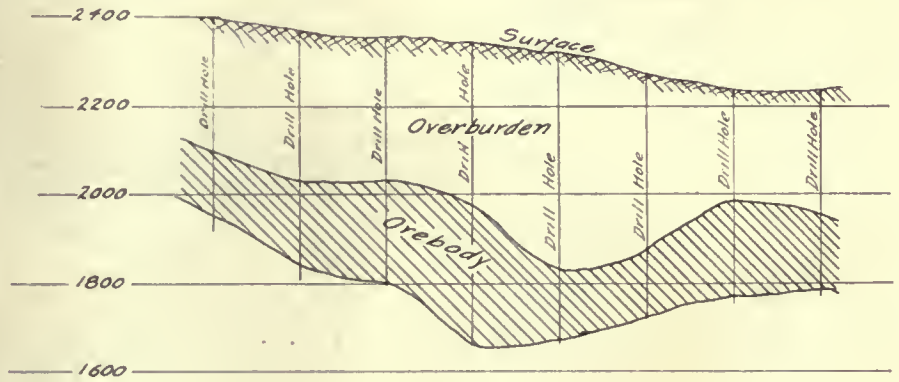

Fig. 3.

In the Butte type, the enrichment is caused by cupreous solutions, strongly acid in composition, descending to great depths along strong lines of fissuring. The granitic country rock does not neutralize the solutions to a marked degree and the secondary alteration is largely a kaolinization of the country rock.

At Bisbee the deposits are in limestone, the descending solutions reacting with the $CaCO_3$ to form carbonates of copper which migrate downward very slowly, the solutions are neutral, or even alkaline (oxidation is artificially accelerated by mine workings, and the solutions are therefore more acid than under conditions actually obtaining when the deposits were formed). And the sulphide enrichment occurs as layers around kernels of low-grade pyritic ore.

In the disseminated type represented by Ray, the solutions diffuse downward throughout the mass of fractured altered rock. The solutions remain acid wherever they are concentrated, but may be neu-

tral or even alkaline (see discussion above), and then may be highly charged with silica. The deposits take the form of a wide-spread sheet at or near the water level. (Fig. 3.)

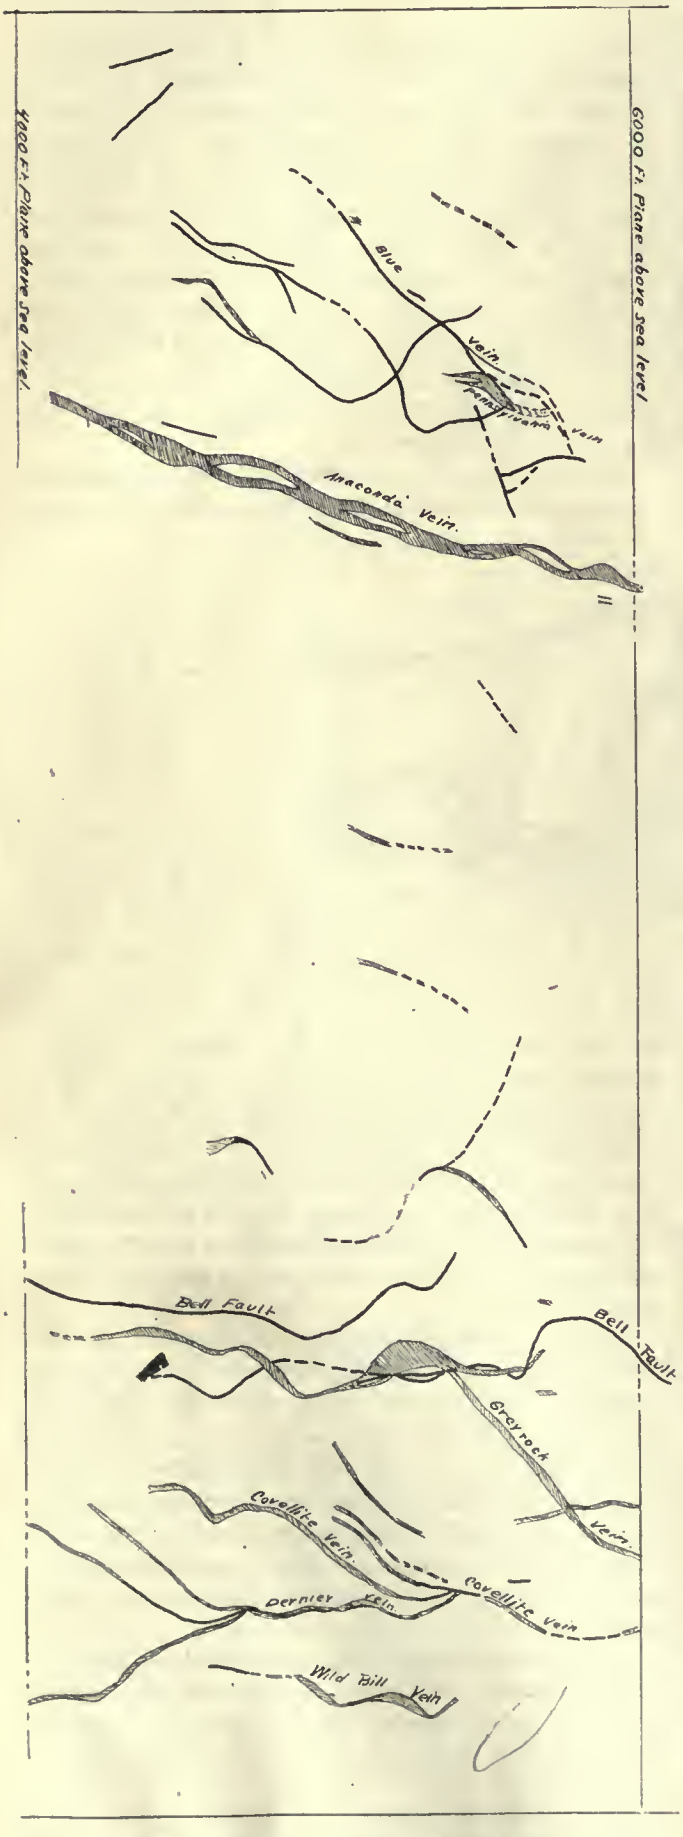

FIG. 4. CROSS-SECTION OF ANACONDA, GREY ROCK, COVELLITE, AND WILD BILL VEINS AT BUTTE.

(The shaded areas represent copper ore; the solid lines, barren fissures and faults.)

Structural Relations Governing Secondary Sulphide Deposition

1. *Strong Faults, Veins, and Reopened Fissures.*—Butte is the classic example of great secondary concentration down fissures (Fig. 4). The earliest ore deposition occurs as massive quartz pyrite veins, which have been broken and rebroken, the earlier periods of breaking being accompanied by renewed ascending metallizing solutions, but with each break secondary enrichment also penetrated from above, and the great bonanzas were formed near the water level, and lower-grade deposits to great depths.

The Old Dominion mine, Globe, Arizona (Fig. 5), is an example where a prominent break (fault) governed both primary and secondary deposition of ore. On the hanging wall of the fault underneath

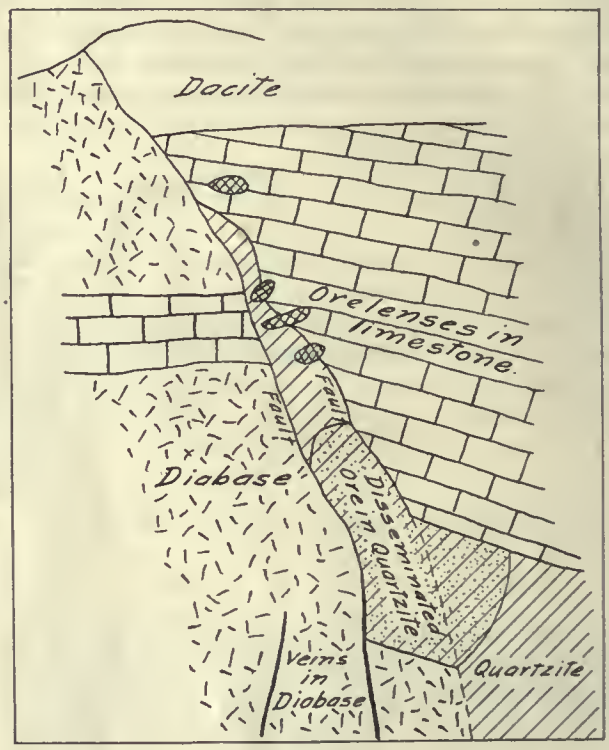

FIG. 5.

the dacite flow is first limestone, then quartzite, and then diabase. In the limestone there are great lenticular masses of iron oxides carrying oxidized copper ore, the value of which have been concentrated by oxide enrichment, but no sulphide enrichment occurs. The brittle quartzite was crushed by the fault movement and enriched disseminated sulphide ores occur in the shattered quartzite, while in the diabase the fissures are well defined and narrow enriched veins of sulphide ore are developed.

Some years ago I observed in the Capote workings at Cananea, Mexico, a curious case where structural features localized oxidation and sulphide deposition without regard to the water-level. (Fig. 6.) Here the well developed hanging wall of a vein allowed a rapid downward oxidizing circulation which developed oxidized ores from the surface down. The solutions working inward toward the foot-wall produced a secondary sulphide enrichment which developed under the oxidized ore.

2. *Ore Blankets Caused by the Leaching of a Permeable Copper-Bearing Formation.*—The great 'por-

phyry coppers' of Utah, Arizona, Nevada, and New Mexico fall under this head. The accidental structural troughs, and the relations of present and past topographies modify the form of the deposit and govern the amount of enrichment, but nevertheless they all have certain features in common:

(*a*) The primary ore in an impregnation of an extensive mass of rock by copper-bearing pyrite. Whether the original ore was a mixture of pyrite and chalcopyrite or was cupriferous pyrite, the result of leaching and concentration has been the same.

(*b*) The entire mass is permeable to descending solutions, and therefore the portion above water-

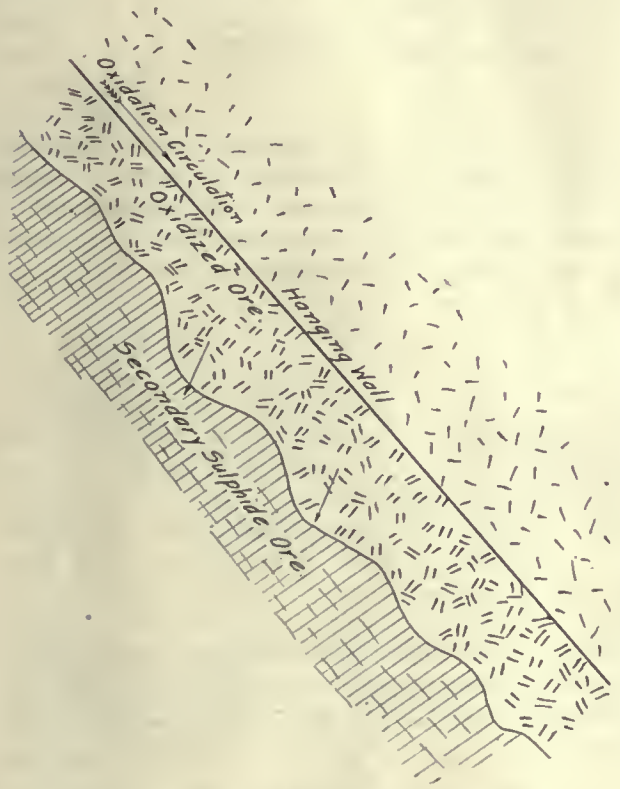

Fig. 6.

level is leached, and the metal is deposited below as an extensive sheet of ore.

(*c*) The rich ore is deposited generally at the top of the orebody, where the chalcocite may completely replace the pyrite. With depth the chalcocite decreases in amount, appearing as shells around the pyrite grains, finally completely disappearing where the primary ore is reached.

Effect of Rock Composition, Topography, Climate, and Structure on the Formation of Disseminated Ore

The composition of the rock will often be an important and at times the controlling factor governing sulphide enrichment. I have met so many instances where dense contact metamorphic ore deposits of closely intergrown garnet, epidote, quartz, pyrite, and chalcopyrite have successfully resisted the attack of oxidizing solutions, that I have come to believe that only under unusual conditions can such orebodies be leached and enriched. On the other hand, a contact deposit of coarse granular garnet readily goes to pieces in the belt of weathering. In addition to the power of resistance of the rock to physical and chemical disintegration, the question as to whether or not the underlying rock contains a precipitating agent may become important. Theoretically a case may be postulated where the descending waters are conducted out of the pyritized zone into a rock which contains no sulphides. Such a case would be more likely to occur where the enrichment has been a long continued process during which there may have been topographic changes and faulting. A number of examples are believed to have occurred in the Globe district, Arizona. When the Miami Copper Co. discovered the remarkable orebody in a schist whose surface is stained with carbonates and silicates of copper and which is now worked, it was to be expected that the still more strongly copper-stained and brecciated schist area of the lower Pinto creek would be tested. Deep drilling, however, showed that carbonates and silicates predominated to the greatest depths reached and the interesting question (especially to those who bought stock in the Cactus Copper Co.) is, why so little chalcocite was deposited from solutions that carried such large amounts of copper. As has already been suggested in the case of the Miami foot-wall, it appears that the brecciated zones down which the solution drained contained little pyrite, and hence secondary silicates and carbonates were deposited to great depth.

Topography and Enrichment

The reader who has followed the discussion so far will have obtained a general idea of the close relations of enrichment to topographic development of the region. A few of the more important relations will be stated concisely and illustrated by figures.

Case I. Youthful topography with vigorous erosion in gullies. (Fig. 7.) The result is that the secondary sulphides are concentrated under the hills.

Case II. Extreme youth and very rapid erosion in the gullies; or uplift and rejuvenation of gully cutting. (Fig. 8.) Result, the valleys have cut into primary ore, and since the migration of the copper

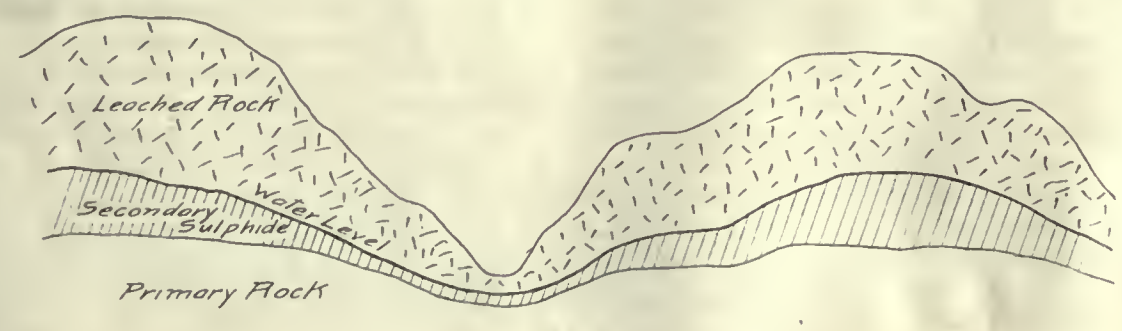

Fig. 7.

is slow the enrichment may be far above the water-level.

Case III. The country is stationary and the topography is mature. (Fig. 9.) Result is that the

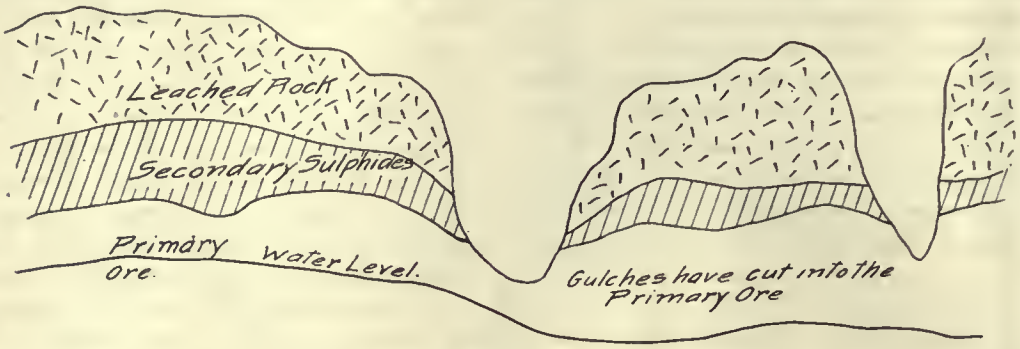

FIG. 8.

secondary sulphides have concentrated under the drainage lines, being much thicker here than under the hills.

These three cases cover most of the disseminated deposits; the Inspiration orebody, Arizona, comes under case I; Morenci, Arizona, illustrates case II, the deep gullies cutting far down into the zone of primary sulphides, and the enriched ore being far above water-level; the deposits at Ely, Nevada, probably fall in part under case III, the greatest deposits lying under Copper Flat.

The Iron Cap as an Indicator of Sulphide Enrichment

A long continued process of enrichment below, accompanied by the erosion of the surface, gradually destroys the prominent 'iron' outcrops. Many of the greatest copper mines have only insignificant outcrops (examples, Butte and Morenci), while many imposing iron caps of the Southwest overlie deposits of pyrite with only low content in copper, or develop over quartz-magnetite deposits where even the pyrite is scarce. The common practice of the prospector to judge the value of a copper deposit by the development of the iron cap is apt to lead to disappointment.

The Lava Cap Problem

A large number of the Western mining districts were flooded with lava after the primary mineralization had taken place, these flows occurring at various times. The moment that erosion exposes the primary deposit to the attack of surface waters, enrichment starts. The date of the formation of the primary ore deposits varies from the late Jurassic period through the Cretaceous and into the early Tertiary. In places where erosion has proceeded rapidly, surface waters may have been busy rearranging metals through Tertiary and Quaternary times. It is to be expected, therefore, that at the time some of the caps were formed, valuable secondary enrichment had been developed. The lava cap and the rise of the water-level necessarily accompanying the filling of the valleys, and the addition of a rock stratum, protect the deposit from further attack of surface waters until erosion has cut away a considerable portion of the lava. In several of the copper districts the problem has arisen as to whether the enriched ore extends under the remaining cap of lavas. The value of such pre-lava enrichments compared with that caused by both the earlier and later cycles may be judged to some extent by the relative amounts of pre-lava and post-lava erosion. In Fig. 10 the amount of rock attacked by post-lava processes (*b c d*) is small compared with that worked over by erosion during

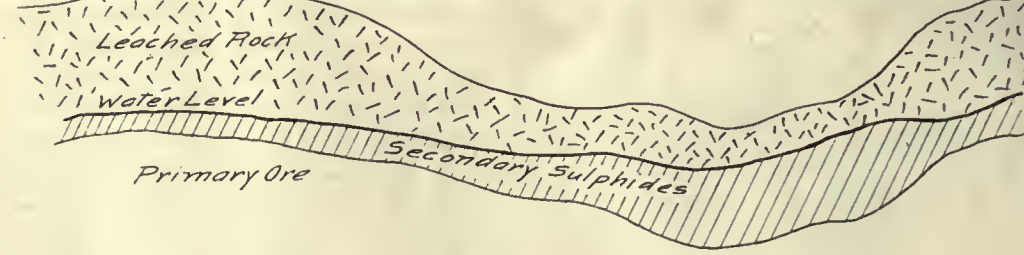

FIG. 9.

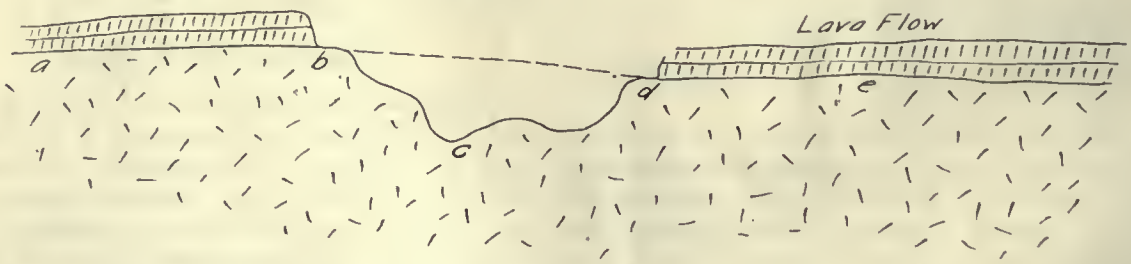

FIG. 10.

the development of the flat erosion surface *abde*. Therefore the chance of finding enrichment under the lava is good provided the primary mineralization extends out in this direction.

The Canyon and Delta of the Copper River in Alaska

By Lawrence Martin

The canyon by which the Copper river crosses the Chugach Coast range in Alaska is over 100 miles long and 4000 to 7000 ft. deep, the width varying from two and one-half to four miles. The heights specified are attained within one to three miles of the river. The Copper River canyon is, therefore, deeper in places than the Grand Canyon of the Colorado, with which it forms numerous contrasts because of profound glacial erosion. At its northern end is Wood canyon, which is apparently due to post-glacial incision following glacial diversion of the Copper river, rather than rejuvenation through warping as postulated by A. C. Spencer. The former Copper River glacier widened and deepened this canyon tremendously, as is shown by oversteepened valley walls, truncated spurs, and hanging valleys. The grade of the river in the canyon is 3½ to 5 ft. to the mile. The canyon terminates in a flaring lower section interpreted as a former fiord, now filled by the glacial sediments of the Copper River delta, whose area exceeds 500 square miles. On this delta detailed measurements of width and depth and of the rate of stream flow in the several distributaries furnish important data on the carrying power of glacial streams. Comparative studies in several show the rate of deposition and of erosion. Borings by the railway engineers show the nature of outwash material below the surface at several positions and depths on the delta. Vegetation below present sea-level in these borings proves recent sinking of the land. The existing glaciers of the Copper River canyon dominate the river in places, causing the deposition of outwash gravels in one area of over 50 square miles above a glacier dam. The distribution of present-day vegetation in the canyon suggests a recent pre-historic period of glacial expansion. (Read before the Geological Society of America, December 1912.)

Manganese mining in Russia is largely in the hands of Germans. The production has been considerably discouraged in the past by recent high freights, but when it is possible to get manganese cheaply from the Caucasus to the European markets the mines will no doubt promptly respond to the call. The production in the first half of 1912 was 120,032 tons, against 97,475 in the first half of 1911, in South Russia. Export from the Caucasus has largely increased this year.

Mercury reduction works at Bachmut, Russia, are to be reopened after having been closed for some time. Russia, once a well known producer of quicksilver, for a year or two fell out of the ranks altogether, but is coming back.

Concentration of Dissolved Metals in Slime Ponds

By M. W. von Bernewitz

A millman at Tonopah recently said to me, "When anybody states that there is no dissolved metal going out with the residue, I doubt it." And most people will agree with him. At Kalgoorlie, especially from the ponds consisting of finely ground roasted ore, the clear water floating off has at times assayed from 6 to 20c. per ton, and has been clarified, strengthened by addition of a little lump cyanide, and the metal content precipitated on zinc shavings. The water always shows cyanide by test, at one mine averaging 0.003% KCN. At another mine, lessees of the ponds did fairly well for a time; but on the whole there is little profit to be made in this way.

In *The Mining Magazine* for June 1910, G. B. Butterworth describes the sampling, erection of plant, and results of a dump of roasted ore which had been treated in the usual way at Kalgoorlie and discharged from cars. In this case, sampling was inaccurate, as "this is a case in which a portion of the gold in the residue was converted into soluble gold, in the presence of even such a small quantity of cyanide as remained after the final fresh-water washing, during the air-drying and subsequent handling, until it was buried in the dump. The rain soaking through would then be a solvent, and the sun would draw the moisture, carrying gold, to the outside crust; this would be deposited by evaporation as a soluble salt of gold."

In the Tonopah district quite a new industry has sprung up of late in recovering from the slime ponds the soluble silver salts which rise to the surface by the combined action of moisture in the dumps, heat of the sun, and capillary attraction, or in other words, evaporation of weak cyanide solution which carries dissolved metal. The salts form a crust with the top ⅛ in. of slime, and are collected by scraping with garden hoes or whisk-brooms. A great deal depends on the weather, and warm weather is most desirable. The value of the product depends on the care taken by the men in scraping it up, as digging too deep is like adding waste to ore. I was told that the *caliche*, as it may be called, varies in value from $30 to $130 per ton, and will average $40 per ton, while the cost of scraping and treatment also varies, since one man can collect 2000 lb. per day at $4, if the deposit is thick; but he will average only about 1000 lb. with the usual thin layer. Then there is the company's royalty to be paid which amounts to 35% in one instance. At the Belmont mill, at Millers, the *caliche* is sampled, fed into a tube-mill, and then mixed with the pulp, undergoing the usual treatment, while at the Extension it simply passes through with the ore after being sampled. One lessee ships his product to the Selby smelter at San Francisco. Even if the cost of collecting and treatment reaches $13 per ton (a figure given me as correct), there is a good profit in it for both the lessees and the companies.

Shaft-Sinking for the Rondout Siphon

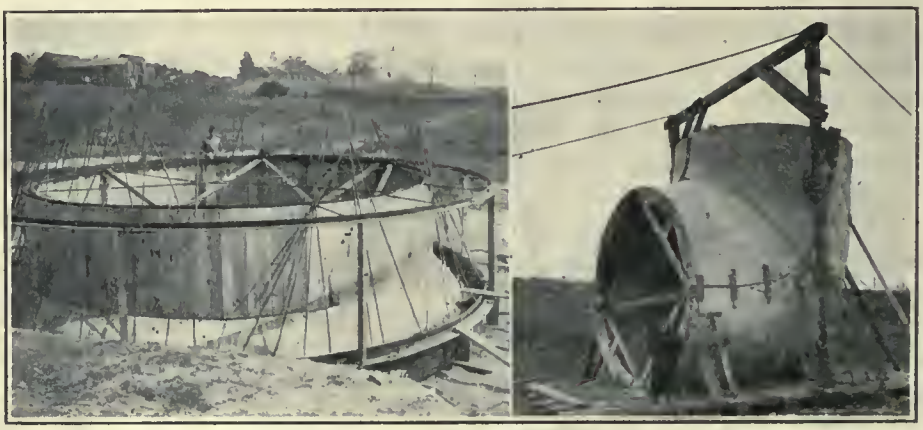
By J. F. Springer

*The sinking of shaft No. 4 for the Rondout siphon of the Catskill aqueduct has been described in detail elsewhere. It will suffice here to give only a brief account of some of the difficulties overcome. The strata which had to be penetrated were as follows:

	Feet.
Glacial drift	6
Helderberg limestone	226
Binnewater sandstone	39
High Falls shale	92
Shawangunk grit	134
Total	497

A 4-in. bore-hole had been put through the prism which the shaft would occupy. Water was to be expected in the sandstone and shale. However, long in advance of reaching the Binnewater sandstone, that is to say, at the 80-ft. level, water came in through the bore-hole, catching the contractor unprepared and flooding the shaft to the 40-ft. level. The water was pumped out to a point within a short distance of the bottom, and preparations made to fill the bore-hole with cement grout. A nipple was driven in and casing attached. Within this a 1-in. pipe was put down to about the level of the grit, 363 ft. below the surface. The water was then permitted to return, thus eliminating currents. The cement grout, made 1 to 1, was now put down the pipe, the purpose being to seal up the hole and its ramifications. As the grout was put in, the pipe was withdrawn. This hole seems to have given no further trouble. However, fears were entertained as to trouble below. These fears were abundantly realized, although no additional trouble of an especially serious character from water appears to have arisen until after the attainment of the 260-ft. level. At this moment only about 225 gal. of water per minute was coming in. However, while the sump was being drilled, there occurred a sudden inrush of 600 gal. per minute through one of the drill-holes. A second flooding now took place, apparently because of this flow through one small hole. The shaft was then unwatered, only to be flooded three times more in as many weeks. Water had now conquered five times. Large openings in the rock were ascertained to exist only a short distance below the point of excavation. One 8-in. crevice was only 1½ ft. below. If 2-in. bore-holes gave so much trouble, what would happen when larger openings were exposed? Effective preventive measures were imperative.

It was determined to attempt to seal the openings and connections with cement. Four grouting machines were set up at the surface, and 2½-in. piping with terminal 2-in. delivery tubing was put in place. When grouting was begun, trouble was experienced with back-leakage. This was overcome by mixing finely ground horse-manure with the grout. A total of 2900 bags of portland cement was used in the sealing operations. A few more holes were drilled and some additional cracks filled, 60 bags of cement being thus consumed. It was not deemed advisable to proceed with the excavation until further precautions were taken. There was still a distance of 100 ft. to the grit. Six drill-holes, three yielding 1-in. cores, and three 8-in. cores, were now put down through the intervening material, and the grouting processes again carried out. The pressure employed was 275 lb. per square inch; still only 175 bags of cement was consumed. This amount was so small comparatively that it was a question whether the problem had been an easy one, or whether it had been only imperfectly solved. Sinking was, however, resumed, and a depth of 320 ft. reached without serious mishap. A couple of collecting-rings had been arranged, and the shaft was nearly filled with sinking-pumps. It was now determined to construct a special pumping chamber to one side, and to install in it a powerful plant. Before these plans were carried out, however, the sixth and last flooding took place. The special chamber was situated at the 309-ft. level, and had a height of 10 ft. and a floor area of 17 by 24 ft. Underneath the floor a sump, 5½ ft. deep and 16 by 22 ft. in horizontal section, was provided. Its capacity was, therefore, 14,500 gal. In this chamber were installed three horizontal condensing pumps, built by the A. S. Cameron Steam Pump Works, New



STEEL SHOE FOR CONCRETE CAISSON, SHAFT No. 2. FORMS FOR DOWNTAKE SHAFT.

*From *Western Engineering*, January 1913.

York City. Each of these was of the 24 by 10 by 20-in. size, and the combined capacity was 1050 gal. per minute. Steam was supplied by three 100-hp. boilers set up at the surface. It seems that this special chamber, with large pumping plant and sump, should have been provided at an earlier stage of the sinking operations. It would appear that if this measure had been taken at or near the 200-ft. level, provided that conditions permitted, only one flooding might have taken place. That this shaft earned the descriptive adjective 'wet,' will be readily granted from the foregoing and from the fact that 86,181,000,000 foot-gallons of water was pumped therefrom during the eighteen months of its construction. The total cement consumed was 971 barrels.

At shaft No. 1, the overlying earth covering the rock was 83 ft. deep. It was proposed to pass through this bed, consisting of bonider clay, by means of an open cylindrical caisson of reinforced concrete. It is said that this shaft might have been sunk with the aid of timbers. The concrete caisson was employed, however, for the reason that the specifications required the removal of all timber down to the ground-water level before putting in the permanent lining. However, for a short depth timbering was employed. Then, at a point 23 ft. below the surface, a steel riveted cutting-edge was constructed, together with an interior form, the latter to give shape to a section of the concrete caisson. The external cylindrical surface was formed by the clay wall of the excavation itself. In this way a caisson 25 ft. in height was constructed. There was then considerable weight resting on the cutting-edge.

Excavation by pick and shovel was then started, a derrick taking away the spoil. This caisson sank vertically until a depth of 26 ft. was reached, when it began to deviate from the vertical. In part, the disposition to lean was corrected by increased digging beneath the high side. When it had reached the 34-ft. level, the skin friction of the concrete against the clay became so excessive that undercutting of the steel edge was insufficient to cause it to descend. It seems that the contractor was not permitted to use either air or water in sufficient quantity to soften the sides. The reason for this restriction was based on the fear that surface settlement might result, and that thus difficulty might arise in connection with founding the heavy siphon chamber which was to be constructed later on. However, permission was granted to inject a moderate amount of water through the grouting holes of the caisson.

CONCRETE BULKHEAD NORTH OF SHAFT No. 4.

This procedure alone was insufficient, so it was determined to impose a load. Two hundred and fifty tons of earth was loaded on the caisson, using a suitable box as a retaining device. At length the 63-ft. level was reached. There was still 20 ft. between the cutting-edge and the rock below. It was now determined to concrete this section instead of attempting to force the caisson itself down to the ledge. Accordingly, the shaft was excavated to full size through this intervening region, and a central form set up, the clay wall acting as the outside form. When these preparations were completed, concrete was filled in, thus completing the lining of the lower portion of the earth shaft. The spaces between the caisson and the clay were filled with grout. It is thought that no appreciable settlement of the earth around the caisson took place. The same general method of sinking was employed in shaft No. 2.

Antimony shipments from the port of Hankow, China, increased in value from $92,692 in 1910 to $196,974 in 1911, of which $116,460 is represented by refined metal and regulus. Total shipments of antimony from Hunan province amounted to $505,645, exclusive of ore.

First Aid for Cyanide Poisoning

By W. H. Kritzer

Considering the large quantities of cyanide salt and solution handled in gold and silver-mining districts, and the poisonous nature of this useful compound, the number of deaths from its use are few. When a man has inhaled prussic acid gas, or swallowed some cyanide solution the poison acts quickly, and his life depends on prompt action. The gas, when pure, causes almost instant death; and when diluted with air, results in dizziness, faintness, and a depressing headache. Solutions also act quickly internally while with many men they act on the skin and produce eruptions which are painful.

If an employee has inhaled prussic acid gas proceed as follows: Dash water on the patient's face; start artificial respiration; make him inhale either a small quantity of ammonia, ether, or chlorine gas. The latter may be quickly made by sprinkling a small amount of chloride of lime on a flannel cloth moistened with acetic acid, and then holding the cloth to the nostrils of the patient. If poisoning is from swallowing cyanide solution, place the patient in a hot bath, if procurable, and apply cold water to the spine and neck, providing that no delays are permitted to intervene in carrying out previous instructions. Also, incite vomiting by tickling the back of the patient's throat with a finger or feather; by giving lukewarm water, or strong mustard and water; by using a stomach tube and hot water; or by physical means. Diluted solutions of ammonia, cobalt nitrate, peroxide of hydrogen, or freshly precipitated carbonate of iron may be given. The last mentioned is made by mixing equal parts of ferrous sulphate, and sodium carbonate, and then administering at once. The following may be also used, the apparatus consisting of one sealed bottle 30 c.c. of caustic potash; one sealed bottle containing 30 c.c. 33% solution of ferrous sulphate; and one sealed package containing oxide of magnesium. As quickly as possible, empty the contents of the two bottles and a package into a metal cup, and stir thoroughly with a metal spoon. If the patient is conscious, make him swallow the mixture at once, and then lie down a few minutes. If unconscious, place him on his back and pour the mixture down the throat in small quantities, if necessary pinching the nose in order to start swallowing. Then incite vomiting by one of the previous methods suggested. It is advisable to have a soft rubber stomach-tube having a funnel and exhaust bulb in a cabinet to be described, if the services of a doctor cannot be had promptly. It is advisable to have a physician prepare the solutions required, and prescribe the dose of each to be taken by a patient in an emergency; and to further assist in preventing mistakes, bottles of blue glass can be used for the acids, and of white glass for the alkalies.

In all cyanide plants it is important to have wood cabinets with compartments of suitable size in conspicuous, and easily accessible parts of the building, and preferably painted red. Have the emergency orders for the handling of patients fixed to the inside of the cabinet door, and properly label each bottle and see that the contents are kept in a fresh and pure condition. The four compartments should contain (1) one large bottle of distilled water; one large metal spoon; and a one-pint metal cup for mixing the different antidotes; (2) for external use one bottle each of ammonia, ether, acetic acid, chloride of lime (bleaching powder); and a piece of flannel cloth for administering the chlorine gas; (3) for internal use one bottle each of diluted ammonia, cobalt nitrate, ferrous sulphate, and sodium carbonate, the two latter to be fresh; and (4) one sealed bottle with 30 c.c of caustic potash, one sealed bottle with 30 c.c of 33% solution of ferrous sulphate, and one sealed package with oxide of magnesium. Another important point, now fortunately observed at most cyanide plants, is the erection of notice-boards in different parts, warning employees and others that certain tanks and pipes contain solution and others water.

Progress at the Nevada Wonder

By J. A. Burgess

The construction work which was begun by the Nevada Wonder Mining Co. late in October was finished early in December. The 70-ft. head-frame, and the double-drum hoist, with a double-deck cage, are now in operation and are working satisfactorily. At present only one cage is being used, and it is counterbalanced with a weight running in a box in the manway compartment. The head-frame is built of timber, with steel girders and posts at the top to support the sheave wheels, and is well tied with iron bolts and rods, thus forming a rigid structure, which has very little vibration when in use. The new 125-hp. double-drum hoist, made by the Joshua Hendy Iron Works, has a drum capacity for 1500 ft. of ⅞-in. rope. By operating two double-deck cages in balance at a speed of 400 ft. per minute, this will give all the hoisting capacity that the mine needs for the increased amount of work that is planned.

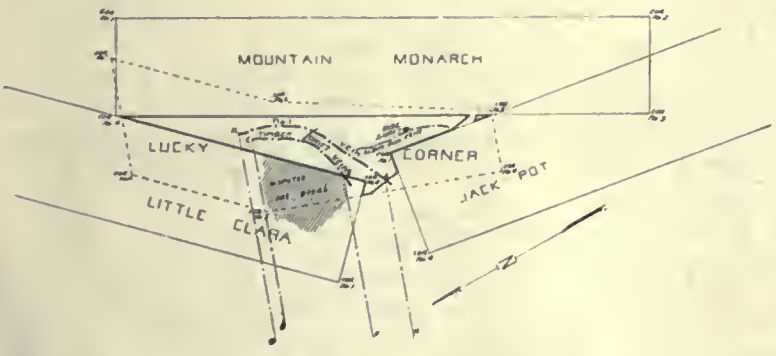
The hoist and compressor building has been moved into the excavation made for it, and has been enlarged sufficiently to contain another compressor. Five new mine-cars have been added to the equipment. A comfortable cottage has been built for the superintendent's use, and a stable has been built near the mine. With these changes and additions to the plant, the property now has first-class equipment. The work of enlarging the shaft by adding a second hoisting compartment from the 700-ft. level to the surface is now under way, and sinking the shaft from the 700-ft. level will be started in a short time. The general development work is decreased to some extent by the shaft work, but driving is now in progress on the 200, 500, and 600-ft. levels. During the month of November 3128 tons of ore was milled at a net profit of $19,466. Mining operations were stopped November 11 on account of the construction work, and for the remainder of the month the mill was run on dump ore, which accounts for the decreased earnings.

The Doctor-Jack Pot Case

The statement appearing recently in the columns of an Eastern contemporary that the devision in the case of Work M. & M. Co. *v.* Doctor-Jack Pot M. Co., recently decided in the Circuit Court of Appeals for the Eighth Circuit, had been affirmed in the United States Supreme Court, is not strictly true. The Supreme Court merely refused to issue a writ of certiorari in the case, and it has been repeatedly held that this is not to be construed as an affirmance of the opinion below. The case is of unusual interest and was discussed by H. V. Winchell in the *Mining and Scientific Press*, May 7, 1910. In view of its interest we present a further brief summary of the controversy.

The Doctor-Jack Pot M. Co. was the owner of the Lucky Corner lode claim in the Cripple Creek district. The Work M. & M. Co. owned the Little Clara lode claim. The relative positions of the two claims is shown in the figure below:

Claiming to be the owners by virtue of patent and mesne conveyances of the Lucky Corner claim, the Doctor-Jack Pot company alleged that the Work company had trespassed on an extralateral segment of the Timber Drift vein, having its apex inside the boundaries of the Lucky Corner claim. The defendants alleged: (1) that the Timber Drift vein in its course intersected the Lucky Corner side-lines, that said lines were not parallel, and that therefore plaintiff was not entitled to any extra-lateral right; (2) that no sufficient discovery had ever been made within the boundaries of the Lucky Corner claim prior to its patent, and that therefore the patent was void; and (3) that all mining done by defendants had been upon the Basalt Flat vein



PLAT OF CLAIMS.

apexing within the boundaries of the Little Clara claim and discovered long prior to any discovery within the Lucky Corner.

The principal question presented by the record was as to the right of defendants to attack the Lucky Corner patent by showing it to be unsupported by a discovery. On this point both the trial court and appellate court held that the findings of the Land Department as to a proper discovery were conclusive and could not be collaterally attacked subsequent to the issuance of a patent, stating:

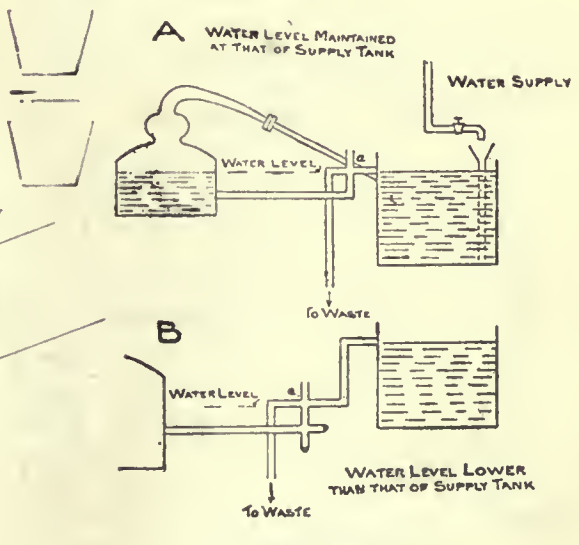
"It follows that the Land Department at the time it issued the patent necessarily passed upon the question, not only as to whether there was a discovery upon the claim, but whether such discovery was in the discovery workings, as required by the laws of Colorado, because the Land Department must take notice, not only of the requirements of the acts of Congress, but the local laws and regulations of miners as well. * * * Whatever may have been the right of the defendant to raise the question, by protest or other appropriate proceeding, of no discovery within the patented ground, prior to patent, that question was forever foreclosed when the patent issued, except by a direct proceeding to set aside the patent or to declare that the grantee therein held it in trust for some party having a better right."

With reference to the vein crossing the side-lines, it was held that this was not established by the evidence, and that in the absence of a showing to the contrary, it would be presumed that the end-lines fixed by the patent are the true end-lines, and that the vein ran lengthwise of the claim and not crosswise.

The evidence seems to have established the identity of the vein on which defendants were working with the Timber Drift vein. Judgment for the Doctor-Jack Pot company was accordingly affirmed on appeal. The decision is in line with the general policy of the courts to accept as final findings of the Department of the Interior as to fact.

Level Regulator

The device figured below was described at a recent meeting of the Chemical, Metallurgical & Mining Society of South Africa. The diagram shows the device fitted between a condenser and a still,



WATER-LEVEL REGULATOR.

and serves to keep the still filled to a constant level with hot water from the condenser. If the condenser is of ample size and the water-supply suitably regulated, the water entering the still will be nearly boiling, complete condensation will be maintained, and very little water run to waste. When hard or dirty water is in use, T or cross-pieces can be introduced at convenient points for cleaning, as illustrated in diagram *B*. The water-level within the still may be at or under that of the condenser and is regulated by that of the crosspiece *a*. The crosspiece could be connected to its supply and delivery points by flexible tubing and the water-level would then be subject to immediate control by raising or lowering the crosspiece.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Geological Mysteries

The Editor:

Sir—Isn't this a gem? It is from a report by a man signing himself "J—— G——, *Prac. M. E.*":

"The mineralized zone is the same Rhyolite, a mere composition of mother earth formation, consisting of lime Porphry and Hematite of Iron, subject to decomposition and reciprocation."

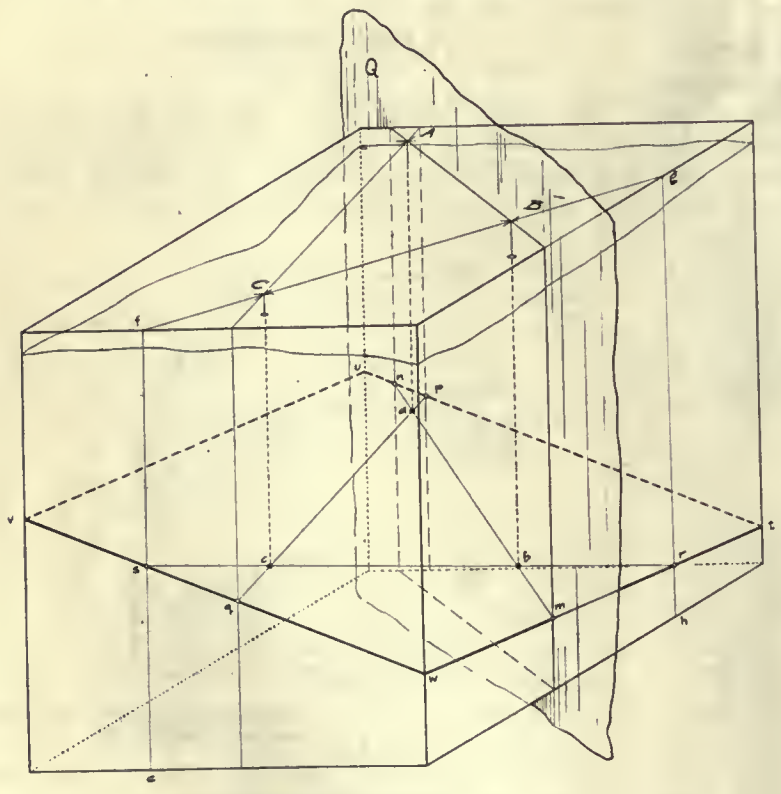
ALEXANDER LEGGAT.

Butte, Montana, January 8.

Graphic Representation of Oilfield Structure

The Editor:

Sir—In response to the request for additional details regarding graphic representation of oilfield structure, discussed in your issue of December 28, I give below a brief outline of the method that is used in plotting a formation of interest in a stereogram.



STEREOGRAM OF OILFIELD STRUCTURE.

For the sake of brevity, only three points are taken (*a*, *b*, and *c*) which might be considered as the upper limit of oil in the three wells *A*, *B*, and *C* (see figure). Imagine a vertical plane *Q* drawn through two wells, *A* and *B*. A line drawn through points *a* and *b* (oil-sand) will lie also in the plane *Q* and, prolonged, will intersect the two border planes in the points *m* and *n*, which will be on the intersection lines of the plane *Q* with the lines of the block. Similarly, two other vertical planes (not shown on the drawing) drawn through *B* and C, and *C* and *A*, will locate the points *p*, *q*, and *r*, *s*, on the border planes. In connecting these points (*m*, *r*, (*t*), *p*, *u*, (*u*), (*v*), *s*, *q*, and (*w*) *s*) with straight lines we obtain the outside rim of the oil-sand, shown by a full line on the front planes and in dotted on the back planes. Evidently, the drawing of the vertical planes is reduced to the drawing of three lines, *gh*, *fg*, and *fe*, which simplifies the whole construction.

Vacuum-Filter Improvements

The Editor:

Sir—I was interested to read in your October 19 issue of the success attending the introduction of the method of simultaneously replacing the pulp with wash solution in the working of the stationary type of vacuum-filter at the Concheño mill, in Mexico. H. G. Smith, who describes the innovation, takes undue credit to himself as the originator of the idea. *The Engineering & Mining Journal* of May 15, 1909, contains an article of mine explaining the system and its advantages, and outlining a scheme for continuous operation. For some time previous to this, I had worked the method with considerable success in northern Mexico. In the concluding paragraph of his article, Mr. Smith presents the idea to his co-workers. This indicates a commendable spirit of generosity, but I would like to add that the improvement in question is protected in Mexico by Patent No. 8814, which was granted me on February 3, 1909.

Lubricating Oils and Warm Solutions in Cyanide Practice

The Editor:

Sir—During the hot summer months on the desert it usually requires some extra effort toward conserving the limited water supply in order to meet the requirements of a milling plant. At the King of Arizona mine an endeavor was made to meet this condition by laying drains from the boilers, engines, pumps, and hoists to convey all waste water, and incidentally a large portion of the waste oil, to a common sump. As occasion permitted, the water from this sump was added to the working solution by pumping it as a final wash upon a leaching vat, thus leaving the oil deposited on top of the sands.

The Mexican hoist men had observed the oil floating on the vats from time to time, and seemed to me to show uncommon zeal in the matter of allowing waste oil, oily refuse, cotton waste, etc, to slide into the sump. They had evidently concluded that this was a new departure in cyaniding and presumably had something to do with lubricating the

path of the gold through the vats into the refinery. At least a protest against so much oil being thrown into the sump elicited the quick response: "*Pero aceite se necessita para sacar el oro mas pronto no?*"

Exhaust pipes from the solution and vacuum steam pumps in the refinery were laid to the weak solution sumps and arranged to exhaust beneath the surface of the solution. By this means the mill was usually abundantly supplied with steaming warm weak solution charges. In discussing the effects of warm and hot cyanide solutions, late reference books on cyanide practice seem inclined to disparage any benefits to be derived from such procedure. Clennell[1] says: "In some cases it has been found that higher extractions are obtained by the use of hot solutions at a temperature of say 100° to 130°F. and provision is

KING OF ARIZONA MILL.

sometimes made for heating solution or slime pulp by the injection of steam. In most cases it is doubtful whether the improved extraction outweighs the increased cost." H. W. MacFarren[2] adds: "In practice it has generally been impossible to note any difference between the normal extraction and that made by heating the ore and solution, or that obtained during the heat of summer or the frigid weather of winter."

I wish to state here that heating the solution was done less with the expectation of directly increasing the dissolving power of the solution, than to increase the rate of percolation, thereby facilitating more thorough drainage, hence a better aerated charge, and an increased number of solution charges within the treatment time allowed. Each vat was given a 7 days solution treatment. A marked decrease in the percolation rate was noticeable toward the close of the treatment period, due to packing of the sand. This was especially troublesome in the vats nearest the mill, but was largely compensated by using warm solutions toward the end of the treatment. As the mill was treating 200 tons daily a saving of 20 to 30c. per ton by utilizing waste heat proved a profitable innovation amounting to a considerable sum at the close of a month's run. While it is possible there may have been a slight loss of cyanide due to discharging the hot oily steam into the solution, such losses were not detected.

[1]Clennell, 'The Cyanide Hand Book,' p. 239.
[2]MacFarren, H. W., 'Cyanide Practice,' p. 15.

Regarding the effect of cyanide upon oils, Clennell[3] says: "Cyanide is also a solvent of oily and fatty matters, but probably only by virtue of the free alkali it may contain." It is of interest here to note also the effect of an electrolyzed cyanide solution upon oils as observed by J. H. Aldrich, Jr.[4]; "Grease in the ore or on the surface seems to dissolve very rapidly in the treated solution and slowly in the untreated solution. We tarred our tanks inside and coated them with black oil outside, and more or less grease was frequently floating upon the surface of the solution, where the effect was noticed."

Bottle tests were prepared as follows, and the solutions covered with oil and occasionally agitated.

	I. Cylinder oil, per cent.	II. Engine oil, per cent.
Free KCN	0.20	0.20
Total KCN	0.20	0.28
Protective alkalinity	0.08	0.05
AFTER 24 HOURS		
Free KCN	0.20	0.20
Total KCN	0.20	0.26
Protective alkalinity	0.08	0.07
AFTER 48 HOURS		
Free KCN	0.20	0.20
Total KCN	0.20	0.26
Protective alkalinity	0.10	0.08

A final titration in 96 hours gave similar results, with a still further increase in alkalinity. In two other tests from different lots of oils quite a copious white precipitate formed, but the general results did not in the main differ from those given.

J. E. CLARK.

Riverside, California, December 9, 1912.

Hendryx Agitator on the Rand

The Editor:

Sir—I note in your issue of November 9, 1912, an article by H. Stadler under the head of 'Johannesburg Correspondence,' entitled 'Hendryx Agitator on the Rand.' I beg to state that from March 11, 1912, to May 2, 1912, five tests were made, of which Mr. Stadler was only in charge of two. Some of the statements in the article referred to are quite misleading and unfair. When the Mines Trials' Committee was requested by me to test the agitator, their secretary desired for the information of this committee to know what claims were made for the agitator and was informed that it would dissolve as much or more of the gold content of the Rand ore, sand and slime together, in one hour as ordinary leaching methods would dissolve in twenty-four; that the loss of cyanide during the period of agitation would be less than in percolation to dissolve the same amount of gold; that the power would not be excessive, that the agitator would start readily after a long period of settlement; that the slime contained in the ore, owing to the rapid and violent agitation, would be coagulated instead of emulsified, and would more readily settle or filter than when air agitation was used. The official report which the committee has been courteous enough to allow me to publish I hereby enclose.

[3]Clennell, 'The Cyanide Hand Book,' p. 184.
[4]*Trans.* Amer. Inst. Min. Eng., Vol. XLII, p. 746.

It is not necessary for Mr. Stadler to give the apparent reason for the non-publication of the tests by the Mines Trials' Committee, as no one is better aware of the fact than he that it is neither the custom nor the policy of the committee to publish results of its tests. It is very necessary that the committee protect itself against misrepresentations and the rule of not publishing such tests, I understand to be a policy of protection to themselves. Knowing that I had come a long distance and had expended a large amount of time and money, and that no misrepresentations would or could be made, they had the courtesy to permit me to print the tabulated report above referred to.

The comparison Mr. Stadler attempts to make of my 18-ft. agitator with the 400-ton leaching tank is not only unfair but absurd. Had the committee desired to ascertain how many tons could actually be put through the 18-ft. agitator in twenty-four hours, otherwise than by comparison after the assaying of the solutions and wash residues at different periods, it undoubtedly would have installed dewatering or thickening tanks as storage ahead of the agitator and decanting or filtering apparatus after the agitator, so the time of dewatering, filling, and discharging could be reduced to a minimum; an expense entirely unnecessary in order to ascertain what the committee desired to know. Also, it would have installed a large size 24-ft. agitator, holding 100 tons of solids and 200 tons of solution with proper arrangement for filling and discharging, and would have treated four charges per day of the coarse material, which would have been 400 tons in twenty-four hours as against 400 tons of Mr. Stadler's leaching tanks in seven days. On the slime several times that amount could have been treated.

WILBUR A. HENDRYX.

New York, December 4, 1912.

[Mr. Hendryx is in error in supposing that the article referred to is by Mr. Stadler, as it was sent us by our regular Johannesburg correspondent. In our issue of last week Alfred James speaks forcefully concerning the policy pursued by the Mines Trials Committee.—EDITOR.]

OFFICIAL REPORT, MINES TRIALS COMMITTEE.

East Africa has not yet been geologically surveyed, but coal has been found near Mackinnon Road station on the Uganda railway. The outcrop, however, has not been traced, though the field is being examined by a geological expert. The enormous soda deposits lying in the bed of the 'soda lake' of Magadi will soon be shipped to market. The railway to connect the deposit with the Uganda railway is now under construction, and work is also in progress looking to the providing of deep-water facilities at Mombasa, which will be required to take care of the output when the movement to market begins. Additional equipment is also being ordered by the Uganda railway to meet the anticipated requirement for cars and engines. During 1912 the Busoga railway, from Jinja, on Lake Victoria, toward Lake Kioga, was completed. This forms a small but important link in the Cape-to-Cairo railway project, and also opens up a valuable cotton territory. It is the first piece of railway in the Uganda Protectorate, the Uganda railway being entirely in the East Africa Protectorate.

Special Correspondence

NEW YORK

THE COPPER SITUATION. — BREITUNG MINES CORPORATION. — MIAMI DISTRICT.

The report of the Copper Producers' Association for December rather upset the calculations of those who had proclaimed that the deadlock existing in the copper-metal market had been broken. It had been anticipated that production figures would show a substantial diminution as a result of the curtailment of operations caused by the strike and the labor disturbances at the Utah Copper Co. and the Nevada Consolidated; but instead of showing a decrease, the production was nearly at a record level, amounting to 143,354,042 lb., a figure which has been exceeded only twice during 1912. The export demand took up 65,713,796 lb., which is well up to the average monthly shipments for the year, the domestic consumers taking 58,491,723 lb. These figures reflect in some degree the unwillingness of American consumers to come into the market at present prices. The resulting increase of 19,148,523 lb. somewhat more than justifies the attitude of manufacturers at home in their position that, so long as the producing and selling interests insist upon maintaining a price of 17¾c. for copper, they must carry the metal for the consumer. It is hardly worth while to try to stampede the consumer into the market as long as surplus stocks show substantial increases. There is still such an intense feeling of uneasiness abroad that it is hardly to be expected that any abnormal demand will spring up, at least such a demand as will have its source in consumption of copper other than that used by the various governments in their preparations for war, and it is undoubtedly true that so far as this particular demand is concerned it has already been provided for in large part. Consumers at home are fully justified in their continuance of the so-called hand-to-mouth policy.

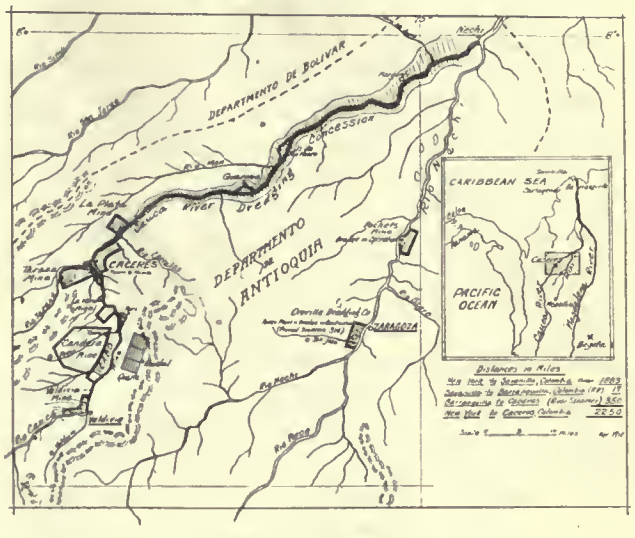
The Calumet & Hecla is almost the only large producer that shows a decrease in production for 1912 as compared with the year preceding, and with the development of the Ahmeek and the splendid work that has been going on in increasing efficiency, it is anticipated that this decrease will be turned into an increase in 1913. One of the principal items in the work of the efficiency department has been the supplanting of the old two-man drills in the Calumet & Hecla by new one-man machines. The Calumet & Hecla now has 90 drills of this type at work, each machine doing exactly the work heretofore done by the two-man machine.

The Dern interests of Salt Lake City have formed the Mines Operating Co. to work the property of the Ontario Silver Mining Co. on a royalty basis. One of the most pretentious attempts at mining finance put forth within recent months in New York is the organization of the Breitung Mines Corporation by Breitung & Co., Ltd., with a capital of $10,000,000, to operate in the Cauca and Nechi valleys in Colombia, South America. It is said that a large amount of prospecting has been done and that the new company expects to develop aggressively along the same lines pursued by the Oroville Dredging Company.

The making of another important copper producer for the Miami district seems highly probable. The South Live Oak Development Co. has two drill-holes in commercial ore, one at a depth of 535 ft.; a second drill-hole also went into the ore at 535 ft. In one hole the orebody showed a thickness of 90 and in the other of 95 ft. Assays show an average copper content of about 2%. Drill-holes are being sunk at intervals of 200 ft. with the idea of outlining the entire orebody.

The Arizona United Mining Co., operating at Johnson, in Cochise county, Arizona, and controlled by Philadelphia interests, reports the finding of a good body of sulphide ore in the bottom of a winze 50 ft. below the eighth level in the Republic mine. The Arizona United has been endeavoring to get on a basis of production, having been obliged to suspend early in 1910 when the copper-metal market was at such low level as to make any profit impossible. The property is equipped with a 125-ton smelter, and in the course of development has produced something over 500,000 lb. of copper.

The Mexican Metals Co., the corporate successor of the Arizpe Mines Co., is one of the specialties of the open market in Boston. The company controls some 6500 acres of mineral land lying about 39 miles south of the United States border and some 15 miles from Cananea, Mexico. The property is equipped with a 100-ton mill, but this capacity is to be largely increased in a few months, the company's treasury having already been provided with



PART OF COLOMBIA.

funds necessary to add the new equipment. George E. Keith, a large shoe manufacturer of Brockton, Massachusetts, together with B. P. Cheney and his associates, control the property.

BOSTON

THE BRADLEY PROCESS.—MASON VALLEY SMELTING.—FRANKLIN MINING.

Lawson's Trinity and Curb stocks, First National, and Bay State Gas, fluctuate now principally in accordance with the news received from the workings of the Bradley process at the Washoe smelter. A. C. Burrage expended something like $250,000, it is said, on an experimental plant for the Bradley process to treat the slime containing about 2% copper, at Anaconda. This was nearly a year ago, and ever since that time Boston has been receiving varying advices about the progress of the process. It is said that mining and smelter men in Butte look on the experiments askance, yet with no little interest, believing that they will not be successful. Some time ago a news bulletin was sent out stating that the thing was practically a failure. Now it is claimed by the promoters, Lawson and Burrage, that the process is running fairly satisfactorily and that the difficulties, entirely mechanical, are gradually being overcome. The news that the process was a success at Anaconda would probably add more to the market selling price of Trinity, First National, and Bay State Gas than a Lawson advertisement, even though it occupied a half page or a page, could accomplish. A successful demonstration of the Bradley process at Butte will foreshadow its installation at the Balaklala smelter in the Shasta district and the resumption of mining at First National, with the possible resuming of shipments at Trinity.

The Mason Valley smelter is now handling about 850 tons of ore and shipping out about 60 tons of copper matte per day. The operation of the smelter has encouraged mines to start shipping throughout the Mason and neighboring districts, with the result that the custom business has increased very materially during the past year. It is

expected that this increase will keep up during 1913. Before the smelter was started, the company, reported to be fearful that it did not have a sufficient supply of ore and fluxes to depend upon otherwise, took the precaution of making a contract with the Nevada-Douglas company to ship 250,000 tons of ore. When this contract expires there may be some new developments in the Mason district. The Nevada-Douglas people are understood to be dissatisfied with the cost of smelting their ore at the Thompson plant and have long been considering the building of their own smelter in Smith valley. It may turn out that by the time Nevada-Douglas has completed its contract of shipping 250,000 tons to the smelter, the smelter people will be in receipt of ample ore mixtures from other sources and the Nevada-Douglas interests may be ready to build their own smelter. At any rate, there is the very likely probability that the mining and smelter situation in Mason or Yerington will greatly expand from now on. The Mason Valley people are considering the installation of two stands of converters, and experiments will be made with the view of reducing the cost of fuel at the plant.

The adjourned special meeting of the stockholders of the Franklin Mining Co. was held on January 8, about 45 stockholders being present. This meeting followed one which failed to arrive at any agreement in December. The motion was offered that litigation should not be started against Messrs. Edwards, Tolman, Howard, Watson, or Wyman, directors, and that litigation against Dow and Bailey be deferred until the question could be taken up at the company's annual meeting. It is claimed that litigation is hardly advisable because recovery of money is neither sufficiently certain in law nor sufficiently great in amount to justify the proceedings. The motion was carried by a vote of 105,901 shares in favor to 460 shares against.

OURAY, COLORADO

Changes at Wanakah.—Customs Zinc Mill.—Ouray Club.

The Camp Bird is pushing development of the new orebody, with reported favorable results, and the mill is still operating at part capacity. At the Wanakah the mill continues to operate at full capacity and the management has been carrying on extensive development and exploration in the mine for some time. Amalgamating, re-grinding, and slime concentrating apparatus have produced such improvement in milling that considerable additions will no doubt be made to the mill this spring. The Atlas has been operating regularly on the usual basis and is now supplying a large part of the concentrate treated at the custom zinc separator. The Barstow has closed its mill for the winter, after a successful season, and is carrying out a scheme of exploration and development of greater extent than for some years past. A long raise is being driven.

The Humboldt and Mountain Top, the two most important new companies in the district, successfully transported and placed their machinery, and are now active in exploration and development; the Mountain Top has begun its 2000-ft. adit and three shifts are making good progress. The Humboldt has large ore reserve, which promises well for a new mill next year, sinking and driving is in progress. The custom zinc mill, erected and operated by David Foerster, using Huff electrostatic machines, has made a good record on Barstow and Atlas concentrate, and is operating steadily on this material. The Revenue Leasing Co., leasing the Revenue Tunnel property, was forced to close its mill on account of difficulties in milling during the winter, but announces that work will soon be resumed.

The Ouray Commercial Club, at its meeting of January 8, outlined an ambitious plan of work for the coming year. The year 1912 closed with more activity along the line of real mining than has been shown for some years past, and the year 1913 promises improvement. The bureau of mines of the club is beginning an active campaign along various lines, and will make a point of giving reliable information, or none at all, and is soliciting inquiries. John T. Roberts, Jr., is president of the club, and C. R. Wilfley, of Ouray, is chairman of the bureau of mines of the club.

PORCUPINE

Production for Year.—Changes at Dome.—New Mills.

In Canada, east of the Rocky Mountains, there are at the present time only two mining districts in which the general public is vitally interested. These are Cobalt and Porcupine. The former has been a steady producer since 1905 and has assumed such proportions that from an area of approximately 7 square miles the annual output is over 30,000,000 oz., taking high place among the silver-producing districts of the world, Canada being exceeded only by the United States and Mexico. While Cobalt has shown a decrease of about 1,000,000 oz. during the past year, the high price of silver has created a new record for the value of the total production, approximately 50% of which has been paid in dividends.

The newer Porcupine district has just emerged into the producing stage, the output for 1912 being valued at about $1,750,000. The unofficial figures for the production are: Hollinger, $900,000; Dome, $700,000; and the McIntyre and Vipond, $150,000 between them. Practically all of this output is credited to the last six months of the year, and on account of the mills being new and many changes necessary, it is hardly a fair criterion of what may be expected during 1913; in fact, it is fairly safe to assume that during the present year the total production should reach a value of about $5,000,000.

At the Dome a new tube-mill and filter-press are being installed, and with these in commission the capacity should be increased from 10 to 15%. In addition to this, the company is seriously considering doubling the capacity of the plant, but the labor troubles have interfered to such an extent with the development work, on the results of which additions would be authorized, that it is doubtful if the enlarged mill will be in a position to have much influence on next year's production. In the same vicinity as the Dome is the Dome Lake, where a 10-stamp mill is being erected. This should be in commission by next March and will have some influence on the year's production.

At the other end of the district is the Hollinger mine. The production from this property has been mainly from 30 stamps. Another 10 stamps has been added, however, and, as the mill is now running smoothly, this property, if the present grade of mill-feed is maintained, should during the coming year contribute practically 50% of the total output. In the same neighborhood as the Hollinger is the McIntyre. This company has been operating a 10-stamp mill since last February, and it is now working on a new mill which will have an estimated capacity of 150 tons per day. As a cyanide plant is also being constructed, its production in 1913 will be considerable.

The Vipond mine, in the Pearl Lake area, also has a small mill. Its estimated capacity is about 100 tons per day, but under present conditions it is unable to treat more than 50 tons. The company is considering the erection of a cyanide plant. Of the present non-producing mines, those that may be expected to become producers in the near future are the Miller-Middleton, Dixon, McEnaney, Jupiter, and Plenaurum. The first two are owned by the same people who control the Hollinger, and it is not at all unlikely that when development work has progressed sufficiently to permit of an estimate of their probable value they will be amalgamated with the Hollinger. At the McEnaney, a 10-stamp mill is being erected and should be in operation in a few months. The Jupiter and Plenaurum companies are also considering the erection of mills, but it is doubtful if they will be sufficiently far advanced to make any showing in the year's production.

While at the present time there are only four milling plants in operation in Porcupine, the end of this year should see at least eight either in operation or in course of construction. While no new finds of importance have been made during the past year either in Porcupine or the surrounding townships, the possibilities of this district are by no means exhausted, and considerable life as an important producer may be expected. This district offers the distinction of being the first gold-mining district of Ontario which promises to be a commercial success.

BLACK HILLS, SOUTH DAKOTA

WEDGE ROASTER.--BISMARCK CYANIDE PLANT.—BLACK HILLS SMELTER.

The increase in production for the year in South Dakota, as estimated by the Director of the Mint, is cause for congratulation to the Black Hills operators. According to these figures, South Dakota's total yield of gold and silver was $7,917,832 for the year, as compared with $7,536,268 in 1911, an increase of $381,564. In arriving at these figures I have calculated the silver at $0.60835 for 1912 and $0.53304 for 1911, as the average price per ounce for the years mentioned. The increase in the value of silver was largely responsible for the gain in the silver production, for, although the silver yield was only 496 oz. greater in 1912 than in 1911, the value was $15,386 greater. The Homestake made the largest gain of any of the Black Hills properties, its yield for 1912 being $578,000 greater than in 1911. The Wasp No. 2, Trojan, Golden Reward, New Reliance, Victoria, Black Hills Standard, Monarch, and Richmond all showed increases, the Trojan making the largest gain, with $80,000. The production of the Mogul fell off at least $200,000, as a result of the company losing its big mill at Pluma, which was destroyed by fire in March, the balance of the year the company shipping a small tonnage to Lundberg, Dorr & Wilson. Several new mills are in course of construction, and the present year's production will probably exceed that of the past year.

The Homestake company has commenced work on a large dry-house at the Ellison hoist, and with its completion the number of employees using this shaft will be materially increased. The Golden Star shaft, which in the past has been used largely for hoisting men, has been settling and twisting, and it will not be used so extensively in the future. The Wedge furnace plant of the Golden Reward company has been put in commission, an expert sent by the manufacturers arriving early in the month to get it in shape. Construction work is finished, and all that remains to be done is to get the method of operation arranged to suit the ores. The furnace is of the ordinary pattern as made by the Wedge people, and uses crude oil for fuel. This oil is secured from the Wyoming fields, being hauled about 300 miles. The Detroit interests in the Golden Crest company, against whom the English interests, represented in the Hills by F. W. Bird, secured a judgment for $120,000 and costs in the circuit court here in October 1910, are evidently desirous of redeeming the property and paying off the encumbrance. Under the law of South Dakota a judgment debtor may secure an additional year's time for redemption by paying the costs, interests, and taxes in full for the first year. This the Detroit people have done. This payment necessitated the disbursing of $24,044.49, of which $19,513.20 was paid to Mr. Bird and his attorneys, Kellar & Stanley, of Lead, and the balance, $4,513.29, was paid to the county treasurer of Lawrence county, for taxes in full.

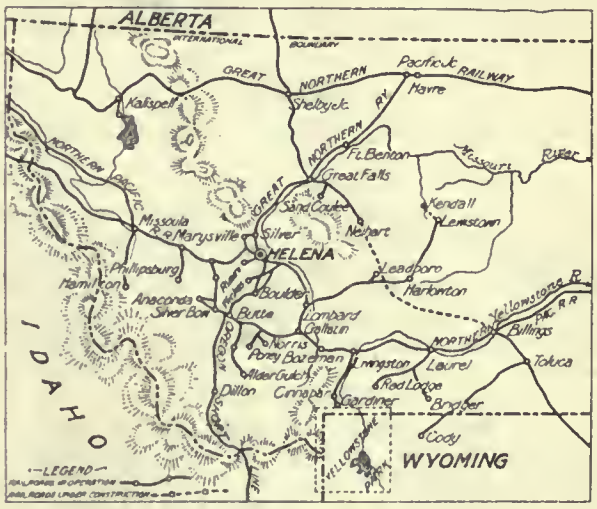
The crushers at the new cyanide plant of the Bismarck company, adjoining the Wasp No. 2, have been started, as the first stage in limbering up the plant and preparing it for operation. The necessary adjustments of the entire plant will probably consume two or three weeks time, and by the end of January it is hoped to have the whole plant in harmonious operation. The entire plant is electric driven, and taken as a whole is well constructed and should achieve good results. The process is much similar to the Wasp No. 2: coarse dry crushing in rolls and cyanidation of the product without classification. The mine is being arranged for working by the glory-hole system, the orebody lying nearly horizontal. The ore is exposed for a thickness of 75 ft. in the open cut, and about 10 ft. of stripping lies above this orebody. The waste is dropped through a winze separate from the ore winze. The mining method should be very economical on this basis, and the entire cost of mining and milling should be between $1 and $1.10 per ton.

E. J. Walter has arrived to assume the position of superintendent of the Black Hills Smelting Co., which has recently completed a plant at Galena. Mr. Walter has investigated the supplies of flux and ores, and believes that he will soon have contracts and a six months' supply for the plant. Pyrite will be secured from the Gilt Edge mine, 15 tons per day in the form of concentrate, and 10 tons per day in the form of heavy iron pyrite; copper ores will come from the Jungle mine, in the Custer Peak district, which is developed to produce easily the 10 tons per day that will be needed; dry ores will come from numerous properties at Galena and Bald mountain; limestone will be secured from a quarry on the hill at the rear of the smelter.

BUTTE, MONTANA

BULLWHACKER LEACHING PLANT.—RAILWAY ELECTRIFICATION.—LIABILITY LAW.

The leaching plant at the property of the Bullwhacker Copper Co. was started on January 6, at least experimentally. It is yet to be determined to what size the ore should be crushed to give the best results by leaching. It is planned to pass the solution through the ore at least twice in an endeavor to bring the copper content of the solution equal to that of the ore, or about 2%. The solution will then be transferred to the electrolytic precipitating-boxes. Those responsible for the plant seem confident of success, and expect to make a 95% saving at a total cost for mining and treatment of 7c. per pound of copper



WESTERN MONTANA.

produced. It has been stated that the ore to be mined will average 3% copper, which would mean a mining and treatment cost of $2 per ton on the above estimate.

According to John D. Ryan, president of the Great Falls Power Co., the Chicago, Milwaukee & St. Paul railway is to be the pioneer among the transcontinental railways in electrifying its main line. Mr. Ryan predicts that this will be the preliminary move in the final electrification of 10,000 miles of Western railways throughout the mountain and coast states. This statement comes as a result of the permit just granted the Great Falls Power Co. by W. L. Fisher, Secretary of the Interior, giving it the right to extend its lines over public land for the purpose of supplying railway lines with electric power. This grant is for 50 years and involves reasonable compensation to the Government. It is stated that steps are to be taken at once to electrify the main line of the Chicago, Milwaukee & St. Paul railway from Harlowton, Montana, to Avery, Idaho, and that $5,000,000 has been set aside by the railway company for that purpose. One of the main reasons for the recent consolidation of power-plants in Montana now becomes apparent, as it would be impracticable for a transcontinental railroad to be dependent on one source of power. By having the Thompson Falls plant, the Great Falls plants, and the Madison River plants lead into the same transmission-line, it is improbable that all sources of supply would break down at the same time.

An important measure is to be presented to the State Legislature, now in session, covering the liability of employers and compensation for workmen. The Butte Miners' Union has appointed a committee of three to lobby for

the measure in Helena. The bill as drafted is similar to the one now in force in the state of Washington.

At the recent annual meeting of the Butte-Milwaukee Mining Company, the controlling interest in the property passed to directors in Duluth, Minnesota. This was to be expected in view of the fact that the Butte-Superior Copper Mining Co. came into possession of the 250,000 shares of Butte-Milwaukee stock as a result of the completion of its contract of sinking the Sellers shaft from the 700 to the 1200-ft. level and driving a cross-cut to the Black Rock shaft on that level.

Glendive, in Dawson county, is having an oil excitement within its city limits, like Los Angeles. The Montana & Wyoming Consolidated, a Sheridan, Wyoming, company, drilled the well which is causing the excitement. Exactly what success was had is not forthcoming, but rumors are to the effect that companies are being formed and available land is being plastered with locations.

The Chicago, Milwaukee & St. Paul railroad has a large force of surveyors at work west of Great Falls, apparently working on a reconnaissance for a through line across the continental divide into the Big Blackfoot country and on to Missoula. It has been stated that such a line can be built on lower grades than the present one through Butte, and will reduce the distance from St. Paul to Seattle by 100 miles. A mineral district of some promise, heretofore without railway facilities, would be opened by the new line.

LONDON

WORK AT GREAT COBAR.—DREDGING AT VILORO.—PAHANG TIN MINES.

Now that the Great Cobar copper mine in New South Wales, owned in London, has made a profit, even though a small one, it is opportune to trace the history of the English company. This company was formed in London in 1906 to acquire the Great Cobar copper mine in New South Wales. The purchase price was £800,000 in cash and £206,000 in shares. The reports on which the transfer was effected were made by J. D. Kendall, C. M. Roiker, and W. J. Barnett. The Lithgow refining works, near Sydney, and the Chesney copper mine were bought at the same time, and two years ago the Cobar Gold mine was acquired, the gold-bearing silicious ores of the latter making a suitable flux for the pyritic ore of the Great Cobar. Many difficulties have been encountered in carrying out the prognostications of the prospectus. Errors were made in the design of the new furnaces; the ore did not come up to expectations as to content; and a succession of labor troubles have intervened; H. C. Bellinger, late of Montana, is now manager. The report for the year ended June 30 shows that 271,827 tons of Great Cobar ore was raised and sent to the smelter; the production from the Cobar Gold mine was 45,778 tons; while 29,712 tons was raised from the Chesney mine. All the ore from the first two was sent to the smelter direct; 20,254 tons was sent direct from the Chesney, together with 1478 tons of concentrate obtained from the remaining 9730 tons. The total recovered was 6736 tons copper, 37,696 oz. gold, and 178,938 oz. silver. The average assays of the various ores are not given, but the general tenor can be ascertained from the figures for the reserves: at the Great Cobar, the reserve was estimated on June 30 at 1,813,087 tons, averaging 2.6% copper; at the Cobar Gold, 302,174 tons, averaging 1.7% copper and 9 dwt. gold; at the Chesney 623,286 tons, averaging 2.6% copper.

Development during the past year at Cobar Gold and Chesney has been entirely satisfactory. At the Great Cobar the 12th level showed a dislocation of the lodes, and diamond-drilling was undertaken with the object of finding the displaced northern orebody. Subsequent work on the 13th level has given much better results, for a cross-cut north has disclosed a body of ore averaging 3½% copper; the cross-cut has passed through 40 ft. and is still in ore. It is believed that this is the lost northern orebody. At the Chesney mine, the erection of the cencentrator was greatly delayed, and it only started work in April last. A Minerals Separation plant is to re-treat the tailing. As regards finance, the income from the production of metals was £635,252; the cost of mining and smelting was £457,222, and the London expenses £9413. The allowance for depreciation was £47,686; £43,488 was paid as interest on £724,800 debentures, and £43,161 has been written off underwriting commission. The balance of profit was £34,356, which was carried forward. It will thus be seen that no dividend has as yet been distributed on the £932,710 ordinary shares.

Information as to the operations at the Viloro dredging property at Oroville, California, is not as a rule published, and the contents of the report for the year ended October 31 are correspondingly interesting. The English company was formed in 1904 to acquire 200 acres in the Oroville district. Walter McDermott is chairman of the company, and T. H. Leggett is consulting engineer. The issued capital is £65,979. Dividends have been paid since the start, and up to October 31 last have totalled 73¾%. The report for the past year shows that 710,257 cu. yd. over 12½ acres was dredged, yielding gold worth $89,277, at a cost of $50,150, leaving a profit of $39,127. The yield per cubic yard was 12.57c. and the cost 6.06c. The amount treated was 164,588 cu. yd. less than during the previous year, the fall being due to the increase in the proportion of stiff clayey ground. Of the 200 acres, 130 has been worked, and of the remainder some are too lean to be profitable. Mr. Leggett estimates that the deposit will be exhausted in from 4 to 4½ years. W. H. James, the manager, reports that the overburden, varying from 8 to 20 ft. in depth, has proved troublesome to remove, and some of it has had to be broken by explosives. After the payment of administration expenses, a profit of £7188 was made, out of which £6597 has been paid as dividend, being at the rate of 10 per cent.

Tin mining in the Malay peninsula is usually associated with alluvial deposits. One of the few exceptions is the venture belonging to the Pahang Corporation, which owns extensive lode-property on the eastern side of the peninsula. Four years ago the property and plant got into a rather neglected condition, and a large amount of new capital was subscribed, to undertake special work recommended by William Frecheville, Reginald Pawle, and J. T. Marriner, the last named being the present manager. Profits were made in the year ended July 31, 1911, but were applied toward extinguishing an adverse balance. The report for the year ended July 31 last shows that the improvement has continued. The 50-stamp mill treated 102,797 long tons of ore, for a yield of 1125 tons of tin concentrate, as compared with 78,448 tons and 973 tons the year before.

The alluvial deposits are being worked by tributers, and the production was 115 tons as compared with 54. The income from the sale of concentrate was £148,755, and the profit, after payment of administration expenses, £45,341. Out of this, £4390 was paid as interest on debentures; £5000 was written off expense of raising capital, £5000 allowed for depreciation of plant, and £10,000 allowed for development and exploration. The year commenced with an adverse balance of £2521, and ended with a divisible profit of £18,879. Out of this, the whole of the arrears in the preference dividend, covering a period of 4 years and 1 month, has been paid, absorbing £15,577. J. T. Marriner, the manager, reports that the crushing and concentration plant has been greatly improved, so that its capacity has been increased and the cost of operation decreased. No less than 28,869 ft. of development work has been done, distributed over eight mines, along 5 miles. The ore sent to the mill came from seven of these properties, the largest amounts being provided by Willink's, Semeliang, Jeram Batang, Teague's, and Pollock's. The most important discovery was at Willink's, where the junction of two or more lodes has provided a large amount of rich ore; at the 500-ft. level the lode has been proved, so far, for 247 ft., averaging 9% cassiterite over a stoping width of 5 ft. As regards reserve, this is not easy to calculate, for so much of it consists of ore left by former owners; while the stamps are not as far ahead on the newly discovered ore.

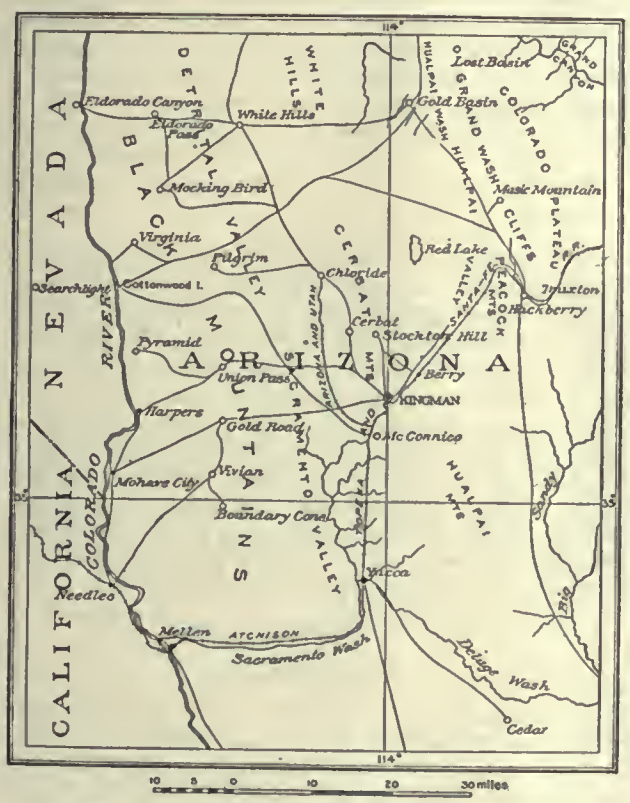
General Mining News

ARIZONA

During 1912 this state produced about 359,000,000 lb. of copper, and the value was increased by over $13,000,000 as compared with 1911, on account of the price of copper being 3.75c. per pound higher. The lead output was about 7,000,000 lb., a decrease of 32%; and the spelter output 8,500,000 lb., an increase of 89%. From the Golconda mine, at Union Basin, zinc ore and concentrate were shipped continuously, in September at the rate of 1200 tons per day.

Cochise County

At the Copper Queen smelter another reverberatory furnace and three McDougall roasters are to be constructed. About 900 men are employed. At the Sacramento shaft, foundations are being prepared for a new hoist, compressors, and boilers, and for change-houses at this and the Southwest shaft. During the past few weeks the Bisbee



WESTERN ARIZONA.

and Warren district mines have shipped nearly 6000 tons of ore per day to the smelters at Douglas.

The cold weather at Bisbee has been responsible for much trouble with ore freezing in cars and subsequent unloading at the Douglas smelters.

Maricopa County

The Arizona Copper Co. disputed its assessment for 1911 and refused to pay the $38,450 demanded in taxes. Suit was instituted, and the Superior Court upheld the assessment, judgment for the entire amount of the taxes, and costs, totaling $43,064, was given the plaintiff, the State of Arizona. The case has gone to the Supreme Court.

Mohave County

During 1912 the Tom Reed mill treated 43,994 tons of ore, and 10,462 tons of tailing, yielding $984,807 and $126,260, respectively, a total of $1,111,067. Dividends paid amounted to $596,637, the total to date being $1,155,169. The Frisco Gold Mines Co., working the Gold Crown group in the Union Pass district, treated 14,000 tons of ore, worth $115,000. The lode in this mine is of great width, and a larger plant is required. The Grand Gulch mine, in the Bently district, near the Colorado river, is shipping 150 tons of copper per month to Salt Lake, the past year's output being worth $127,750. The Union Basin Mining Co. shipped 11,800 tons of zinc ore and concentrate to the smelter at Bartlesville, Oklahoma, which returned $244,400 from zinc and $23,600 from gold and silver. Good ore is obtained down to 500 ft. depth. It is expected that the Gold Road Mines Co. will have produced $800,000 in 1912. The total production from all mines of the county was $2,571,818 during the past year.

Pima County

The Sasco smelter, at Silverbell, will be put in blast in the spring, and will treat over 400 tons of ore per day from the Christmas mine. The smelter has been overhauled, and an aerial tram, one mile long, has been erected at the mine.

A 100-ton capacity plant will be built, and probably a lead furnace to treat ores from Olive. Near this place, the Empire Zinc Co. is expected to erect works to treat zinc ores. The Lewisohns are prospecting their claims in the Rosewater district, Santa Rita mountains. Good sulphide ore has been cut in the North Star shaft at 100-ft. depth. Cross-cutting has been started at the 700-ft. level of the Esperanza, at Chesterfield. The Pontoc copper mines, 10 miles north of Tucson, are being unwatered prior to being prospected.

Yavapai County

At the Blue Bell mine the 900-ft. level is opening good ore. Pumps and ventilating apparatus are being placed. For the latter purpose, 4000 ft. of 15-in. galvanized iron will be used. A small mill is to be erected at the gold claims of Miller and Bawder, in the Santa Maria district. Lessees at the Crosby mine, in this district, treated 44 tons of ore worth $58 per ton. A shipment of 100 tons will be treated from the Fortune mine, in the Walker district.

Yuma County

The Arizona-Empire mine has 35 men working on the old road between Gold Hill and Parker. When this is finished the new road will be constructed and the Auto Delivery Co. will handle over 400 tons of ore per day with 21 auto-trucks. The ore at Gold Hill is quarried and averages $40 per ton.

CALIFORNIA

The latest statistics show that there are 1181 producing mines in California, of which 596 are deep mines, and 585 placers, including dredge, hydraulic, drift, and surface claims. Dredging seems to be the only form of placer work which is showing any marked advance. In deep-mining operations over 2,700,000 tons of ore is mined yearly in this state, by far the larger portion of this coming from the Mother Lode districts. The output of silicious ore has increased to some extent, and this usually averages from $4.65 to $5.25 per ton in gold and silver. Thirteen new stamp-mills, with 163 stamps, were added during 1912; also about 12 Huntington and Graupner mills, and 6 cyanide plants. The stamp-mills of California crush over 2,250,000 tons of ore per year, of which the Mother Lode counties contribute 1,400,000 tons; Amador county yielding 600,000 tons.

Amador County

The South Eureka mine, at Sutter Creek, will be shut down for some weeks owing to a cave-in in the main shaft at a depth of 30 ft., from where it collapsed for over 25 ft., jamming both skips. Nobody was hurt, and the miners escaped through connections with the Central Eureka mine. The 80-stamp mill of the South Eureka had already been shut down on account of the cold weather.

Kern County

Local reports state that the present year will be one of much activity at Randsburg. Electric power will be supplied by the Southern Sierras Power Co. within 30 days. The Consolidated Mines Co. is erecting a 5-stamp mill, and the mine is well opened to supply ore. A Braun rapid reduction mill, with a capacity of 3 tons in 10 hours, using 3 hp., is being installed on the property of the Gold Placer Co. This mill will be used to grind concentrate, so that scheelite can be separated from the gold by a Cummings separator. Four pumping plants at Inyokern were connected to the power plant of the Southern Sierras Power Co.

at San Bernardino. The pumps will require 1000 hp. to supply water for irrigating this district.

Placer County

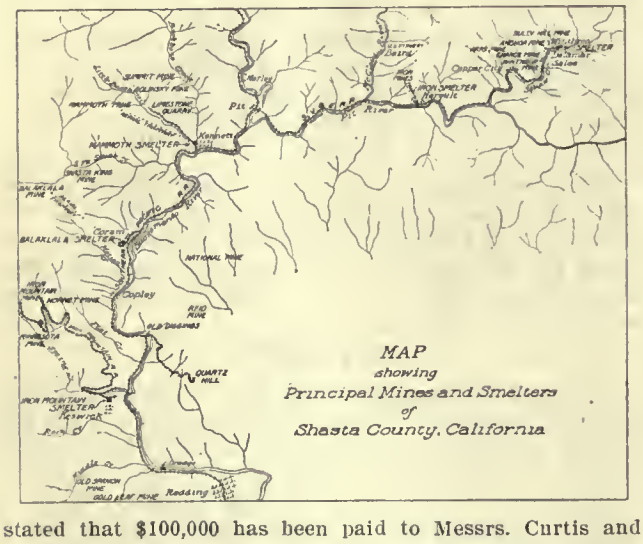
The Keystone drill, which was recently taken to Deer creek, below the Newtown district to test the gravel deposits, has been started. Three men from Alaska will operate the machine under W. Colley, of the Union Construction Co. of San Francisco. Holes will be put down to bedrock, and samples taken every foot, over a distance of 1000 ft. down the creek. If results average 20c. per yard a large dredge will be built.

Sacramento County

Since the Natomas Consolidated of California appointed E. K. Carnes as head of its horticultural work, plans have been made for establishment of a nursery, where all future stock will be raised. Ten acres of irrigated land near Nimbus has been selected. A hot-house has been rented temporarily in Sacramento until the land is ready, and 40,000 olive cuttings are to be planted. Eventually there will be three distinct nurseries—for olives, citrus, and ornamental trees.

Shasta County

(Special Correspondence.)—A syndicate of Seattle capitalists, headed by M. Thompson, has taken over 500 acres of gravel land near Igo, a few miles from Redding. It is



stated that $100,000 has been paid to Messrs. Curtis and Russell, the former owners. A bucket-elevator dredge will be built early in the present year. The same syndicate may acquire the Bryant tract of 1300 acres, in the same district. During the past year the Mammoth Copper Co. produced 28,000,000 lb. of copper from its Kennett smelter. The Noble Electric Steel Co. is increasing the capacity of its electric iron smelter at Heroult. The by-product plant is producing coke, tar, and other materials. Shasta county is estimated to have produced minerals worth $5,400,000 in 1912.

Redding, January 6.

The Mining Congress of Southern Oregon and Northern California will be held in the Armory Hall at Redding on May 14, 15, 16, and 17. A large attendance is expected, especially from Oregon. The last congress was held at Yreka, Siskiyou county.

COLORADO

Bullion valued at $38,194,003.76 was received at the Denver mint in 1912, an increase of $2,954,034.93 over the previous year. The bulk of this was received from Colorado, and small amounts were received from all the Rocky Mountain states.

Clear Creek County

(Special Correspondence.)—The production of this county for the past year is estimated as $1,491,949. The output from the south end of the county showed a 10% decrease, while the north end had an increase of 50%. Twenty-five men are employed at the New Era mine, at Freeland, and large shipments of ore and concentrate are being made.

Georgetown, January 7.

At the Capital-Central mine, on Griffith and Alpine mountains, a drift has been driven 400 ft. on the Aetna vein, which yields a large quantity of ore in the Capitol mine. The company owning the latter property is making plans for extensive development during the current year. Work at the Geneva, on Griffith mountain, is encouraging.

Lake County (Leadville)

The value of the ore mined at Leadville during 1912 averaged $24 per ton; and that treated at the Arkansas Valley plant, not including carbonate of zinc, averaged $15 per ton. The following table shows the production of the past year, as given by the *Carbonate Chronicle:*

	Tons.
Carbonate of lead ore	18,194
Oxidized iron ore	94,979
Sulphide ore	127,834
Zinc sulphide ore	38,619
Zinc carbonate ore	160,779
Silicious ore	25,049
Total	465,454
Gold, 55,492 oz., valued at	$1,147,019
Silver, 3,048,900 oz., valued at	1,856,171
Lead, 23,821,375 lb., valued at	1,065,768
Copper, 2,710,186 lb., valued at	440,405
Spelter, 98,136,060 lb., valued at	6,673,253
Total in 1912	$11,182,616
Total in 1911	8,227,017

The San Juan

This district of Dolores, La Plata, Ouray, San Juan, and San Miguel counties showed in 1912 a decrease of $1,000,000 in output of gold and an increase of 500,000 oz. of silver, 3,500,000 lb. of lead, and 700,000 lb. of copper. Zinc production was also 300,000 lb. less. During 1912, 20,590 tons of ore and concentrate was shipped from Ouray, and the county's output was: gold, $1,955,750; silver, $309,973; lead, $214,470; copper, $98,000; and zinc, $10,000; a total of $2,588,202. The Atlas 20-stamp mill yielded $250,000. At the Camp Bird a winze is being sunk 200 ft. to develop the ore-shoot cut last spring. The Wanakah mill was improved during the year.

IDAHO

Shoshone County

The suit of the Stewart Mining Co. and the Ontario Mining Co. was started at Wallace on January 6. The former company contends that the Ontario veins apex in the Senator Stewart claim, can be traced over their south endline, and that under the law of extra-lateral rights, the ore, valued at about $1,000,000, is theirs. W. Clancy, for the Stewart company, stated that the ore and country rock were similar in each claim. The case is still being heard. On Pine creek, the Nabob Mining Co. will develop the V group of 15 claims, by extending its 2300-ft. adit, and prospect for the upper veins of the V property. This will require 1500 ft. of driving, giving a depth of 1200 ft. on the Idaho vein. Connection with the power-line of the Washington Water Power Co. is being made for electric motors which are waiting at the property. The 1200-ft. adit of the Amy and Matchless claims on Pine creek is to be extended 2000 feet.

The estimated production of copper in this state in 1912 was 7,500,000 lb., which came principally from the Empire Copper Co. in Custer county and the Snowstorm mine in Shoshone county. The lead output was 279,000,000 lb. At Arco, the Wilbert Mining Co. operated a new mill which yielded 1,500,000 lb. The lead furnace at Hahn was burned in September, and a furnace at Clayton, in Custer county, was the only smelter operated in the state. Lead production represented 65% of the total metal output in 1912, or about $12,500,000.

The silver-lead mines of the Coeur d'Alene district paid over $3,000,000 in dividends in 1912. The Bunker Hill & Sullivan paid $850,000; Federal, $800,000; Hercules, $600,-

000; Hecla, $300,000; Success, zinc producer, $300,000; and Snowstorm, copper producer, $75,000.

MONTANA

This state retained second place among the copper-producing states, and in 1912 yielded 310,000,000 lb. Lead production was about the same as in the previous year, namely, 6,500,000 lb. There was a decrease of 41% in the spelter output to 25,520,000 pounds.

Granite County

(Special Correspondence.)—The Royal Basin Mining & Milling Co. recently made its first shipment of copper cathodes from its leaching and electrolytic precipitation plant at Maxville. The Granite-Bimetallic company, of Philipsburg, has completed a 500-ton cyanide plant to treat the tailing from the old mills. If the plant works as well as expected, the impounded tailing will supply it with a profitable grade for many years.

Philipsburg, January 13.

Missoula County

(Special Correspondence.)—The Carter district, near Superior, is active these days. The Chicago, Milwaukee & St. Paul railroad is constructing a spur for loading ore at Spring gulch. The King & Queen mine is hauling ore to bins at that point from its new 1500-ft. tramway terminal. Some work is going on at the Iron Mask, O. R. & N., and the Glen Metal mines.

Missoula, January 13.

Sanders County

(Special Correspondence.)—Butte interests have bonded a large tract of placer ground on Vermilion creek. The ground is to be proved by churn-drills and, if found satisfactory, dredges will probably be constructed.

Thompson, January 13.

Silverbow County

Out of 33 counties in Montana, 17 received $673,358 in taxes in 1912 from the Amalgamated Copper Co., Silverbow receiving $356,428, Deer Lodge $117,920, Missoula $51,298, Cascade $49,639, and Flathead, Ravalli, Lincoln, and Sanders, about $20,000 each. During the past year the 13 groups of mines at Butte produced 322,837,620 lb. of copper from 4,926,141 tons of ore. The year's work of the Amalgamated properties may be summarized as follows:

Men employed	13,941
Wages paid	$16,818,285
Fuel and power	4,724,662
Lumber and timber	3,107,461
Freight	5,859,154
Custom ore purchased	5,102,236
Supplies	2,688,080
Taxes, insurance, general	1,189,684
Total expenditure	$39,489,562
Dividends	$ 6,155,516

NEVADA

The lead production in 1912 was 13,000,000 lb., compared with 3,263,657 lb. in 1911, mines in the Pioche district of Lincoln county and the Yellow Pine district of Clark county furnishing the largest part of the output. The adjustment of litigation at Pioche resulted in increased ore production in that centre, along with the completion of a railroad spur to the Bullionville tailing dump. Zinc production was about 12,000,000 lb., an increase of 233% over 1911. The chief mine was the Yellow Pine, which is equipped with the only concentrating plant in the district.

Esmeralda County

Diamond-drills have never been used for prospecting at Goldfield, and the Consolidated company is to erect a complete plant, and drill from the lowest levels of the Clermont or Grizzly Bear workings.

Lincoln County

At the Prince Consolidated mine a 5-ft. vein, carrying higher metal content than in the upper levels, has been opened on the 400-ft. level. During the week ended December 28, 1847 tons of ore was shipped. There are 19,000 tons of ore broken in the stopes ready for extraction. The diamond-drill is 102 ft. below the 600-ft. level.

Mineral County

Eighteen miles from Schurz, the Queen Regent Merger Mines Co. is actively developing its estate of 700 acres. At the 300-ft. level an orebody 33 ft. wide has been opened. The formation lying above is a hematite of high quality in iron, and contains gold, silver, and copper worth $10 per ton. Work at the Queen Regent has been under way for about 18 months. The Gold Range M. M. & L. Co., at Douglass Camp, is erecting a stamp-mill, which should be finished early in January.

Storey County

At the Sierra Nevada there has been an improvement on the 2500-ft. level. The northeast drift was extended 23 ft. during the week ended January 4, the quartz being 3 ft. wide and worth $6.50 per ton. From the raise, 23 mine-cars of ore were saved, worth $25 and 20 cars worth $6.50 per ton. The Ophir and Consolidated Virginia companies continued enlarging the old McM. Ross winze and have driven to No. 12 level. The Crown Point shipped 773 tons to the Yellow Jacket mill. The gross tonnage from Crown Point, Belcher, and Yellow Jacket was 866 tons, valued at $6000. The Mexican mill treated 319 tons of ore worth $43.32 per ton, with 94% extraction, supplied by the 2300, 2400, and 2500-ft. levels. Four bars of bullion worth $4000 were shipped from the Ophir cyanide plant. Ice-jams on the Truckee river, which supplies the electric-power plant, caused a shortage of power for pumping at the C. & C. shaft, and the water rose within 2 in. of the motors, but in a short time the station was unwatered.

UTAH

Juab County

The Tintic district shipped approximately 500,000 tons of ore, worth $10,000,000, during 1912, an increase of 20% over the previous year.

Utah County

The annual report of the Iron Blossom company for the year ended December 1, 1912, shows the following details: No additional property was acquired during the year. A new electric hoisting plant was installed at No. 1 shaft and is ready for work. An immense quantity of ore has been opened, of better grade than before. At present a winze is being sunk at the contact of the dolomite at white lime in Spy Hollow. The main working adit caved from the 200-ft. level to the bins, and it was necessary to drive a new adit around this caved ground. The deepest ore yet opened is on the 700-ft. level of No. 1 workings, and indications are good for more ore. Development covered 7518 ft., making a total of 31,953 ft. to date.

Ore production:

No. 1 workings, tons	31,855
No. 3 workings, tons	27,612
Metal contents:	
Gold, ounces	12,712
Silver, ounces	1,939,844
Lead, pounds	4,731,504
Gross value	$1,499,136
Net value	$ 907,103
Total revenue	$1,136,445
Dividends paid	$ 400,000
Balance November 30, 1912	$ 332,807

The report gives full details of working costs in a commendable manner. During the week ended January 11 the new electric equipment at the No. 1 working of the Iron Blossom went into commission, this being the eighth mine at Tintic to adopt electric hoisting. The mine will now be developed below the 800-ft. level.

The 1350-ft. level of the Eagle & Blue Bell is showing good ore, and three carloads per day is shipped. At the Yankee mine development is being pushed on the 1800 and 2000-ft. levels.

WASHINGTON

Spokane County

(Special Correspondence.)—During the past year business done on the Spokane Stock Exchange amounted to 4,717,963 shares, valued at $2,116,355. The year was regarded by members as the most promising in history from the point of legitimate mining of the Pacific Northwest. February 19 to 21, inclusive, have been selected as dates for the second annual Northwest Mining Convention, to be held at Spokane. Invitations have been sent to the American Institute of Mining Engineers, electrical, chemical, civil, and mechanical engineers' organizations. On February 22 the visitors will be shown various engineering points of interest about the city, including the Monroe-street bridge, described in *Western Engineering*, October 1912; the work of the Washington Water Power Co. at Long Lake; and construction work of the Milwaukee and O. W. R. & N. Co. railroads.

Spokane, January 9.

CANADA

British Columbia

During the past year development work at the Nickel Plate mine included sinking the incline shaft 400 ft. and driving 300 ft. on four levels opened from it; start of sinking the Dickson incline to 3000 ft.; and diamond-drilling 3447 ft. The Windfall and four other claims were acquired for $150,000. The mill treated 70,239 tons of ore yielding $792,000, with about 94% extraction, the total output to date being $4,600,000.

Ontario

According to the Cobalt *Daily Nugget*, ore produced by mines in the district during 1912 amounted to 21,763 tons, yielding 30,500,000 oz. of silver bullion, valued at $18,500,000, bringing the total to date to $81,817,352, the gross value being $87,000,000. Dividends paid totaled $8,617,000, making $42,000,000 to date. Estimated ore reserves of Cobalt mines are valued at $30,000,000. The principal producers during the year were: Nipissing, 6,075,000 oz. of bullion and $1,800,000 in dividends; and La Rose, 3327 tons of ore, yielding 2,900,000 oz., worth $1,800,000. During December the Nipissing company produced 440,000 oz. of bullion from the Meyer vein. The high-grade mill treated 164 tons of ore and shipped 422,495 oz. of bullion.

Mines at Porcupine are resuming work, and some have as many men as before the strike was declared. About 70 cases under the Lemieux act, brought against employees of the Hollinger mine and others, were heard on January 6. A great deal of interest is attached to the outcome of the cases, which will be the first under the new act.

Quebec

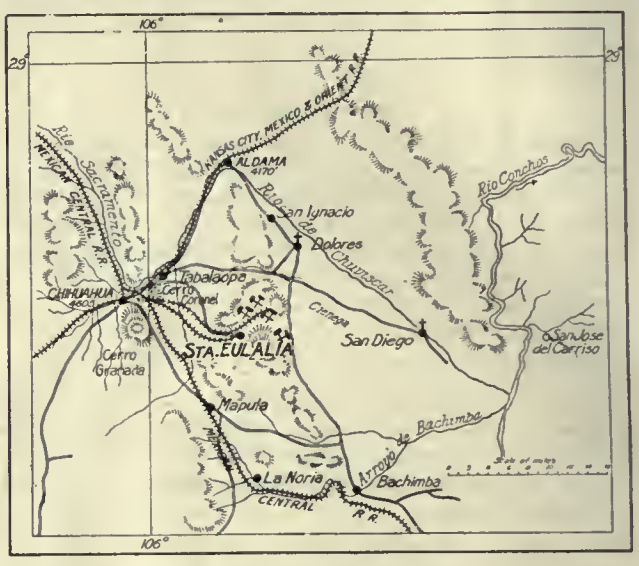
(Special Correspondence.)—The Champs d'Or Rigand Vandreuil, Ltd., has recently given an option on its entire property to A. C. Ludlum, president of the New York Engineering Co., for $1,500,000. This property is in Beauce county, in the province of Quebec, and comprises some 72,000 acres. It has been partly prospected, and was equipped with a hydraulicking plant which has operated successfully during the past season. This mine and its equipment was elaborately described and illustrated in the *Engineering & Mining Journal* of November 25, 1911. Mr. Ludlum now has engineers on the ground checking up former work and endeavoring to prove sufficient dredging area to warrant further equipment. It is his intention to equip the property with several large dredges if the present exploration work proves satisfactory.

Beauceville, January 10.

MEXICO

Chihuahua

(Special Correspondence.)—It is now generally quiet in the mountains. At the Chucheno there is a local guard and a detachment of volunteer troops near by. A new steam-electric plant is being erected and the mine is being re-equipped for this power. Extensive repairs are being made to the mill and the railroad. Auto trucks are running between the mine and the railroad as well as the freight wagons and pack-trains. The Sierra Mining Co. at Ocampo has most of the material for the new plant on the road to the mine, but no move toward erecting has been made. La Republica has definitely shut down. Yoquivo would like to operate, but being in a badly infested district, hardly dares to attempt it. Cusi has shut down until conditions improve. The continued interruptions of railroad traffic constitute the worst features of the present situation. It is nearly impossible to operate a property dependent on the railroad for supplies. The Americans have no quarrel with any party or faction here, no interest in the situation beyond the assurance that they be permitted to do business, and no desire to meddle. But the present tendency of Mexican sentiment seems to be to



PART OF CHIHUAHUA.

eliminate all Americans and American interests. Should they succeed in this, it may be imagined that they will notice a falling off in their revenues, both national and personal.

Chihuahua, January 3.

Guadalajara

The El Favor Mining Co. is shipping high-grade ore and is treating El Favor, Mololoa, and Mirador ores in its mill. A dividend of 1c. gold, amounting to $35,000, will be paid on January 30. The company has in the United States $47,379, and in ore and bullion in transit, etc., $67,341, making a total of $114,720.

American and French capitalists who had an option to purchase the Casados mines in the Hostotipaquillo district for ₱4,500,000 have decided not to complete the purchase owing to the present condition of Mexico. The Consolidated Mining Co., which owns the mines, will erect a 100-ton mill. During development the vein will be opened on the 500-ft. level and the shaft sunk to 600-ft. depth, while high-grade ore is shipped to the smelter.

Sonora

During December the Cananea Consolidated Copper Co. produced about 8,600,000 lb. of copper, while for the past year the total was 80,000,000 lb. At the 300-ft. level of the El Pilar mine, near Santa Cruz, good ore has been opened, and in January five cars of ore will be shipped to the Cananea smelter. Twenty-five men are employed, and a 50-ton mill will be erected in the spring. From the Josefina a carload of 22% copper ore has been shipped. This Santa Cruz district has been quiet for some time, but is again attracting attention. The new smelter of the Minneapolis Copper Co. at Cumpas is ready for work, and an annual production of 15,000,000 lb. of copper is expected. Through the port of Nogales in 1912 there were shipped to the United States 203 cars of ore and concentrate, and 79 cars of graphite.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

AL. FRANK is at Wallace, Idaho.

A. W. PAYNE has gone to Panama.

A. L. GHOLZ is now at Gila, Arizona.

E. A. BERUMNE is here from Mexico.

J. COWAN is here from Salt Lake City.

DONALD FERGUSON has gone to Guatemala.

BERNARD MACDONALD has returned to Guanajuato.

E. RAMMELMEYER is traveling in Italy and Germany.

P. N. MOORE has returned to St. Louis from the East.

WALTER M. BRODIE is now at 45 Broadway, New York.

C. C. GREENWOOD is on a visit to New York from Mexico.

THAYER LINDSLEY is in the West on professional business.

C. W. GRISWOLD and H. DE WERTTS are at the St. Francis.

P. S. SMITH has removed to San Francisco from Los Angeles.

J. BANERES DE ALZUGARAY is now at 115 Broadway, New York.

LOGAN BALLEW is with the Empire Copper Co. at Mackay, Idaho.

R. H. ANDERSON is now at 10 Avenida Cinco de Mayo, Mexico, D. F.

J. F. KEMP is returning from Florida, where he has been on a brief visit.

W. W. SHELBY is now with the Moctezuma Copper Co. at Nacozari, Sonora.

P. A. WICKHAM was in San Francisco this week, but is returning to Mexico.

OSCAR LACHMUND has been appointed general manager for the British Columbia Copper Co., Ltd.

ALEX FYFE is now metallurgist for the Cia. Minera y Exploradora de Ventanas, S. A., at Ventanas, Durango.

FRED SMITH, superintendent of the Mohawk and Wolverine mines, has resigned on account of age and ill health.

R. B. BRINSMADE recently returned to Puebla, Mexico, after a two weeks' visit to the northern part of the state of Mexico.

WILLIAM WRAITH was recently presented with a chest of silver by the employees and staff of the Washoe smelter at Anaconda.

J. E. SPURR, EDMUND JUESSEN, S. H. BRADY, and JAFET LINDEBERG were among those who last week visited Rochester, the new Nevada mining district.

GEORGE T. COFFEY, superintendent of hydraulic operations for the Yukon Gold Co., Dawson, Canada, has recently returned to San Francisco and will remain for about three months.

HENRY H. ARMSTEAD is in Guanajuato, Mexico, making an inspection of the properties of the Coimena Mining Corporation, and the Montana & Mexico Mining Co., and will visit the properties of the Mexican United Co. in Tepic and Jalisco before returning to New York.

Obituary

SAMUEL N. KNIGHT died at Sutter Creek, California, January 13, at the age of 76. He was born at Gardner, Maine, and came to Sutter Creek in 1863, where he bought an interest in the local foundry and engaged in the manufacture of milling and mining machinery. A bridge-builder by profession, he was also the inventor of the Knight waterwheel, and in other ways exhibited a high degree of mechanical skill. A public-spirited citizen of the best type, he exerted a remarkable influence over young people, so that the education received by the young men he trained in his shops was moral as well as technical. Though he leaves no family, many mourn his 'crossing the divide.'

In North America, according to the United States Geological Survey, the lowest point is in Death Valley, California, 276 ft. below sea-level; but this is a slight depression compared to the basin of the Dead Sea, in Palestine, Asia, where the lowest dry-land point is 1290 ft. below sea-level. In Africa the lowest point is in the Desert of Sahara, about 150 ft. below sea-level, but the Sahara as a whole is not below sea-level, although until recently the greater part of it was supposed to be. In Europe the lowest point at present known is on the shores of the Caspian Sea, 86 ft. below sea-level. In Australia the lowest point is at Lake Torrens, about 25 ft. below sea-level.

Copper Review for December

By Misha E. Appelbaum

The increase during the month of December in the visible supply of copper in the United States, 19,000,000 lb., was much larger than anyone anticipated, and the surplus of copper has now again reached a comfortable figure. It is useless to try to contradict the fact that even with good business, the best that can be hoped from now on is that deliveries and production will about equal each other, and as a result producers cannot expect any increase in the price of copper or look for any material betterment. The question to decide, however, is whether the enormous deliveries of 1912 can be duplicated in 1913. The production will be fully as large in 1913 as in 1912, and if the deliveries are as large, it will mean that the present price of copper can hold. There is too much uncertainty surrounding the business world to enable one to say that business during the present year will be as good as last year, and for that reason I cannot look for any higher prices. At the same time the intrinsic conditions of the business world are sound enough so as to make one hope against any serious decline. In fact, these arguments can be applied with perfect safety to almost all the metals.

The Petroleum Industry in 1912

According to David T. Day, of the U. S. Geological Survey, the Eastern petroleum fields declined in production, because it was impossible to keep up the great output of 1911 without large additional discoveries of new pools in the older fields. The Eastern decline was, however, offset by the increase in California, where the San Joaquin Valley fields (Midway, McKittrick, Maricopa, etc.) are still at the height of the gusher stage.

Production of Petroleum in the United States in 1911 and Estimated Production for 1912, in barrels of 42 gallons.

State.	1911.	1912.
California	81,134,391	87,000,000
Oklahoma	56,069,637	52,000,000
Illinois	31,317,038	28,000,000
Louisiana	10,720,420	10,000,000
West Virginia	9,795,464	11,800,000
Texas	9,526,474	10,500,000
Ohio	8,817,112	8,500,000
Pennsylvania	8,248,158	8,000,000
Indiana	1,695,289	1,200,000
Kansas	1,278,819	1,300,000
New York	952,515	700,000
Kentucky	472,458	500,000
Colorado	226,926	200,000
Other states	194,690	500,000
	220,449,391	220,200,000

The total value of the product increased markedly, being about $150,000,000 compared with $134,144,752 in 1911.

In all the fields except those of California and the Gulf there was a heavy drain on stocks during the year, so that from a total of 81,789,390 bbl. (over a half year's output) on January 1, the stock declined to 69,000,000 bbl. at the end of the year. This drain reflects the increased capacity of the refining plants of the United States, the greatly increased exports, and a gradual change in the general condition of the industry.

The general decline in production, except in California, would doubtless have been much greater but for the effort to apply laws of supply and demand by increases in prices. Prices advanced so greatly during the year as to stimulate drilling, even in the old New York and Pennsylvania pools, and so checked the decline. Formerly this plan has not been so successful. In the Mid-Continent field also it checked the decline, so that the product will come within 4,000,000 bbl. of the maximum output (in 1910).

Quicksilver in 1912

Preliminary figures collected by H. D. McCaskey, of the United States Geological Survey, from the individual producers show that the domestic production of quicksilver in 1912 was 25,147 flasks of 75 lb. each, valued at the average San Francisco domestic price for the year, $42.04, at $1,057,180. A comparison of these figures with the final published Survey figures for 1911 and 1910 shows a gain over the output of 1911 of 3891 flasks and over that of 1910 of 4546 flasks. Twenty mines were reported as producing in 1912, of which 16 were in California, against 22 producers in 1911, of which 19 were in California. The production for 1912 showed a larger increase than was estimated in our issue of January 4, and generally expected, but it is not thought that a correspondingly large increase can be looked for in 1913.

The production of quicksilver in California in 1912 was 20,613 flasks, valued at $866,571, against an output of 18,860 flasks, valued at $867,749, in 1911. It was the largest production since that of 24,635 flasks in 1905. The increase was due mainly to the yield of the New Guadalupe mine, in Santa Clara county, but also to increased output from several other mines. In San Benito county the New Idria mines yielded slightly less than in 1911, but remained the largest producers in America and are to be credited with nearly half the entire output of California.

No production of quicksilver was reported from Arizona, Oregon, Utah, or Washington in either 1912 or 1911. In Nevada there was a largely increased output from the Mercury mines, near the old Ione district, in Nye county, where a modern Scott furnace has been in operation, and a small production was reported from the Telluride prospect, near Beatty. Considerable prospecting and development of quicksilver deposits have been reported from Bare mountain and other localities near Beatty, and in other districts in Nevada, and the production from this state may further increase in 1913. The Shoshone mines, near Ione, were not producers in 1912. In Texas, the Chisos mine at Terlingua, Brewster county, continued to make a considerable production. The combined output of quicksilver in Nevada and Texas for 1912 was 4534 flasks, valued at $190,609, against 2396 flasks, valued at $110,240, in 1911.

The market was fairly good for quicksilver in 1912. The imports were again in considerable excess over the exports and the demand was generally strong and apparently somewhat larger than the domestic supply. Prices began the year at $42.50 per flask for San Francisco domestic as the January average, rose to $44.40 for the March average, and thereafter gradually declined to the December average of $40.50—the average San Francisco domestic price for the year being taken at $42.04. The corresponding price in 1911 was $46.01. Exports of quicksilver from the United States in 1912 are estimated, from the records of the Bureau of Foreign and Domestic Commerce of the Department of Commerce and Labor, at 24,000 lb., valued at $14,000. In 1911 the exports were 21,841 lb., valued at $13,995.

Production of Iron Ore in 1912

Preliminary estimates of iron ore mined in 1912, based on the quantity mined during the first eleven months of the year plus estimates for the month of December, were received by the United States Geological Survey from 26 of the largest iron-mining companies in the United States at the close of the year. As the combined output of these 26 companies represents more than 80% of the iron ore mined in the United States, it is considered that the condition of the industry is fairly well gauged by their production, especially as both the Lake Superior and the Birmingham districts are well represented.

The average increase in the production of iron ore by these representative companies was 26.6%. Certain companies showed a decided decrease in production and others reported as much as 80% increase, but the outputs of such companies as reported abnormal production are not sufficiently great to largely affect the grand totals.

From the returns received it is estimated by E. F. Burchard, of the Geological Survey, that the total quantity of iron ore mined in the United States in 1912 was between 54,500,000 and 57,500,000 long tons. This quantity represents an increase of between 25 and 32% compared with the production in 1911, which aggregated 43,550,633 tons. It is therefore possible that the high record of iron ore output attained in 1910, 56,889,734 long tons, may be slightly exceeded, although the returns received thus far, which are only approximate figures, are not quite sufficient to justify a definite comparison with the figures for 1910. Red and specular hematite constituted about 90% of the output, most of the remaining 10% being divided about equally between limonite, or brown ore, and magnetite, with a very small quantity of siderite, or spathic ore.

In the Lake Superior district the production of iron ore apparently increased in slightly greater proportion than the average for the country at large, the total shipments having increased from 32,783,163 long tons in 1911 to nearly 48,750,000 tons in 1912. Production in the Birmingham district, Alabama, was largely increased in 1912, especially through the large output of the Red Mountain group of Clinton hematite mines operated by the Tennessee C. I. & R. Co. The production in Tennessee, North Carolina, and Virginia apparently has not greatly increased, if at all, above that of 1911.

Tungsten Production in 1912

The quantity of tungsten ore mined and marketed in the United States during 1912, according to preliminary figures collected by Frank L. Hess, of the United States Geological Survey, was equivalent to about 1290 tons carrying 60% of tungsten trioxide and was valued at $492,000, besides which a smaller quantity was mined but not marketed. This is an increase over the output of 1911, which was equivalent to 1139 tons of 60% ore and was valued at $407,985. The average price paid per unit (the unit is 1% of a short ton, or 20 lb., of tungsten trioxide) was about $6.35 in 1912, compared with $4.89 in 1911, but the extreme variation seems to have been less in 1912 than in the previous year. Although higher than in 1911, the price paid was unsatisfactory to the miner. It ranged from $5.80 to $7.25 per unit for ore running 60% or more of tungsten trioxide, and $8 was being quoted at the close of the year. Probably more concentrate was sold at $6 than at any other figure.

As usual, the largest production from any single district was made from the unique ferberite deposits of Boulder county, Colorado. About 1200 tons of ore of various grades was shipped out, equivalent to 775 tons of 60% ore. The Primos M. & M. Co. and the Wolf Tongue M. Co. are the largest producers in the district. The Wolf Tongue M. Co., which works its properties by a leasing system, introduced an important new feature during the year by furnishing electric hoists free to its lessees, and the company also pays a portion of the cost for sinking each shaft. The lessee pays for the cost of electric current used. It seems probable that this innovation will lead to an increase in production from the properties during 1912, unless the price should drop seriously.

In California the Atolia M. Co., which controls the Atolia field, at the north edge of San Bernardino county, increased the production of its remarkably pure scheelite over that of 1911 and was the largest individual producer in the United States. A small quantity of scheelite was also taken out in the Stringer district, a few miles north and west of Atolia. A discovery of scheelite was reported from the west side of the Rand mountains, but no ore was sold. A few tons of mixed wolframite and scheelite was shipped from the vicinity of Nipton, in the east end of San Bernardino county.

In Arizona a few tons of hübnerite concentrate was shipped from the dry placers and some ore from the veins near Dragoon; hübnerite ore was shipped from Arivaca to Denver, for concentration; and some scheelite concentrate was shipped from Oracle, where scheelite is associated with gold and silver ores. Small shipments of hübnerite were made from Osceola and Round Mountain, Nevada, and Patterson Creek, Idaho. A small quantity of hübnerite was concentrated at Loon Lake, Washington, but none was shipped. One small shipment of wolframite was made from Lordsburg, New Mexico.

Uranium and Vanadium Mining in 1912

The figures for the production of uranium and vanadium ores during 1912 have not been satisfactorily reported to the United States Geological Survey, and the output has therefore been partly estimated by Frank L. Hess from various data in his possession. Shipment of uranium and vanadium ores during 1912 has been in the hands of about a dozen persons and firms, and as in previous years the ores have come mostly from southwestern Colorado, with a smaller production from southeastern Utah, between the San Rafael swell and the Colorado line.

The production of uranium appears from preliminary estimates to have been equivalent to a little less than 26 short tons of uranium oxide, or approximately 22 tons of metallic uranium, a slight increase over 1911, when the production was equal to about 25 tons of uranium oxide, or 21.2 tons of the metal. The vanadium output of 1912 seems to have been equivalent to a little less than 300 tons of metallic vanadium, a somewhat larger quantity than that of 1911. The uranium-bearing ores were all carnotite, a variable compound of uranium and vanadium with other elements, found with several vanadium minerals in sandstones of Jurassic-Triassic age in the high plateau region of Utah and Colorado. So far the richest and largest deposits found are in Montrose county, Colorado, in Paradox valley, Long Park, the McIntyre district, and adjacent territory, extending into San Miguel, Dolores, and Mesa counties. In Utah the deposits mined are in Emery and Grand counties. Deposits which were unproductive during the year occur in Rio Blanco, Routt, and Moffat counties, Colorado, and in Uinta and San Juan counties, Utah. The percentage of uranium oxide (U_3O_8) in the ore varied from 0.5 to 6.32. The percentage of vanadium oxide (V_2O_5) in the same ores varied from 1.42 to 13.63. The relation between the uranium oxide and the vanadium oxide was likewise variable. At one extreme was an ore that carried 8.15% V_2O_5 and 1.54% U_3O_8; at the other extreme was an ore that carried 5.79% V_2O_5 and 6.32% U_3O_8. Of the more widely known uranium mineral, pitchblende or uranite, a few hundred pounds was mined near Central City, Gilpin county, Colorado. It was all sold as specimens and to laboratories, probably for experimental work. A few pounds partly altered to gummite and other secondary minerals was found in mining mica near Penland, North Carolina.

The larger part of the vanadium ore produced was a sage-green sandstone colored by the vanadium-bearing mica, roscoelite. It was mined near Newmire, San Miguel county, Colorado, and the vanadium was obtained in the form of iron vanadate at the local reduction plant of the Primos Chemical Co. The iron vanadate is shipped East to be smelted into ferrovanadium. Vanadium ores, probably volborthite and calcivolborthite, were prospected on Pass creek near Malachite, Huerfano county, and southeast of Silver Cliff, Custer county, Colorado, but no production was made. No vanadinite is known to have been mined for vanadium in this country during the year.

Prices varied much, but 25 to 30c. per pound for the contained vanadium oxide and $1.30 to $1.50 for the contained uranium oxide where it exceeds 2½% seem to have been the rule. The prices were considered too low by some producers, and their ore was stored awaiting a rise. Most of the ore goes to England and Germany and is said to be wanted especially for the radium content. The price of metallic vanadium was much below former years and from $4 or $5 per pound it fell to $2.50 and $2 for the contained vanadium or ferrovanadium, undoubtedly owing to competition between American firms. The imports of roasted sulphide ore from Peru were large and the production of ferrovanadium was probably the largest to date.

Book Reviews

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

CONCENTRATING ORES BY FLOTATION. By T. J. Hoover. 221 pp., ill. *The Mining Magazine*, London, 1912. For sale by the *Mining and Scientific Press*. Price $3.75.

A more timely book than this volume of Mr. Hoover's is difficult to imagine. After years of experiment and, unfortunately, litigation, chiefly in foreign countries, flotation processes have been brought to a point where rapid application upon a working scale is now the order of the day, and important plants in North America have already been constructed or are planned. Every well informed engineer is eager to become possessed of accurate information concerning the principles of flotation without undergoing the enormous amount of mental labor performed by the comparatively small group of men, among whom Mr. Hoover ranks to the fore, who have brought these processes to their present degree of perfection. The tremendous importance of flotation in ore-dressing practice lies in the fact that it utilizes common but unfamiliar phenomena for the successful treatment of material unamenable to older methods. This is so important as to deserve some elaboration.

In ordinary wet concentration of ores (omitting minor methods) the vital factor is the difference in specific gravity of the minerals treated, so that particles of equal volume have different mass. By the skilful use of water currents this may be employed to separate minerals from each other. The forces involved in this are large and are modified by other lesser forces that produce little effect on particles of moderate size. As the size of the particle decreases the gravitational force decreases, since it is dependent upon the mass, which varies as the cube of the diameter. The minor forces are dependent upon the surface area of the particle, which rapidly increases in proportion as the diameter increases. Thus, if a cube of 4000 sq. in. surface is broken into 40-mesh particles, the total surface area of the particles is over 30,000,000 sq. in.; in other words, the importance of the minor forces, as compared to the major force of gravitation, has been multiplied nearly 9000 times. If the material is very finely divided it will not sink, even in still water, except after the lapse of a long time. Thus ordinary methods of wet concentration break down when applied to finely divided material; they are not adapted to slime concentration. But milling practice has constantly tended toward the treatment of finer and finer material, since lump ore is comparatively difficult to procure, while deposits in which small amounts of valuable mineral occur are relatively abundant. And just as with the growing necessity for abundant power, rapid transportation, and easy communication, inventors devised the steam-engine, locomotive, and telegraph, so with the need of new methods of ore concentration the principles of flotation have been developed.

Like the development of electrical apparatus, flotation is partly dependent upon common phenomena of everyday life, of which the ordinary man takes no notice because he makes no use of them, and partly based upon new relations which have until now escaped observation because their perception was impossible without well directed experiment. The basal features are not at all obscure, and a Western 'school-marm,' in washing greasy sample-bags in hot soapy water, observed the essential factors that govern the modern processes. From that observation, nearly thirty years ago, to H. L. Sulman's more recent studies of the hysteresis of the contact angle between liquids and solids is not so far a cry as might appear. Drops of water sprinkled on a dusty floor similarly afford opportunity for the observation of some of the most significant phenomena of flotation, to one who is able to perceive their significance. The obscurity in which flotation methods have been enveloped is chiefly due to the desire of investigators to secure for themselves all the commercial advantages which might accrue from them. The fact that no contribution to the advancement of this important new development in the art of ore dressing has come from any of our technical schools or universities, with the single exception of the important work of K. A. Mickle, is a severe commentary upon the usefulness of the work which is being carried on under their auspices.

Returning to the book itself, which obviously demands some space in a book review, it should first be noted that Mr. Hoover is among those best entitled to speak with authority concerning flotation, having been intimately associated with much of the most important work done and having made important personal contributions to the art. He has been able, therefore, to prepare a detailed study in simple language and has included in this volume all that any ordinary engineer will need or care to know concerning flotation. The history of the experimental work which has led up to the present state of the art, and the litigation between patentees are admirably summarized, since in the present unfortunate state of our patent laws, litigation concerning patents is as much the affair of the operators as the patentees. The theory of flotation is briefly discussed in an easily understandable way, though the section on commercial effectiveness, page 59, is rather obscure. On the other hand, on the following page, the desire for simplicity leads to the use of a misleading comparison between the coagulation of soap solution by acid and the coagulation of sulphides by oil. The former is, of course, a chemical phenomenon and the latter a physical one; whatever resemblance exists being purely superficial. Mr. Hoover mentions that H. L. Sulman and H. F. K. Picard have in preparation an elaborate study of the theory of flotation. While this will be welcomed by investigators, Mr. Hoover's briefer exposition of the matter will meet the needs of most engineers. A chapter devoted to tests by flotation on ores will be one of the most useful features of the book. Five following chapters are devoted to detailed descriptions of the various processes. Considering how intimately Mr. Hoover has been engaged in the development of the art it is remarkable that he does not exhibit more bias in his comment. Not unnaturally, his own work receives full consideration, and opinions will differ as to the justice of the importance assigned to the work of others; thus Potter is perhaps somewhat slighted, and Hyde's work overemphasized. The operator is, however, concerned less with degrees of credit than with commercial returns. A chapter is devoted to the consideration of the economical factors of flotation methods, that is of corresponding importance. A full bibliography concludes the book, and will be of great assistance to those engaged in experimental work along these lines. It is not too much to say that Mr. Hoover has given us the most notable book of the year in this condensed summary of a new art with which every mining engineer should possess some degree of familiarity.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

GYRATORY CRUSHERS totaling 19 are at work at the Homestake mine and mills; and storage-bins hold 6200 tons of ore.

OIL STOCKS in the United States on January 1, 1912, were 81,789,390 bbl., while at the end of the year they were reduced to 69,000,000 bbl., according to the U. S. Geological Survey.

'STRAIN-BURST' is a term proposed to be used on the Rand instead of air-blast, which refers to the sudden dislocation of rock in many mines. In the Champion Reef mine, India, 'bursts of rock' are still common, and the damage done by them often leads to considerable expense in repairing the workings affected. It is stated that records show a substantial decrease in their number.

EROSION of the land surface in the United States is of enormous extent, and 270,000,000 tons of dissolved matter and 513,000,000 tons of suspended matter are transported to tidewater every year by the various streams. If this erosive action had been concentrated upon the Isthmus of Panama at the time of American occupation, it would have excavated the prism for an 85-ft. sea-level canal in about 73 days.

STEAM-DRIVEN AUXILIARIES in a power-plant are more satisfactory than electric. In steam pumps the consumption is high, 60 to 100 lb. per b-hp.-hr., but by exhausting into a feed-water heater, the latent heat is regained. With electric drive, the power is taken from the thermally inefficient main engine and though only one-third or one-fourth as much steam will then be required, the latent heat will be lost. There is also a common feeling that steam is more dependable.

PYRITE was mined in the Urals to a greater extent than ever in 1912, but owing to the great distances in Russia this has not affected the situation in the western provinces, where foreign pyrite supplies numerous chemical works. A new industry in the manufacture of fertilizers and superphosphates is being built up in the Urals. Despite the activity of the copper mines in Russia, the sulphur fumes are still wasted. The copper companies are too busy making metal to worry about the sulphur.

STATISTICS recently collected by the Bureau of Mines show that about one-third of the fatal accidents and one-fourth of the non-fatal ones in the past seven years have been due to the steep inclination of the coal beds. Because of the steep inclination of the coal beds one man cannot visit nearly so many working places in a given time as he can in a mine where the beds are flat. The result is that working places are not visited with sufficient frequency by the mine officials. This fact, coupled with the readiness of the average Washington coal miner to 'take a chance' to save a little time or work, is responsible for many of the accidents.

MORTAR-BOXES of steam stamps at the Lake Superior copper mills are fitted with a device for removing mass copper of fist size and smaller, which may have escaped the eye of the feeder, or may have been liberated from the rock by the stamp. This consists of a pipe connection with the mortar-box, through which water is forced into the mortar under such pressure that the copper can pass down the pipe against the stream, while the lighter rock is restrained and kept in the mortar for further crushing. These hydraulic mortar-cleaning devices are of great assistance in maintaining the capacity of the stamp by removing metal which it would be useless to try to crush, and by rendering it unnecessary to operate the mortar for periodical cleaning by hand.

MINERS may cut from locations upon public land (excluding land in the National Forests) without asking for a permit, all the timber necessary in the mining and development operations; but as he is only an occupant operating under a license, although owning the mineral under his possessory right, he does not own the timber so as to be able to make whatever disposition of it he wishes, until the issuance of the receiver's receipt in the process of patenting the claim. Up to the issuance of the receiver's receipt, he cannot sell any timber from his claim; and it appears that he cannot lawfully cut timber from his locations, without a permit, for other purposes than that connected with their development and the milling, smelting, or reduction of his ores.

SECTIONALIZED mortar-boxes made for mountain transport are seldom satisfactory, unless the ore to be milled in them is exceptionally friable and a high duty can be obtained with a light stamp. So far no attempt has been made to sectionalize the Nissen stamp, but 2-stamp batteries are under construction for one of the latest Mexican mills, situated where transportation is difficult. Among other types of crushing machines which are capable of being sectionalized are the smaller sizes of rolls and the ordinary or No. 5 Krupp ball-mill. The use of rolls in mountain districts is not altogether to be recommended, other than in connection with small properties. The wearing parts make bad mule loads, and, in consequence, the repair cost is high. In the sectionalized ball-mill the liner plates are made so as to form good mule loads, and the machines, when erected, can be worked as efficiently as the ordinary mill. A further advantage with the ball-mill lies in the fact that in the event of a shortage in the supply of steel balls, any scrap iron or steel of similar size and shape can be used, the shanks of old battery shoes making excellent temporary substitutes for steel balls. By an increase, or decrease, in the load of steel, the output from a ball-mill can be raised above, or lowered below the normal amount without altering the screening. There is, however, a limit to the overloading, as the perforated grinding plates have only a certain delivery to the coarse screens.

PLUNGER PUMPS elevating mill pulp often give trouble through emptying the sump, and then refuse to pick up their load again, when the sump fills up. This is overcome at several mills in Kalgoorlie by means of a self-priming apparatus. The duplex Cornish pump, with plungers 10 by 48 in. lifts pulp from the stamps to a diaphragm-cone, and also from the tube-mill and the grinding pan. The pump is provided with counterbalances. The object of this gear is to constantly keep the pulp within an inch or so of the bottom of the suction pipe, which is done in the following manner: the counterbalance, 2 by 3 ft., is filled with water. A 1-in. pipe is connected with the pump barrel, as close to the stuffing-box as possible, and is led to the counterbalance. On the up-stroke of the plunger, pulp is drawn up the pump suction pipe, and also from the counterbalance. On the down-stroke, the pulp is forced through the pump delivery column, and also into the counterbalance, only a small quantity surges to and fro between the pump-barrel and the counterbalance. When the pump is on the point of forking, the amount of pulp necessary to prevent it from doing so is drawn from the counterbalance, and is returned on the down-stroke. A cock may be fitted to the pipe leading from the pump-barrel to the counterbalance, so as to adjust the quantity of pulp surging to and fro. The advantages of this balancing method are: that the pump being always nearly in fork, the sump is practically empty; no intermittent choking with sand occurs; the delivery through the rising column is constant; and the pump pit then provides the necessary storage for drainage from the stamps and grinding or other plant, when the mill is stopped for any purpose. There is, of course, a slight loss in the volumetric efficiency of the pump; but, on the other hand, a higher plunger speed can be adopted, since the use of the counterbalance eliminates air-lock shocks. The loss of power caused by the surging of the pulp from barrel to counterbalance is small.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

ASSESSMENT WORK—EVIDENCE OF PERFORMANCE

An affidavit that plaintiff has in his possession the affidavits of three men to the effect that certain mining assessment work was not done for a certain year is not evidence of such fact.

Anderson *v.* Robinson. (Oregon) 127 Pacific, 546. November 12, 1912.

SURFACE OWNERSHIP AND MINERAL RIGHTS DISTINCT

The surface ownership of land may be in one person and the ownership of the minerals in another, so that the owner of land may convey the surface to one and the minerals to another, or reserve them to himself, or vice versa.

Ball *v.* Clark, (Kentucky) 150 Southwestern, 359. November 1, 1912.

OIL LEASE—CANCELLATION DENIED

Where an oil lease contained an implied covenant that the lessee would drill as many wells as were necessary to develop the property to the mutual benefit of both lessor and lessee, and the lessee drills only three wells, in the absence of allegations definitely showing that this number was insufficient or that the lessor was fraudulently draining the territory through wells drilled on adjacent land, a bill in equity for cancellation of the lease was dismissed.

Hall *v.* South Penn. Oil Co., (West Virginia) 76 Southeastern, 124. October 8, 1912.

REPAYMENT OF PURCHASE MONEY DENIED

Where an applicant for patent for a mining claim, after due notice that charges have been filed by an officer of the Government affecting the validity of the claim, fails to make any denial of the charges or to apply for a hearing and the application is thereupon rejected, he is not entitled, in the absence of a showing, that the default and judgment were taken as the result of mistake, surprise, or excusable neglect on his part, to repayment of the purchase moneys paid in connection with the application for patent.

Jefferson Lime Co., 41 Land Decisions, 288. August 19, 1912.

MINERAL LAND WITHIN RAILROAD GRANT

The discovery of the mineral character of the land within the primary limits of the grant made to the Southern Pacific Railroad Co. by the Act of July 27, 1866, at any time before the issue of patent will defeat the grant. Deposits of petroleum are mineral within the meaning of that Act. The mineral character of a tract of land within such a grant is prima facie established by its classification as oil-bearing land; but the company is entitled, upon proper notice and showing to a hearing to show error in the classification.

Southern Pacific Railroad Co., 41 Land Decisions, 264. July 11, 1912.

RELATION OF PATENT TO DATE OF FINAL RECEIPT

Where two of the four locators of a mining claim, after doing all the assessment work thereon for two years, took steps to forfeit the rights of their co-owners by notice, and thereafter applied for and obtained a patent in their own names, but after obtaining final receipt from the land office and before issuance of the patent conveyed the claim to third parties by deed, it was held that the patent when issued became operative by relation from the date of final receipt, and that their conveyance subsequent to that date divested them of all interest. Hence the forfeited co-owners could not erect a trust on the title of the locators nor would any conveyance by the locators to such co-owners subsequent to the issuance of patent vest any title whatever in the co-owners. Suit was also barred by laches.

Cassidy *v.* Silver King Coalition Mines Co., (Utah) 199 Federal, 100. August 15, 1912.

Modern Steam Stamps

The Nordberg type of steam stamp is now being used in the newer mills of the Lake Superior region, according to *Metallurgical and Chemical Engineering*. These stamps are of the steeple-compound type, with cylinders mounted on round column framing of rigid construction, and standard mortar with solid anvil blocks below. The low-pressure cylinder is placed above the high-pressure, and connected thereto by means of a distance piece of cast iron, giving access to the stuffing box. The high-pressure cylinder is also mounted on a distance piece, for the same purpose. The cylinder heads are so constructed that they will break out in case they are struck by the pistons, thus saving the balance of the machine from destruction in case of such accident. The low-pressure cylinder is provided with Corliss valves at top end only, for the downward stroke. The high-pressure cylinder has valves at both ends, the lower valves controlling steam admission and exhaust below the high-pressure piston for the purpose of raising the stamp shaft.

The valve gear is of Nordberg patent type with double disc differential motion. There are six eccentrics, one for each valve, the eccentrics driving the lower high-pressure valves and the low-pressure valves being mounted on the pulley shaft, while those driving the upper high-pressure valves are mounted on the secondary shaft. Graduating dials are provided for each eccentric, indicating the petition of their central lines relatively to each other. By this arrangement it is expected to get a higher economy in steam than with the old arrangement now used, this economy resulting mostly from a free exhaust at the bottom, whereby the vacuum carried by the condensers can be more fully realized on the stamp piston than with the arrangement where only one valve is used to control the distribution of steam at the lower end of the cylinder. It is also plain that by this arrangement a more delicate adjustment of the steam distribution to both ends of the stamp can be obtained than by a two-valve arrangement.

The bearings on which the secondary shaft is mounted are fitted to a slide wherein they can be adjusted in such a manner that the ratio between the fast and slow motion can be varied between wide limits. The fly-wheel on valve-gear shaft is turned on rim edges, and adapted for belt drive. No loose pulley is used in connection with this arrangement, but it is expected that a tightener will be employed to stop and start the valve motion. Arrangements are made whereby the admission to the top and bottom of cylinder can be independently controlled. A reheating receiver is provided between high-pressure and low-pressure cylinders. Pistons are made of cast steel with cast-iron packing ring. Piston rods of forged steel with flange at lower end connecting to stamp bonnet. The bonnet, or connection between piston rod and stamp, is fitted with a cushioning disc of rubber. Stamp shaft guides are formed in the framing and are fitted with phosphor-bronze boxes, arranged so as to be easily and quickly removed.

The stamps make 106 strokes per minute and are provided with a signal which warns the operator when the bed of ore on the die is becoming too thin for safety. The high-pressure cylinder receives steam at 140 lb., and the low-pressure cylinder at 35 pounds.

The capacity of these stamps is tremendous to one who is familiar only with the gravity stamp which is such a common machine in Western gold mining regions. Those at the Ahmeek crush 625 tons of ore per day each, with far less noise and vibration than would accompany the operation of a 50-stamp gold-mill. The mortar boxes are fitted with two screens, steel plates punched with ⅝-in. round holes, placed in front and back. In the ordinary course of operations these plates last about three weeks. The stamp shoes weigh about 700 lb. when new, and have a useful life of about 13 days. At the end of that time they are worn to a weight of from 300 to 325 lb. and are removed.

Gold valued at $61,400,000 was imported into the United States in 1912, namely in the form of ore and bullion.

TABLE OF CONTENTS

EDITORIAL

STORMS 'held up' the transcontinental trains this week, but the California Board of Control overlooked the opportunity to accuse the State Mineralogist of train robbery.

LITIGATION in the Coeur d'Alenes is rife at present, and the end is not yet in sight. The case in the District Court brought by the Stewart Mining Company against the Ontario Mining Company has just been decided in favor of the latter. A new trial will be asked.

CONGRATULATIONS are due to Mr. J. A. Holmes and the United States Bureau of Mines, as that useful institution is hereafter to be titled. Congress has passed the bill definitely extending the work of the Bureau to Western metal mines and clearing up many other doubtful points in the original law.

CONVERTIBLE bonds to the amount of $5,000,000 are to be issued by the Granby Consolidated Mining, Smelting & Power Company, Limited. It had been planned to finance the new work at Hidden Creek out of operating profits, but pressure for dividends has resulted in declaration of a 1½ per cent disbursement with simultaneous announcement of the bond issue.

PRESENTATION of the John Fritz medal to Mr. Robert W. Hunt, in New York recently, marked a pleasing recognition of excellent work. To engineers generally the award was the more pleasing because Mr. Hunt has stood first of all for scientific accuracy in steel making. Previous awards have been to Lord Kelvin, Thomas Edison, George Westinghouse, and Robert T. Porter, excellent company for any engineer.

FURTHER details regarding the State Mining Bureau of California were made public this week. In a widely published letter Mr. W. H. Storms stated that the active opposition of the Governor had only been incurred when he discharged two political incompetents who had been given places at the request of the Governor. It was *post hoc*, if not *propter hoc*, that the Board of Control became active and made the groundless charges we discussed last week. Upon publication of this letter the Governor announced the removal of Mr. Storms and appointed Mr. Fletcher M. Hamilton to the position. His right to discharge Mr. Storms is denied and is, we understand, subject to considerable doubt. The whole situation is a disgraceful exhibition of the effect of petty politics on the conduct of what should be an important bureau for

scientific assistance to the mining industry. We reiterate that the fundamental organization is wrong, and rights, duties, and responsibilities should be more clearly defined. The proposal, however, to substitute for State Mineralogist a mine inspector indicates a complete misapprehension of the proper functions of the two officials, and the removal of an honest capable official because he insisted on efficiency in subordinates, cannot be too severely condemned.

PHILIPPINE development is to be undertaken by a strong American syndicate headed by Mr. Edward H. Fellows. The new concern is organized along the lines of the Canadian Mining & Exploration Company, but will not confine its attention to mining. A fund of $3,000,000 has been raised for preliminary work, and it is proposed to organize subsidiary companies to handle each new industry as developed. The parent concern will be known as the American-Philippine Company.

Secretarial Ethics

In a circular letter issued last week by Mr. Karl Eilers and Mr. Charles Kirchhoff, an attack is made upon the Committee of Nominations of the American Institute of Mining Engineers because of its failure to present the name of Mr. Joseph Struthers for another term as Secretary. The committee, which consisted of Messrs. P. N. Moore, D. W. Brunton, S. W. Mudd, C. P. Perin, John Birkinbine, and Arthur L. Walker, spent several months in careful consideration of the needs of the Institute and nominated unanimously Mr. Bradley Stoughton, of New York, for the position of Secretary; an excellent choice. Knowing the pains which the members of the committee took in studying the situation, and the high character of the men composing it, there can be but one conclusion—that the gentlemen named consider the best interests of the Institute to demand that a change be made in personnel as well as in policy in the conduct of the Institute. In this we heartily agree with the committee, and in all of it there is nothing personal. The objections to reëlection of Mr. Struthers rest on other grounds. He is so unfortunate as to be intimately concerned with certain policies in the conduct of the affairs of the Institute, policies that we and many others believe should be eradicated. The fact that he and his friends see nothing to condemn in these, makes it necessary if possible to eliminate them from control.

The whole matter is in one sense academic. If the new constitution and order of business be adopted by the members, and we believe they should and will be, selection of the Secretary will be taken out of the hands of the membership at large and made a function of the enlarged Board of Directors. The latter will be in fact as well as in law the governing body of the Institute, and the Secretary, being an employee of the Board, will, properly enough, be selected by it. Nominations of members of the Council and a Secretary of the Council, have only been made in order to fulfill the terms of the law; in fact, it is hoped that the Council will cease to exist February 18 when the ballots in favor of the new constitution are counted.

In view, however, of the attack made upon the nominating committee, it is but fair to state the situation squarely. Mr. Struthers, in a circular letter to the members some weeks since, presented his candidacy upon the basis of his record, and appeal having been made upon that basis, it is proper that attention should be called to certain facts in the record that are matters of public knowledge. In brief, *the position of Assistant Secretary, and later of Secretary of the Institute, has been used to make money out of members of the Institute in addition to the official salary.* The facts are all stated in the report of the Committee of Five distributed last June, though in such form as to have escaped attention of many. In connection with meetings of the Institute it has long been customary to arrange excursions from New York to the meeting place and return. Frequently these excursions have been continued beyond the place at which the formal sessions were held. Many members of the Institute have enjoyed the excursions and these have contributed materially to its popularity. We have already expressed our approval of the policy of having such excursions and the opinion that the legitimate expenses of the Secretary on such occasions should be paid by the Institute. Because of a supposed inability of the Institute to assume financial responsibility in such cases, it has been customary for the Assistant Secretary, and lately the Secretary, to conduct them as private business ventures. No statement of profits or losses, if any, has ever been made public. It has lately become known that the excursions have resulted in material profit. Perhaps this would be, as maintained by the Secretary, purely a private matter between himself and participants, if it were not for the following facts. Quoting from the report of the Committee of Five, "there was interminable correspondence conducted in large degree from the Institute headquarters, on Institute stationery, and at Institute expense. There has been at times an assistant engaged from outside the Institute membership to attend to these details of business, but at a salary paid from the Institute funds. During the excursions the salaried officers in the Institute's service, except the office force of clerks, have usually participated in the trips, and mostly at Institute's expense." The committee segregated expenses on account of excursions amounting to $8373.77, covering 1904 to 1911, and stated, "there have been further expenditures incurred for circulars, postage, and conducting of correspondence which are impossible to segregate." The cost to the Institute for participation in the excursions in 1909, connected with meetings at New Haven and Spokane, amounted to $1639.45. In this sum was charged the expenses of the Secretary, and Assistant Secretary, *and of the extra employee hired at Institute expense to attend to the business of the excursions, the profits on which went to private individuals.* In other words, the Institute itself was put to extra expense in order that a favored few might make a profit. As already stated, the amount of this profit

is unknown, but whether large or small, the principle, we hold, is wrong. In one instance when objection was made to an unexpected bill for extras sent to participants in an excursion, the Secretary admitted that if none of the members paid the bill he would still not lose money on the excursion. Since the total for extras amounted to approximately $5000, the expected profit was certainly not less than that sum; a tidy little addition to a year's salary. As illustrating the point of view of those who fail to see anything to condemn in this situation, it is worth while to repeat the defense made by one of the Secretary's friends. He urged that such profits were entirely reasonable and proper, and stated with evident approbation, that on an earlier excursion an Assistant Secretary had enjoyed in addition to other sources of profit, a commission on money spent in the dining cars of the special train. With those who accept this as a defense there is no room for argument. We merely respectfully differ, and differing, we urge all who wish a complete change in the conduct of affairs to support the Committee on Nominations, to vote for the new constitution and new order of business, and not to fail to execute promptly their proxies in favor of Messrs. James Douglas and A. R. Ledoux. As Mr. Douglas points out elsewhere in this issue, in the evolution of institutions, the time comes when one-man control must give way to a larger participation, and it is desirable that the change be made with as few heartburnings as possible. But, we would point out, the change must be made if the Institute is to retain the confidence of its members.

Electric Hoisting Problems

Development of electric hoisting during the past decade has been extraordinarily rapid, and what has been accomplished in adapting electric motors to the work of hoisting at high speeds from great depths is known to but few. The electric hoist most familiar to the average man is found on elevators in office buildings, where the slow rate of hoisting and the moderate height of lift make the use of an electric motor both easy and convenient. When electric power began to be generally available throughout many parts of the West its advantages for the operation of small hoists, both above and underground, were quickly recognized. The disadvantage of the high peak load incurred in starting the cage or skip was as quickly perceived, and modifications of motor construction were made to better adapt them to hoisting purposes. Starting torque is the prime essential in the choice of an electric motor for hoist service, and the development of the intermittent service type of motor greatly improved the service rendered, though did not appreciably better the load factor upon which contracts for power are commonly based. In the case of small hoists this is not a serious matter, especially where a number of small hoists tend to average their peaks. In the case of large electric hoists, such as that at the Hecla mine, in Idaho, recently described in these columns, this difficulty has been met by the use of a heavy fly-wheel, or Ilgner transformer, as it is generally known abroad, and the service rendered by electric hoists of this type has been highly satisfactory.

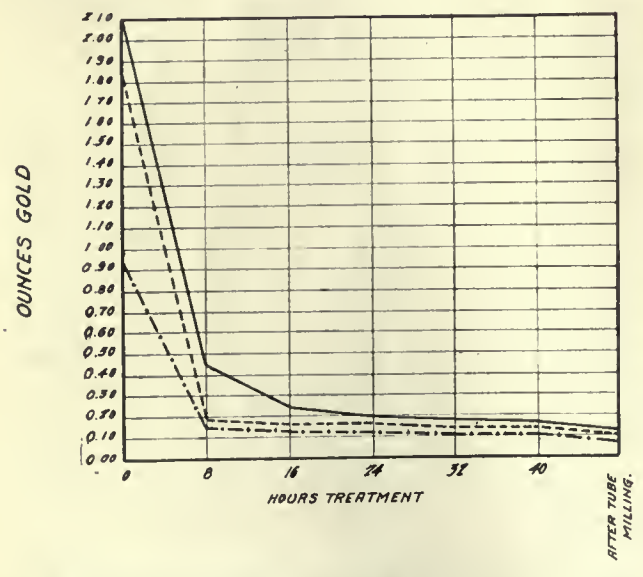
Electric hoists in this country have not, however, so far been built for hoisting from great depths at high speeds. The Hecla hoist has an ultimate working depth of 2400 feet, but is not now working beyond 1200 feet, presumably at a speed not greater than 1000 feet per minute. On the Rand, electric hoists have been used for depths of 4000 feet in vertical shafts and 5000 feet on inclines, the maximum hoisting speed being 3500 feet per minute, and have given such satisfaction that it is unlikely that additional steam hoists will be constructed, now that the Victoria Falls & Transvaal Power Company, Ltd., has made an ample supply of electric power available. In a recent paper presented before the North of England Institute of Mining and Mechanical Engineers, Mr. A. W. Brown has described South African practice in this regard, and his description of the plant at the Brakpan No. 2 shaft, where an induction motor hoist, driven through hand-operated tooth clutches, is used for hoisting ore, will be of great interest in this country. The use of tooth clutches is peculiar, from American standards. For lowering and hoisting men as well as ore, a motor-generator set, with Ward-Leonard control, is used, similar to the Hecla hoist. For control when lowering at the high speed used, mechanical brakes need to be supplemented by power braking, and an interesting electrical brake has been developed. This, to quote Mr. Brown, consists of "a water-cooled stator of cast iron surrounding a field-magnet system similar to that used in the engine-type of alternating current generators, and keyed to the drum shaft. When the magnet-ring rotates, and the field is excited, the induced eddy currents in the stator exert a powerful drag on the magnet-ring, thus giving a braking effect without mechanical friction. In actual service this brake has shown itself capable of lowering an unbalanced load of 9000 pounds at a speed of 200 feet per minute, and of controlling the rate up to the full speed of 3500 feet per minute." A similar result is attained in the hoists in use here by weakening the generator field while the motor is running, the functions of the set being thus reversed, the motor operating as a generator, and the generator as a motor delivering mechanical energy to the fly-wheel. In either case, in the event of failure of the power supply, the braking effect would at once vanish, reducing the hoist to dependence upon the mechanical brakes. The risk involved where the lowering of large numbers of men to great depths is a feature of everyday work, is evident, so the matter is giving South African engineers much concern, and the appointment of a commission is urged by the *South African Mining Journal*. To a hasty observer it would appear as though the problem might be quite simply solved by the use of an exciter, direct-connected to the drum shaft, the braking effect thus being rendered independent of the power supply. Solution of the problem by our antipodean colleagues will be of much interest to engineers in this country, since deep level mining is becoming more a factor our practice. In an early issue we expect to publish an interesting study of the factors governing the choice of a motor for hoisting service.

Treatment of Concentrate at the Goldfield Consolidated Mill

By J. W. Hutchinson

Since this article is intended to supplement the series which appeared in the *Mining and Scientific Press* during May and June of 1911, those interested are referred thereto for a description of the former process for treating concentrate.

It will be necessary to say here only that the acid wash, bromo-cyanide, and peroxide that were formerly applied to the raw concentrate have been discontinued. The concentrate, previous to roasting, is subjected to a preliminary treatment with alkaline cyanide for the purpose of reducing the value of the material to be roasted in order to minimize the dust loss. For instance, the loss in roasting has been determined to be approximately one-half of one per cent of the value of the material roasted. When the roasting plant was put in operation the raw concentrate entering the plant assayed 10 oz. in gold. The loss on concentrate of this grade would have been $1 per ton. The preliminary treatment given before roasting removed 85% of the value, leaving a product to be roasted valued at $30, and the loss in roasting this material was 15c. per ton. Further, it was demonstrated conclusively in the laboratory that neither a complete raw treatment nor treatment of the rich concentrate after roasting would yield so complete recovery as the combination of the processes, and that this combination treatment could be given as economically as either of the single treatments. For this reason it was decided to dispense with all the more expensive details of the raw process and to roast the tailing from this modified raw treatment.



The raw concentrate recovered from the 78 Deister concentrators (the 16 secondary tables are not now used), amounting to 6% of the weight and containing 67% of the value of the ore, is collected in flat-bottomed tanks, equipped with the adjustable square shaft agitator, which was fully described in the former articles; it is here neutralized with lime and by means of a centrifugal pump elevated to three Pachuca agitators, in which it is agitated during 8-hour periods in a two-pound solution of cyanide. Decantation at the end of the period is still practised and the charge is re-agitated with a freshly precipitated solution. Five periods of 8 hours each, followed by decantation, are sufficient to remove from 80 to 85% of the value of the concentrate. It is the intention to send to the roaster a product valued at $25 to $30, and this treatment is varied with the grade of the ore so as to accomplish this result. The pulp from the Pachucas, when dissolution is completed, is delivered to a storage tank from which it is pumped to the Kelly filter-press for filtration and drying. The latter is accomplished with air and the moisture is reduced to 12%. The consumption of cyanide during the raw treatment is 2½ lb. per ton of concentrate, and lead acetate is used in the proportion of 1 lb. per ton.

By means of a hoist and scraper, approximately 20 tons per day of the accumulation of concentrate on the dump is conveyed to the Kelly press bin and mixed with the concentrate filtered. A 14-in. conveyor, set at an angle of 17°, receives the concentrate from this bin, passing it over a Blake-Dennison automatic weighing machine en route to the bins in the roaster plant. The concentrate from this conveyor is distributed by means of a swinging bucket elevator to two bins having 45° sloping bottoms and 1620-cu. ft. capacity, from which it is fed by means of two 12-in. screw-conveyors, making three-quarters of a revolution per minute, to two slow-moving belts. These belts discharge the concentrate through the arches of the furnace between the first two rabbles. The original feeding arrangement was a 12-in. screw-conveyor, 23 ft. long from the ore-bin to the furnace. The strain caused by the packing of the concentrate made this machine impractical. The screw was cut down to 10 ft. in length and used for feeding only, and the concentrate is now conveyed from this feed-screw to the furnace by the belt above mentioned.

Roasting is accomplished in two Edwards (54 spindle) duplex furnaces, 112 ft. long by 13 ft. inside, with an effective hearth area of 1456 sq. ft. each, and each furnace is capable of roasting 40 tons per day of concentrate, of which the following is a typical analysis, the average sulphur content being 18.76 per cent:

Mesh.	Weight, per cent.	Sulphur, per cent.	Total S, per cent.
100	9.5	5.34	2.70
150	8.5	11.74	5.27
200	22.5	18.59	22.28
—200	59.0	22.37	70.30

The hearth area required per ton of concentrate roasted per day is 36.40 sq. ft., equivalent to 55 lb. of concentrate per square foot per day. The slope of the hearth is ¼ in. per foot. The space between the furnace side-walls was filled with waste from excavations to within one foot of the hearth-line. This material is decomposed surface rock full of clay. It was wetted down and tamped thoroughly and cov-

ered with one foot of screened sand to form the hearth, in order to reduce the breakage of revolving parts. Since all details of construction can be obtained from the accompanying figures,* there is no necessity for repetition. There are two rows of 27 rabbles; 25 of these revolve at 2.25 r.p.m. and the last two on the finish at 4.5. This speed was decided on after testing the furnaces at speeds varying from 1.6 r.p.m. to the speed now used. Lower speeds did not reduce the sulphur in the discharged product, decreased the capacity, and in no way affected the dusting. In addition to being a most satisfactory furnace to operate, the Edwards has the distinct advantage of producing a minimum of dust. The fear of serious loss from this feature of roasting caused the delay in adopting the two-stage treatment. That it was groundless has been proved by operation. Only 1½% of the material roasted passes out of the furnace as dust, and only ½% is lost. When the accompanying analyses quoted and that below are considered, the performance seems remarkable:

Mineral.	Percentage.
SiO_2	51.60
Fe	19.90
S	18.93
Al_2O_3	2.00
CaO	0.20
MgO	0.10
Sb	0.08
Te and Se	0.46
Cu	0.50

One man per shift operates the entire plant, including feeding, firing, oiling, and attending cooler and elevator. The bins are filled on the day shift, and have sufficient capacity to run for 24 hours. Each furnace receives power from a 10-hp. motor, and including the feed-screw and belt, which are driven from the furnace shaft, requires 4½ hp.

At the start all the fire-boxes were used for several weeks. The first to be discontinued were the middle boxes. For several months thereafter fuel was burned in the front boxes and on the finishing hearth. As stated above, the moisture in the material fed the furnace averages 12%. Approximately 6 sq. ft. of hearth area per day ton is required to remove this moisture, and the concentrate is not thoroughly dried until the fourth rabble is reached.

An attempt was made to discontinue the fire in the front box, with the result that the moisture traveled farther down the furnace and a decided decrease in capacity was caused. It was then decided to dispense with the fires on the finishing hearth and to burn all the oil required in the front boxes. This is the present practice and has resulted in reducing the fuel consumption approximately 45%. Nine gallons of crude oil is required per ton of concentrate, equivalent to 3.3% of the weight. The sulphur begins to oxidize at the seventh rabble and is burning freely at the tenth. Doubtless because of the extremely fine state of division of the sulphide, after once becoming ignited, roasting is carried to satisfactory completion without additional fire at the finishing end. This, of course, is contrary to the usual practice when roasting previous to cyanidation, since it is customary to raise the temperature at this point, but it has been demonstrated conclusively here to be the most economical practice for this material. Were roasting ahead of chlorination being done, the scheme would not be feasible, since a dead roast would be required and the soluble sulphur would be objectionable. However, at this plant the treatment required by the roasted material prior to cyanidation, removes the sulphate and obviates the necessity of a complete roast. It is no doubt true that the fineness of the pyrite makes this practice possible and that coarser concentrate would require different treatment in the roaster. E. D. Peters in his 'Principles of Copper Smelting' makes the following observation:

> Theoretically, the smaller each particle of sulphide, the more rapid and thorough will be its oxidation. It takes an appreciable time for the oxidation process to penetrate into the centre of even a very small particle of the sulphide mineral. It begins its work upon the surface, and the more surface it is allowed to operate upon, the more oxidation there will be in a given space of time.* * * Consequently, if there were no disadvantages arising from the employment of very finely pulverized ore, it is evident that there would be no limit to the fineness at which it would be advantageous to have our ore for roasting; so that, if it were as fine as soot or rouge powder, it would roast instantaneously, * * * but in practice there are difficulties which more than offset the advantages arising from the rapid and thorough oxidation of this very fine ore. Among the more obvious of these difficulties are: the great expense of pulverizing ore to this fineness; the enormous production of flue-dust in the roasting furnaces from the fine particles carried away by the draft; the tendency of the sulphide particles to melt from the heat arising from instantaneous oxidation; the fact that such excessively fine ore lies solid in the roasting furnace, offering no interstices for the penetration of air into the deeper layers.

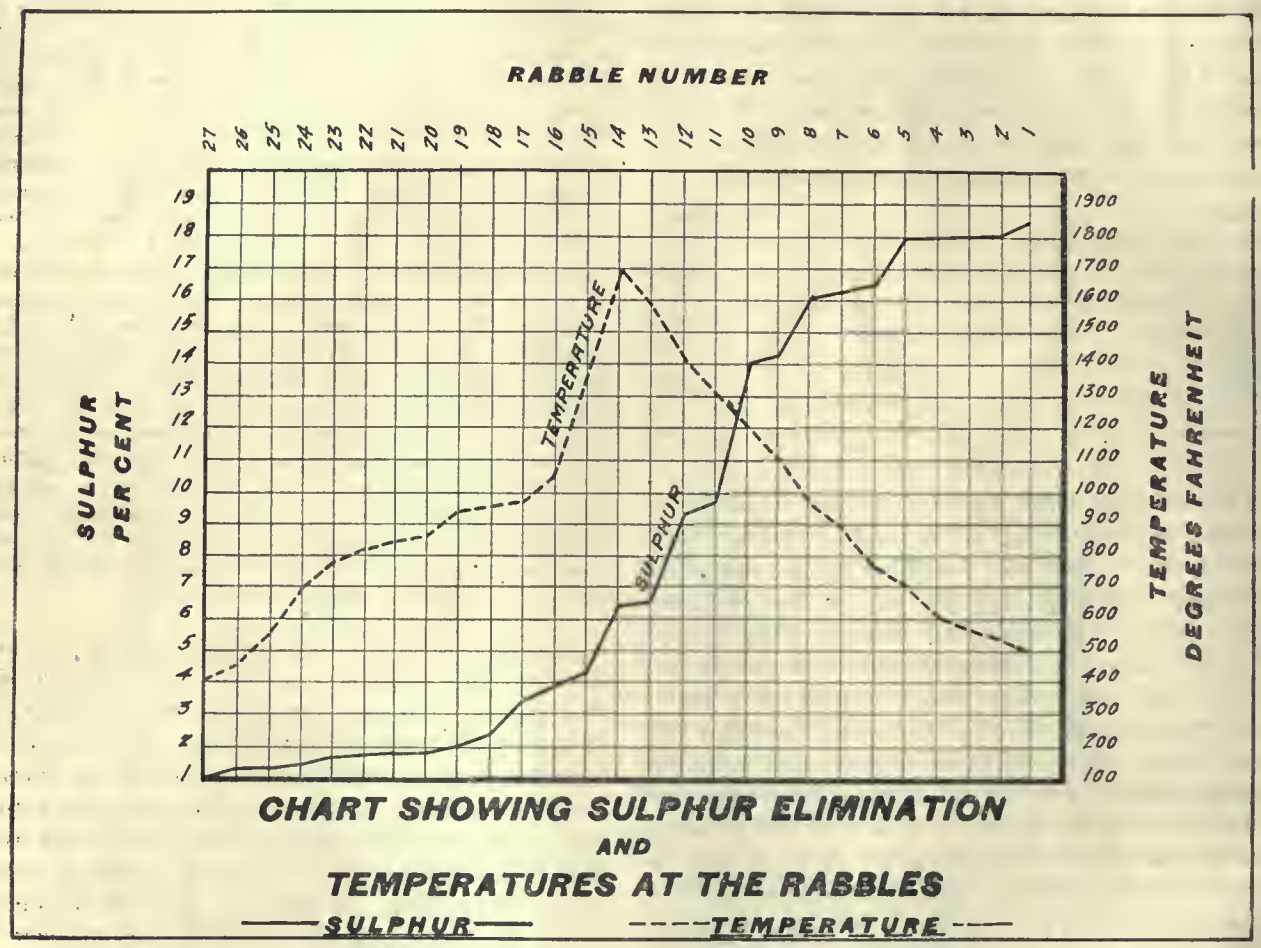
As can be seen from the screen analysis, the product fed the furnaces has been pulverized so that 80% passes a 150-mesh screen and this 80% contains 92½% of the total sulphur. Obviously, the problem here has been to avoid excessive loss from dusting and the melting of particles. In the matter of admitting air to the hearth, the practice here varies from the usual in that all side ports are kept closed, except six near the finish. In this way, most of the air entering the furnaces is preheated by passing over the practically roasted ore before it reaches that port of the furnace where heat is required, and thus saves fuel by not excessively reducing the temperature at this point. With a given degree of comminution the factors governing the oxidation of pyrite are, time, temperature, and oxygen. The first is inversely proportional to the last two. For instance: Oxidation at the surface of the earth is accomplished in long periods of time at low temperature and an abundance of oxygen; the same chemical result can be obtained in an assay muffle in 60 minutes with high temperature, while in practice the result is obtained in a number of hours. Since the combustion of sulphur produces dead atmosphere, and since combustion ceases entirely when the amount of SO_2 in the surrounding air reaches 12%, it follows that oxidation proceeds more rapidly in pure air than in air diluted with reducing gases. However, since a large excess of air or draft increases fuel consumption and stack losses, the economic limit of any furnace is reached

*See part II.

when the decrease in cost of labor and power resulting from increased capacity is more than offset by the increased cost of fuel and increased stack losses. This point has been demonstrated here by repeated tests. There is no difficulty in increasing the capacity of the furnaces by burning more fuel and increasing the draft, but there is no resultant economy from such increase on this extremely fine material. Since the element of time is not only essential, but an economical factor in the commercial oxidation of pyrite, it seems that where the tonnage to be treated is sufficient to justify the increased capital outlay, greater economy can be effected by allowing greater hearth area per day-ton of concentrate roasted. The material roasted here is so out of the ordinary and requires such unusual treatment, it has been thought advisable to go quite into detail in order to explain the theory on which the practice is based.

The accompanying chart of temperatures and sulphur elimination will show the progress of the concentrate through the furnaces. All temperatures were taken with a Brown electric pyrometer, using a platinum-rhodium couple, and for the sake of uniformity the readings were taken one foot above the hearth-line. The concentrate loses 17% of its weight in roasting.

(To be Continued)



Silver miners of the world must consider the currency of the Orient a matter of paramount importance. No little space has been devoted to discussions of the recent tendency of India to hoard gold in the same manner as it was formerly accustomed to hoard silver. A large demand for silver has been anticipated in the awakening and reorganization of China. It is, therefore, important to silver-producing properties that it is proposed to put China on a gold-standard basis. G. Vissering, of the Bank of the Netherlands, Amsterdam, Holland, has attracted much attention by his suggestions for a reorganization of Chinese finances and the establishing of a 'gold exchange' standard similar to the system which Mr. Vissering put into force in the Dutch East Indies. China's needs for currency reform are imperative, and it is quite conceivable that in order to conform to the prevailing standard of the civilized world a gold basis will be established. But in any case, it is likely that silver will indefinitely continue in use by so conservative a people, since the Chinese distrust bank-notes unless the solvency of the banks is unimpeachable. Silver producers have during the current year taken much hope from the better outlook. A price of 63½c. ruling during the past three or four months, as compared with 54c. a year ago, has been a matter of no little encouragement; encouragement which would have resulted in considerably increased output had it not been for the unsettled conditions in Mexico during the past year and a half; conditions which preclude the enlisting of any new capital for mining enterprises of any kind in Mexico, whether gold or silver. As a result, the large low-grade silver orebodies, with higher prices to make developments possible, have had to see a better silver market without any progress being made in mining. In the meantime the gold output of the world shows every sign of decreasing. Only the increase on the Rand prevented a fall in output last year.

Mining on the West Coast of South America

By Howland Bancroft

Throughout the year just passed, South America received an increasing amount of attention from the mining and investing public, and the mining industry of that part of the continent with which this article deals was characterized by steady progress. Exploration was carried on in all of the Republics in the western part of South America and many new projects were launched. With few exceptions the better known mining companies maintained or increased their output. The following account of present conditions in the Republics of the West Coast is based upon personal observations in Peru, Bolivia, and Chile, and published notes on Colombia and Ecuador.

Colombia

Precious metals represent Colombia's principal mineral output and of them gold is far in excess of silver. From the department of Antioquia it is estimated that the 1912 production of gold will be in the neighborhood of $2,500,000, which represents the major share of the total gold production of Colombia.

Gold.—The El Recreo mine, in the department of Tolima, is reported to have produced some 860 oz. of gold bullion, netting $19.20 per oz., from 1244 tons of ore taken out in development from September 1, 1911, to August 31, 1912. The Gauleala Mines Co. owns a large area of mineral land in the district of Mallama and during 1912 is reported to have erected a modern cyanide plant. Details of operations are lacking. Drilling for dredging operations on the Cauca and Nechi rivers in the department of Antioquia is said to have met with success, and the Breitung Mines Corporation has been formed to expand the mining activities of Breitung & Co. of New York. The Oroville Dredging Co. of California is about to begin work with a modern dredge on the Nechi river near Zaragoza, and two other American companies are considering the placing of dredges on the Cauca. The Colombian Mining & Exploration Co. owning gold and silver mines in the districts of Supia and Marmato, in an annual report for the year ended September 30, 1911, states that developments have been satisfactory. Ore reserves of the Marmato Hill mine, the principal property of this company, are stated (September 30, 1911), to be 81,547 tons averaging 0.48 oz. gold. During the year covered by the report 15,399 tons of ore was milled and 7400 tons cyanided, with a total recovery of $166,511. The semi-annual report of the Frontino & Bolivia Co. for the six months ended December 20, 1911, shows a loss of $21,054, being the excess of working costs over the revenues. This company reports 17,147 tons of ore raised from the Silencio, Salada, and Donagan's mines, the yield being 6296 oz. gold. Ore reserves on December 20, 1911, are stated to be as follows: Silencio 8769 tons averaging 0.9 oz.; Salada 9534 tons averaging 0.4 oz; and Donagan's 5863 tons averaging 0.225 oz. At Amalfi, an American company is reported to be running a bedrock adit 1000 ft. preparatory to commencing hydraulic operations. In Anori, another American company is reported to have commenced work on a 2000-ft. adit. On the upper Porce river, Colombians are said to have obtained over $130,000 worth of gold in two years working the Gabine mine. The La Clara mine, in the vicinity of the Gabine, is said to have yielded $30,000 to American operators in four months.

Miscellaneous.—The Tolima Mining Co. had a successful year. The report issued, covering the year ended June 30, 1912, states the silver production to have been 649,844 oz. The profits for the year amounted to $92,971, out of which a little over one-half was devoted to redemption of debentures and about one-quarter was distributed as dividends. The La Lozana and some adjoining platinum properties near Buena Ventura are reported to have been purchased by the Consolidated Goldfields of South Africa. Deposits of copper, iron, coal, and petroleum have received some attention during the past year, but developments have not been extensive.

Ecuador

Ecuador has not received the attention that the mineral deposits of that country would seem to warrant, and but little mining news of importance is to be chronicled for 1912. The principal gold producer of Ecuador is the South American Development Co., which operates a lode mine north of Guayaquil. A company is reported to be dredging placer ground in the province of Esmeraldas. Gold-bearing quartz veins are reported at Gualaceo and in the southern part of Ecuador. Promising gold placer deposits are said to occur in abundance on the eastern watershed from the province of Loja to the province of Imbabura. In the western part of Ecuador the gold placers of the province of Cuenca are reported to be the richest. Deposits of copper, iron, lead, silver, and coal are known to exist in Ecuador but have received little attention. This is possibly due to the fact that transportation facilities are meagre and until more railroads are built there are but small chances of utilizing the mineral wealth of that country.

Peru

Projected railroads and a revision of the mining laws kept pace with the increased mining activity in Peru during 1912, and many important developments have taken place. Copper, silver, petroleum, and vanadium head the list of mineral products in point of production.

Gold.—In Peru the Inambari Gold Dredging Concessions, Ltd., is considered the principal company operating gold placer property, having taken over the Inca Gold Development Co. property in the Carabaya and Sandia districts. A dredge was completed during 1912 and commenced operations. The New Chuquitambo Gold Mines, Ltd., operating a mine, 40-stamp mill, and cyanide plant at La Quinua,

PANORAMA OF CERRO DE PASCO 'TAJO,' REPRESENTING THE SURFACE WORKINGS

near Cerro de Pasco, is crushing and treating from 2000 to 3000 tons of low-grade ore monthly. Some difficulties have been experienced in treating the ore, but experiments have been conducted with a view to eliminating the trouble and an 85% extraction of the metals is looked for by the management. The Aporoma Goldfields, Ltd., commenced hydraulicking on its placer deposits in the province of Sandia, Peru, and a test clean-up on May 31, on 6000 cu. yd. of gravel yielded 46 oz. gold. The cost of treatment is said to be 4.6c. per cubic yard. The deposit is reported to cover two square miles and to vary from 50 to 400 ft. in thickness. The Nueva California placer deposits in the province of Aymares are reported to have been investigated, and in the Potaz district some development work was accomplished. Frank Klepetko and Frank Bryson are said to have a concession to develop gold-placer ground along the Santa and Chuquicana rivers. The Sociedad Aurifera Andaray-Posco, Ltd., in the province of Condesuyos is reported to have commenced producing.

Silver.—Peru ranks about even with Bolivia as a producer of silver, these two Republics contributing four-fifths of the silver production of South America. The company owning the silver mines at Caylloma has been reorganized as the Sociedad Explotadora de Caylloma Consolidada with a capital of £100,000, in 400,000 shares of 5 s. par value. A deep drainage adit over 8000 ft. long is being driven at the rate of about 100 ft. per month to tap the orebody on the eighth level. The Colquilisca mine is shipping ore to the Huarueaca smelter from which is recovered about 1,500,000 oz. silver annually. This mine and smelter belong to E. E. Fernandini. A small cyanide plant, erected to treat a large tonnage of silver tailing resulting from arrastre operations on oxidized ores of the Cerro de Pasco deposit, proved unsuccessful.

Copper.—The Cerro de Pasco M. Co. continues to be the largest copper producer in Peru and ships from 3,500,000 to 3,700,000 lb. per month, of which a portion is from custom ore. The Backus & Johnson smelter at Casapalca has increased its output to about 700,000 lb. copper matte per month and is reported planning to double its output by blowing in another furnace. From 500 to 600 tons of ore, carrying from 8 to 15% copper and from 10 to 40 oz. silver per ton, is shipped daily from the Morococha district to the Casapalca and Cerro de Pasco smelters. The greater part of the production comes from the Morococha Mining Co., controlled by New York men affiliated with the Cerro de Pasco company. The Docena mine at Cerro de Pasco shipped about 8000 tons of copper ore per month to the Cerro de Pasco smelter. The Peruvian Mining, Smelting & Refining Co. is reported to have failed, due to lack of ore. Development work was actively pushed throughout the major part of the year on the Ferrobamba property. A. C. Burrage is reported to be developing a copper deposit near Huancayo in the province of Tajacaya. An option on the Sayapullo properties is said to have been given to French interests. The Huinac Copper Mines, Ltd., in the province of Huarez was absorbed by a company formed in London in July, known as the Huinac Consolidated Copper

CERRO DE PASCO SMELTER AT LA FUNDICION, PERU.

SMELTER AT CASAPALCA, PERU.

Co., Ltd., and having a capital of $2,000,000.

Miscellaneous.—Sulphur is being produced in the department of Piura by the Sociedad Azufrefa de Sechura, and deposits of sulphur are reported to have been discovered in the southern part of the Republic. The American Vanadium Co., operating the mines at Minasragra, continue shipping patronite ores and are credited with producing a majority of the world's vanadium output. Coal ash from a deposit near Huanuco, said to contain 25% V_2O_5, attracted some attention to this new field. Asphaltite deposits of Yauli, said to contain 1% V_2O_5, are reported to contain from 25 to 40% V_2O_5 upon being burned to an ash. Emeralds have been discovered in the department of Cuzco near Chuquicahuana. The dump ores and selected argentiferous zinc ore of the Carahuacra mine, now controlled by the Sociedad Minera de Carahuacra, Ltd., are being treated by pan-amalgamation with a 60% recovery of the silver content. The management is reported to be considering the installation of the process of the Minerals Separation Co., Ltd., to effect a saving of both zinc and silver. Two tungsten properties in the Conchucas district are reported to have received some development and small mills are said to have been erected on both properties. Bismuth ore was concentrated in the plant of E. E. Fernandini. In the province of Aymares nitrate fields are said to have been discovered in from Chala. The oilfields of northern Peru have continued to increase their output, a large part of the product having a local market. The fields are of especial importance because of the high grade of the oil. Coal lands have been denounced in connection with the Burrage copper project beyond Huancayo and will be developed.

Bolivia

The mining industry of Bolivia has been materially benefitted during the past year by the completion of the Arica-La Paz railroad and the extension of several branch lines connecting with the Antofagasta á Bolivia and the Bolivian railroad. Tin continues to be the chief mineral product of this country and considerable interest has been shown in explorations for deposits of this mineral. The silver production remains about normal. Copper deposits in Bolivia have not received the attention that they warrant and no new developments of note have been reported. Petroleum fields in the southeastern part of the Republic have been investigated and the coal deposits of the Titicaca region cause occasional comment.

Gold.—Gold mining is not one of Bolivia's most important industries, in fact it hardly deserves mention as there was but little active operation during 1912 and no placers of importance were worked. The so-called 'Ferguson' letter, so widely read, caused a small stampede to the Tipuani river, but thus far no important discoveries have been reported from this region, although it has been known for a long time that placer deposits of more or less value occurred along this stream. Undoubtedly future explorations and development will bring the gold mining industry of Bolivia into a more prominent place than it now occupies.

Silver.—Bolivia ranks first as a silver producing

PANORAMA OF THE ITOS TIN PROPERTY, ORURO DISTRICT, BOLIVIA.

PANORAMA OF THE PODEROSA MINING COMPANY PROPERTY AT COLLAHUASI, CHILE. SHOWS THE SAN CARLOS AND PODEROSA HEAD-FRAMES AS WELL AS DUMPS, HAND-JIGS, AND OTHER HAND CONCENTRATING DEVICES.

country in South America, and, while there were no important new developments in the silver mining industry in Bolivia during 1912 and statistics of the production during this period are not at hand, it is to be supposed that the total output will compare favorably with that maintained for the past few years. The total output of silver from Bolivia is variously estimated at from $3,000,000,000 to $6,000,000,000. At present the annual production is in the neighborhood of 7,000,000 oz. The principal silver mines are those in the departments of Oruro and Potosi. The Huanchaca is the most famous producer of silver in Bolivia. It is to be remarked that many of the tin deposits carry appreciable amounts of silver.

Copper.—Copper mining in Bolivia is also one of the lesser industries of that Republic and the total production is estimated at from 200,000,000 to 300,000,000 lb., with an annual production ranging from 4,000,000 to 5,000,000 lb. The Corocoro native copper field is, perhaps, the best known. Here are the properties of the Corocoro United Copper Mines, Ltd., the Compania Corocoro de Bolivia, and several others of lesser importance, the two named representing the only active producers in the district. The former represents a recent consolidation of several properties now held by French interests and the latter represents a Chilean company formed in 1873. Copper is mined, milled, and put on the European market at a cost ranging from 13c. to 10c. per pound. With modern improvements now under way at the Corocoro United it is thought that costs will be reduced to 9c. per pound. The content of the ore which is hoisted ranges from 3 to 5% copper. It is concentrated up to 88%, although the average content of the concentrate is thought to be more nearly 75%, and the tailing is rewashed by Indian women with a 60% copper concentrate resulting. Other promising copper fields in Bolivia are the Chacarilla, Carangas, and Turco. A smelter has been erected at Quechisla for the purpose of producing copper matte.

Tin.—Bolivia ranks first in the world as a tin lode mining country, producing one-quarter of the world's supply of this metal from lode mines. The properties are controlled by native and foreign capital, although the United States is hardly represented in Bolivian tin projects notwithstanding the fact that this country consumes one-half of the total world's production of tin. It is interesting to note that the properties controlled by Simon Patino, a native Bolivian, yield over one-third of the total tin production of Bolivia. The La Salvadora mine in the Uncia district is probably the premier tin mine of the world and it has a yearly production estimated to be over 13,000,000 lb. of tin. The Avicaya property is another large producer with a yearly output of about 3,000,000 lb. of tin. Another large producer is the Huaina-Potosi property with a yearly production of nearly 1,000,000 lb. of tin. Among the more prominent deposits may be mentioned those of Huaina-Potosi and Quimsa Cruz in the department of La Paz; those of Morococala, Huanuni, Oruro, and Avicaya in the department of Oruro; those of Llallagua, Uncia, Potosi, and Chorolque in the department of Potosi; and those of the province of Arque in the department of Cochabamba. Of the 21 most active producers in Bolivia the majority of the tin comes from about 10 mines. There are in Bolivia over 100 tin prospects which are worked intermittently, the owners desiring to interest foreign capital in their development.

During 1912 the Porco Tin Mines Co. was formed for the purpose of developing the Porco mines in Bolivia. The ore reserves are estimated at 45,000 tons of 4.4% tin. Simon Patino is reported to have purchased the important group of tin mines at Huanuni for a consideration of $2,000,000 and by so doing he has put an end to conflicting interests in that district. Acquiring tin properties in Bolivia is not an easy matter, as mines sell on past records rather than on actually developed ore reserves and all of the owners of tin property have inflated ideas as to the real value of their deposits. Nevertheless the field offers large opportunities for future investigation. There are several modern concentrating plants in operation in Bolivia and all of the tin ore is shipped from this country as barilla, containing at least 60% metallic tin. British ports receive four-fifths of the Bolivian product, the other fifth going to Havre and Hamburg.

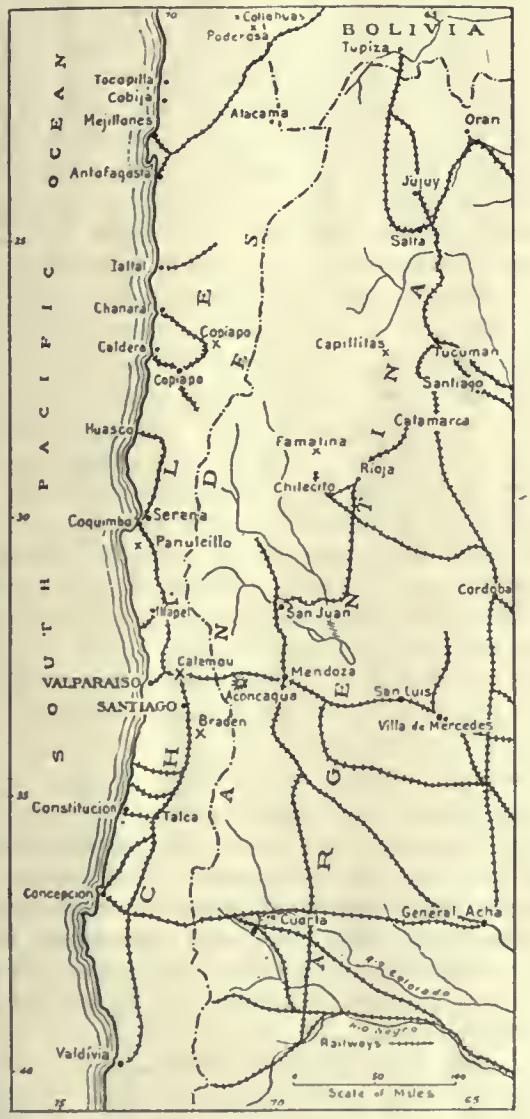
Miscellaneous.—Deposits of antimony, bismuth, tungsten, and molybdenum, which exist in Bolivia, have received but little attention during the year just passed.

Chile

During 1912 railroad building progressed notably in Chile, chiefly in connection with the Arica-La Paz railroad and the new Longitudinal Railway of Chile. Naturally the mining activity was somewhat stimulated. The nitrate industry is reported to have enjoyed a very prosperous year, while the copper production of Chile received a marked impetus due to

the entrance of Braden in the list of shippers. Exploration work was carried on for new nitrate fields, and for new deposits of coal, oil, iron, copper, and other mineral substances, and many new developments were undertaken by mining interests.

Copper.—Chile leads all South American countries in the amount of copper it produces. Early in 1912 the Braden Copper Co. entered the field of active shippers and it is estimated that over 300,000 tons of 2.5% ore has been concentrated with a saving of from 50 to 75% since operations were started. This property is reported to have 30,000,000 tons of



CHILE AND WESTERN ARGENTINE.

2.5% copper ore blocked out, with the future possibilities of a considerably larger ore reserve being developed. The ore is concentrated and smelted at the company's plant. The nominal capacity of the mill is 2000 tons per day and the smelter is equipped to handle the concentrate resulting from milling operations. Experiments on the ore by the Minerals Separation Company, Ltd., have been carried on during the year and it has been determined to adopt that company's process. Operations at the Poderosa Mining Co., in the Collahuasi district, were disappointing and the annual report for 1911 shows the loss resulting from operations during that period to have been about $82,600, which brings the total debit balance at January 1, 1912, to over $228,000 and makes the outlook for this high-grade copper property exceedingly discouraging. The ore reserves on the same date were stated to be but 21.000 tons averaging 22% copper, with 110,000 tons of 4½% ore on the dumps. The Cia Minera de Collahuasi, operating in the same district on similar deposits, continues to be a profitable enterprise and is said to ship about 3000 tons of 25% copper ore per month. The mining methods and equipment are crude but the company manages to make a considerable profit from operations. The ore reserves are reported as 100,000 tons of high-grade ore containing from 21 to 25% copper and 250,000 tons averaging 9% copper. Silver and gold contribute appreciably to the value of the ore. Operations of the Central Chile Copper Co. during 1911 proved unprofitable as shown by the annual report issued by the company to cover that period, and the adverse balance at the end of 1911 totaled nearly $50,000, of which some $10,500 represents the loss for 1911. The increased price of copper during the year just passed may have the effect of eliminating this debt. A. C. Burrage and the firm of M. Guggenheim's Sons are developing a copper property at Chuquicamata about 100 miles east from Antofagasta and about six miles from the Antofagasta á Bolivia railroad, to which a branch line has been built.

Nitrate.—The nitrate industry continues to be the chief source of revenue to Chile and the production during the first six months of 1912 was estimated at 1,218,000 tons. During 1912 the statement was published by the delegate of the Chilean government to the International Congress of Applied Chemistry that the "surveyed and certified tonnage opened up at the present time ready for extraction is fully 250.000,000 tons." Also that vast unsurveyed areas of nitrate ground were known to exist on the Chilean pampas so that "there are probably in round numbers, 1,000,000,000 tons of nitrate in the deposits of Chile." December 2, 1912, the government of Chile was reported to have held an auction sale to dispose of nitrate lands. Although a number of new plants have been put in operation it is said that the total output will not be appreciably increased, due to the gradual exhaustion of the highest grade deposits.

Iron.—The government of Chile is reported to have appropriated 100.000 pesos (about $22,000) to be used in continuing explorations of the iron resources of the Republic. In Coquimbo five groups of mines are reported to contain 200,000,000 tons of iron ore and other large deposits are said to occur in Atacama and in the departments of Vallenar, Freirina, and Antofagasta.

Miscellaneous.—The gold discovery at Putu caused some comment during the year but only small operations are reported. Tin is said to have been found in the province of Atacama. Petroleum is known to occur in southern Chile, but has received little attention. Borax deposits in central Chile are being actively worked. A new coalfield is reported to have been discoverd north of Santiago, and the sulphur deposits near Ollague have attracted some attention.

Secondary Sulphide Enrichment of Ores—III

By C. F. Tolman, Jr.

Side of the Basin Problem

*I was one of a party of engineers which examined a property, the value of which depended upon whether or not the concentration of sulphides was greater underneath the main drainage line or basin than under the side of the basin. The locality cannot be given because the problem is not yet settled, but the data are cited because they show the practical bearing of some of the points previously discussed and also that the problem is often a complicated one, and where incomplete data only are available, the conclusions are apt to be unsatisfactory. The croppings, well exposed over most of the area, consist of a stained, leached, and partly silicified schist, showing throughout a thorough speeking of the rock. These specks vary in size from a pin point to 0.1 inch in diameter, being cavities filled with hydrated iron oxide and hematite. All members of the party agreed that these speeks were the remains of oxidized sulphides, probably largely pyrite. The chief topographic features were a precipitous but low mountain range of schists, and a broad basin excavated in the softer schists at the foot of the mountains. The upper end of the basin showed attractive stains of copper carbonates and silicates, especially along fractures, but less specking than was noted below.

After the examination, development was continued in the higher portion of the basin, with a result of showing a disseminated deposit of pyrite, but lower in copper content than desired. The question now arises: Is the copper concentrated in larger amounts under the basin? Some of the questions involved are: Is the topography young or mature? Has the enrichment had time to concentrate under the central drainage line? What was the copper content of the leached area? If it contained no copper originally, no enrichment is to be expected. Does the lack of copper stains in the central portion indicate a lower grade of original ore than on the side, or does it indicate a more complete leaching? Finally, will the concentrated underground flow down the axis of the valley so dilute the copper salts that they will not precipitate the copper?

There is some difference of opinion among those interested in regard to these points, and the answer will be determined only after further development. It is to be noted, however, that a geological examination alone, without the advantage of underground workings, determined the existence of a disseminated deposit, as well as its areal extent, but could not make predictions as to the copper content.

The Length of Time Necessary for the Formation of a Commercial Secondary Sulphide Deposit

I once examined in detail a disseminated deposit, which is so instructive as an example of the first stages of the processes of enrichment, and further suggests something as to the time involved in the fashioning of a commercial deposit, that a few of the features will be sketched here, although permission to name the locality has not been obtained.

These features are as follows: A primary copper-bearing pyritization, accompanied by intense silicification, took place in the outer zone of a fine-grained porphyry which is the marginal facies of a normal coarse-grained granite intrusion. The area has been elevated recently and thoroughly broken up by post-mineral faulting and fracturing. The latter is so recent that sunken crushed zones form natural depressions that, on account of their irregularity, have been popularly explained as prehistoric mining excavations. Secondary enrichment has been initiated, appearing especially in shear zones, about 80% of the metal being concentrated in veinlets and sheeting, and the rest as disseminated particles. Enrichment underlies the hills, and the commercial ore lies directly under the silicified caps, having not reached down into the coarser granite. Oxidation has not been sufficiently active in this arid climate to produce strongly acid solutions, the latter carry large amounts of secondary silica, the chalcocite once formed redissolves more readily than the pyrite when reattacked by oxidizing solutions, and the drill-holes invariably show pyrite above the chalcocite. The enriched ore occurs far above the water-level, and apparently shows no relation to any former water-level. One drill-hole that was put down to reach water found no enrichment whatever at the water-level. The secondary sulphide deposit shows great irregularities, both in regard to thickness and capping. Most of these are explained by differences in sheeting and fracturing. A peculiar condition difficult of explanation is the occurrence of two rather distinct zones of enriched ore, between which, and above and below which, is low-grade pyrite. (See Fig. 11.)

The surface staining, the veination, etc. (the 'indications' of the prospector), are better developed here than in the case of any other of the disseminated deposit which I have examined, and casual examination suggests that one of the greatest of this class of deposits occurs here. However, further study shows that the process of enrichment is in its infancy, and it will take a geological period or two to thoroughly rework and enrich the deposit.

This example emphasizes the fact that enrichment, like most geological processes, is extremely slow. In weighing the possibilities of an undeveloped or partly developed deposit of this kind, the length of time erosion has taken place is one of the most important factors. Certain engineers would lead us to believe that they can leach rock in place in mine workings within a reasonable length of time, and if this is true they must accelerate nature's processes a millionfold. A second point worthy of note is that in the severely arid regions precipitation of

*Continued from p. 141.

sulphides may take place above the water-level, perhaps at some point where there is a local concentration of moisture. In more humid regions the water-level controls the deposition, and this is certainly true where the process is long continued. Finally, secondary chalcocite may occur below considerable amounts of pyrite (as much as 200 ft. at places in the property discussed), provided that the pyrite is above the water-level.

Climate and Enrichment

Climate is an important factor in effecting sulphide enrichment, but since the subject has not received the intensive study it deserves, data are not at hand for even a satisfactory elementary discussion. Winchell's recent article[38] gives valuable data regarding the effect of cold sub-Arctic climates. My own experience has been confined to the Western arid and sub-arid regions, and therefore the following brief discussion is inductive rather than deductive. Of the many varieties of climate[39] recognized, only three or four types will be considered.

Temperate Humid Climate of Eastern United States.—The temperate humid climate of the Eastern United States causes a rapid and complete disintegration of the material above the water-level. The abundant underground water lies rather close to the surface, so that no large amount of vein stuff has been worked over. The secondary sulphides are precipitated promptly at the very top of the underground water-level. The deposit is high grade—often nearly pure chalcocite—but the zone is thin, from a few inches to perhaps a score of feet.

Cool Climate Bordering on Aridity.—Such a climate has produced the great copper-ore deposits at Butte. The climate is not cold enough to retard the chemical action, the water-level is at considerable depths, and the amount of descending water is sufficient to attack the material above the water-level. It is not necessary to caution those who have followed the discussion thus far, that climate is only one, and perhaps not the most important, factor of the many that have combined to carry enrichment to an extreme at Butte.

Semi-Arid to Arid Climate of the Southwest.—Considerable variation of climate causes the irregularities of the enrichments which are found in the Southwest. Where there is sufficient moisture, high temperature accelerates decomposition, but in many places the deficiency of the meteoric waters leads to incomplete leaching. Unaltered sulphides may extend to the surface in one place, while close at hand stronger fissures may collect the water and cause oxidation to great depths.

Cold Sub-Arctic Climate.—This climate is least favorable to the process. Often recent glaciation has removed the secondary products that might have been developed during a preceding more favorable climate. Abundance of water, the fact that the water is close to the surface, and the frozen condition of the surface for a large portion of the year protect all but a shallow surface zone from oxidation, and the cold waters have little oxidizing power. It seems very improbable that under such conditions any commercial secondary sulphide enrichment can be formed. Winchell[40] describes a peculiar veneering of the surface rock by secondary chalcopyrite, formed under a forest-covered and constantly saturated soil of British Columbia and adjacent regions, and as I have learned from various prospectors and engineers that such a superficial coating is a common thing in this region, this may be taken as a type of enrichment under sub-Arctic conditions. If the great chalcocite deposits of the Bonanza mine, Alaska, are secondary, as suggested by F. H. Moffit,[41] they must have been formed when climatic conditions were very different from what they are at present.

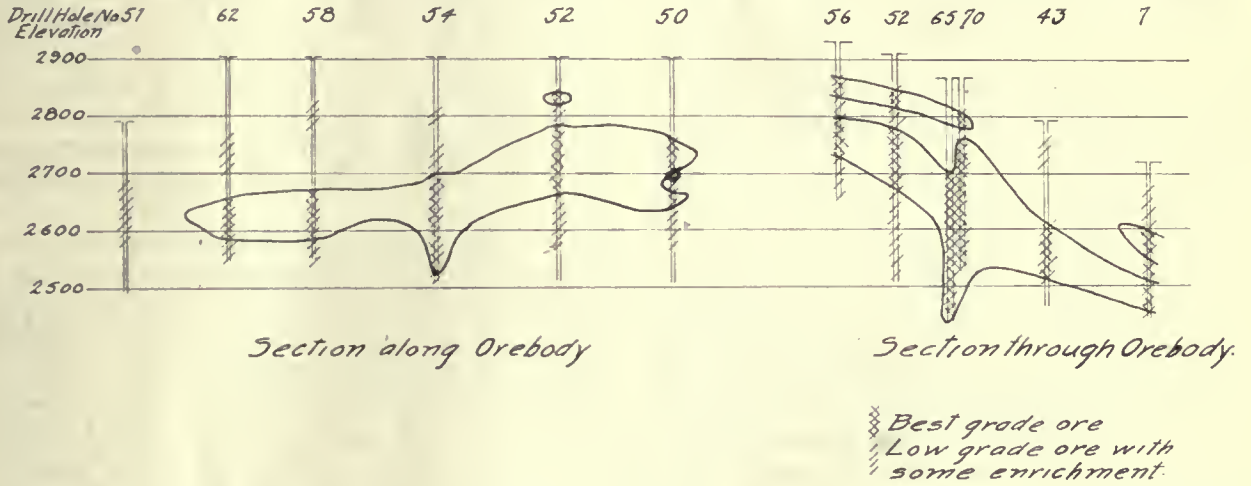


FIG. 11.

Laboratory Data

The point of immediate interest to the student of secondary enrichment is the investigation of structures and minerals in the exposed surface rock which can be proved to be residual after the sulphide veins, veinlets, and disseminations. A comprehensive discussion would include all ore minerals and rock alterations caused by all the various types of primary mineralizations, and then the changes developed in the belt of weathering. Here, however, discussion will be confined to a few of

[38] Winchell, H. V., 'Secondary Sulphide Enrichment,' *Eng. & Min. Jour.*, Feb. 17, 1912, pp. 364-367.
[39] Tolman, C. F., *Jour. Geol.*, Vol. 17, pp. 151-155, 1909.
[40] *Loc. cit.*

the more important residual structures and minerals that can be recognized by the aid of the hand lens, and which are formed above the disseminated ores of the Southwest. The original mineralization of these deposits occurs as a disseminated pyritization of the body of the rock, accompanied by sericite and quartz in a fine-grained mosaic, and by veinlets of solid, more or less cupriferous pyrite.

Enrichment first attacks the disseminated pyrite by depositing a film of chalcocite around the former, and by continued action finally replaces the entire grain of pyrite. This replacement generally destroys the sharp crystal form of the pyrite, the chalcocite appearing as 'sooty grains', although occasionally I have noted beautiful pseudomorphic replacement of large pyrite crystals by chalcocite. In many cases secondary silica completely replaces the rock, the chalcocite grains varying in size from dust-like specks discernible with difficulty under the hand lens, to specks as large as a pin-head. The massive pyrite veinlets which are barren of quartz are replaced simultaneously by quartz and chalcocite.

Under attack of strong acid solutions, kaolinization is more prominent than silicification, the chalcocite specks are always in the sooty form, the crystallographic outline of the pyrite is lost, and the pyrite veinlets are changed into massive chalcocite without the addition of silica.

Two cases must be considered: (1) The surface waters are working over a deposit of enriched ore; (2) the primary ore is attacked for the first time, and the grade of the secondary deposits depends directly upon the amount of copper in the primary deposit. It is evident that all gradations occur between ores that have undergone long-continued enrichment, and the elimination of nearly all the iron of the pyrite, to those that have received only a slight enrichment before passing into the zone of oxidation. Above the water-level the important processes are the kaolinization and silicification of the country rock, the oxidation and solution of the sulphides and the occasional development of copper carbonates and silicates accompanied by residual and vein silica.

Residual surface siliceous crusts are very common, and, on account of their resistence to erosion, cap the hills. This surface cap may be composed of a mixture of chalcedony, chyrsocolla, and copper carbonate. The residual specking and veination is often destroyed, and it may be necessary to dig below the silicious crust, sometimes only a few inches thick, in order to study the former. Similar silicious copper-stained crusts are found in the arid region where the copper stain may come from overlying formations, or from occasional veinlets, and unless accompanied by specks and indications of extensive veination, do not indicate valuable underlying deposits.

The residual specks after chalcocite appear as dust-like disseminations of hematite or limonite, while pyrite often develops small crystal casts, either empty or filled with limonite. At Ray one finds especially good examples of surface rock retaining all the structure of the disseminated enriched ore. The latter is a silicified rock, showing the schist structure and a grayish blue color from the very fine disseminated chalcocite. The surface rock appears the same under the lens, the color being red instead of blue as hematite dust takes the place of the chalcocite dust.

In general a large amount of iron in the cap rock indicates pyrite rather than chalcocite. Chalcocite veinlets below the water-level are represented at the surface by quartz veinlets, either chalcedonic or of crystalline crustified quartz. I have found numerous examples of chalcocite and pyrite veinlets grading into barren quartz veinlets above, and believe that these may generally safely be interpreted as indicating sulphide veinlets when accompanied with specking described above. Pyrite veinlets, however, show hematite, limonite, or silicious limonite veins at the surface, while chalcocite veins generally alter into pure white quartz veins.

The most intense phase of alteration is a bleaching and kaolinization of the surface rock, a good example of this being over the great Sharkey orebodies at Ray. Even under these conditions, the residual specks are rarely destroyed, although the veination is obscured. Such an alteration, in an area showing all the phenomena described above, indicates a concentration of the enrichment at this point.

Secondary sulphide enrichment is only the last one of a series of complicated processes by which concentrations of ore are formed. The earlier processes are of equal interest and often of greater importance than the one discussed here. The valuation of a secondarily enriched orebody generally involves the investigation of the series of primary ore depositions, for we cannot have an important enrichment without a strong primary mineralization. A story told by a prospector will illustrate how brilliant stains do not necessarily indicate valuable ore deposits.

He explained that he was prospecting in the Apache country of southeastern Arizona, and noted some bright copper streaks in a rock cut made in regrading the old county road. The bright copper stains seemed out of place in a rock that showed no other signs of mineralization; and climbing the cut he found the old road above, and alongside it was the wreck of a wagon destroyed and partly burned by the Indians on one of their raids. The stains led up to a point on the edge of the cut, and at this point he found some oxidized copper rivets which had fallen out of the wrecked wagon.

Pig iron amounting to 12,950 tons was shipped from Hankow, China, to the United States in 1910, but only 2425 tons was shipped in 1911. In the Chinese year from January 30, 1911, to February 7, 1912, 4465 tons of pig iron was shipped to the United States. Shipments to Japan were 58,535 tons, to Australia 5765 tons. These shipments were made by the Han-Yeh-P'ing Iron & Coal Co., which mined 359,467 tons of ore during the year and produced 93,337 tons of pig iron.

The MacNamara Mill, Tonopah

By M. W. von Bernewitz

This modern little plant has been in operation for a year and is satisfactorily treating a hard ore carrying 20 oz. silver and a few grains of gold per ton. An electric hoist, with flat ropes, at the main shaft hauls self-dumping skips of 2000-lb. capacity to the surface, where the ore is emptied into a storage-bin. The ore is fed upon a 36-in. rubber sorting-belt; about 6% is discarded as waste, the remainder then passing through a No. 3 Kennedy gyratory crusher, and is taken to the mill-bin by bucket-elevator. This bin has a flat bottom, is of 200 tons' capacity, and has the ordinary rack-and-pinion gate on the ore-chutes to the feeders.

RACK-GEARED MOTOR DRIVING STAMPS.

The mill includes ten 1400-lb. stamps, dropping 8 in., 98 times per minute, and crushing 7 tons per stamp per day, through a No. 12 ton-cap slotted screen. As will be seen from the accompanying illustration, each 5-stamp battery is driven by a 20-hp. Westinghouse back-geared motor. This may be described as a type 'M.S.', 440-volt, 60-cycle, 3-phase motor, running at 555 r.p.m., the pinion on the armature shaft engaging with spur wheel on the short pulley-shaft, which runs in bearings on the back of the motor, there being a 14-in. belt driving the bull-wheel on the 6½-in. cam-shaft. These motors have given complete satisfaction, and they were recently opened after about eight months' work, inspection showing that the tool marks were hardly worn off the gear-wheels, which work in grease. No doubt this style of drive reduces friction greatly, as there is no counter-shaft, except the little pulley-shaft, and no tightening gear for the belt. The friction in this case amounts to about 90%. Careful tests have shown that five stamps absorb 17.75 hp., including 1.61 hp. for friction, or 3.55 hp. per stamp. As a check on this reading, the following old rule can be used:

$$\frac{1400 \times 98 \times 8}{33{,}000 \times 12} = 2.77 + 20\% \text{ for friction} = 3.32 \text{ hp.}$$

It may be added that at the new Belmont 60-stamp mill there is a 60-hp. motor for 20 stamps, which weigh 1250 lb. each. This drives a short jack-shaft, which in turn drives two batteries of 10 stamps. This is similar to the drive at the Goldfield Consolidated, only there the motors are 50 hp. each, and at the Desert mill of the Tonopah Mining Co. the same is true. The West End mill has four units of five stamps each, actuated from a common motor-driven counter-shaft by friction clutch-pulleys, which arrangement gives no trouble. Besides the two motors driving the MacNamara stamps, there is a back-geared motor driving a Dorr classifier and agitator in the thickening-tank. This method of transmitting power is well worth the attention of all engineers.

Foundations for the two batteries are of reinforced concrete. The mortars (Chalmers & Williams, No. 16-E) have a heavy base, and stand on sheets of rubber; while the battery-posts are set in cast-iron sole-plates, also standing on rubber. The cam-shafts are 6½ in. diam. The ordinary Blanton cam is used, and none have been broken so far. Stems are 4 in. diam., working in Pacific guides made by the Demarest company, and none have been broken. The Pacific guide consists of a metal frame into which are fitted cylindrical metal shells that are not held by keys or the like. The screens are fitted 3½ in. from the stamp-shoes, and through a No. 12 ton-cap square-slot screen the average duty per stamp was 7 tons of ore per day, but recently coarser screens have been used, and the duty has risen to over 8 tons. Crushing is done in weak cyanide solution having a temperature of about 70°F. Feeders of the improved Challenge type, which may be called a double monkey-wrench grab, deliver the ore to the stamps.

MACNAMARA MILL.

The pulp from the stamps goes direct to a Dorr classifier, working at 12 strokes per minute, the coarse material being fed into a 5 by 16-ft. tube-mill revolving at 26 r.p.m., through a spiral feeder. Pebbles are fed in at this point, amounting to 250

lb. per day, consumption being about 3½ lb. per ton milled. Slacked lime equal to 2½ lb. per ton is added in the classifier. The tube-mill discharge is returned to the classifier by a 5-ft. Frenier pump, which gives no trouble, the coarse material again passes through the tube-mill and so on, forming the usual closed circuit, in which only the overflow from the classifier can get away. In the batteries, 25% of the ore is slimed, while the final pulp, which is pumped to a Dorr thickener, shows 73% through 200-mesh screen. This is fairly coarse when compared with other mills, but is found to be fine enough for good results.

All the classifier overflow is pumped to a Dorr thickener, 12 by 26 ft., the gear of which travels at one revolution in eight minutes. Clear solution overflows to the battery storage-tanks, and when its silver content becomes high, it is decanted off to the 'silver' tank. The thickened slime, specific gravity 1.22, flows by gravity to three 15½ by 25½-ft. Trent agitators for 48 hours' agitation in a 2-lb. KCN solution. The agitators hold 80 tons of dry slime each, and cyanide and lead acetate are added here, as well as live steam, bringing the tempera-

STAMPS, CLASSIFIER, AND TUBE-MILL.

ture up to 115 to 120°F. This has been found beneficial, as with cold solutions extraction falls off considerably. This type of agitator gives satisfaction, and even after an enforced shut-down, little trouble is experienced in starting. Air for the agitators is produced by a motor-driven compressor with 6 by 10-in. cylinders, the working pressure being 25 lb. per square inch. Each agitator has a 4-in. Campbell & Kelly centrifugal pump, direct-driven by a 7½-hp. motor, for circulating the slime through the agitator arms. From the Trent vats, the slime is pumped to a 19½ by 27½-ft. stock or storage-tank, which has a chain-driven pump for circulation.

From the stock tank, pulp flows by gravity to the vacuum plant, which consists of 50 leaves, each 5 by 10 ft., and treating 20 tons per charge. Forming cakes takes one hour, and washing two hours, with a 5-minute final water-wash at times, while the whole cycle consumes about four hours. The cloths last well, and have been on about 12 months so far. They are given a 24-hr. bath in 2% hydrochloric acid, about two leaves being treated per day. The washed slime-cakes are blown off with high-pressure water into a full tank of water, and the pulp pumped away by a 4-in. pump to ponds. Although the slime from the storage-tank goes to the filter-vat by gravity, it is helped by a belt-driven Campbell & Kelly pump, which also pumps excess back to that tank, and does the circulating in the filter-tank. In October last the filter-tank was struck by lightning and completely destroyed, save the leaves; but in a short time a new one was built.

Solutions from the filters are clarified and run through four precipitating-boxes charged with zinc shavings. The precipitate is dried to about 10% moisture in a steam-drying pan, mixed with fluxes, and melted in an oil-burning tilting-furnace. An extraction of 93% is made. The operating cost per ton in November 1912 was as follows:

Crushing and conveying	$0.176	Assaying	$0.071
Stamp batteries	0.340	Superintendence and foreman	0.233
Dorr classifier	0.145	Heating solutions	0.253
Tube-mill	0.523	Water service	0.178
Dorr thickener	0.030	Compressed air	0.017
Agitation slime	0.776	General expense	0.073
Filtering and discharging slime	0.237	Surface and plant	0.050
Precipitation	0.116	Total cost	$3.299
Refining	0.097		

New York Metal Market

The report of the Copper Producers' Association for December, issued January 8, not only showing an increase in stocks of over 19,000,000 lb., but permitting the statistics of the year to be viewed as a whole, on the heels of which came news from abroad that the Balkan situation was not mending, marked a turning point in the copper market. Immediately following the report prices softened, then declined. Future delivery metal was especially hard hit. March and April 'delivered' was in a few days offered at close to 16c., and on January 13 sales were made around 16⅛c. for these months. Both domestic and foreign business was eagerly sought, even some of the large producers directly offering concessions, or doing so indirectly by asking for tenders. Some of the trade declared that an absolutely open market existed. On January 13 an offer of electrolytic at 17⅛c. immediate delivery, was met with the statement that a large producer would sell for 17c. On January 16 the market continued unsettled and irregular, although slightly firmer because of a more pronounced disposition on the part of consumers to buy. Some buying was reported on a basis of between 16.25 and 16.40c. for delivery in Europe, with domestic sales at 16⅜c. for February and March. The situation abroad was weak from similar causes, and between January 10 and January 15, standard or speculative copper (which is distinct from copper metal, but which has a reflective effect on the commodity) dropped £6. Despite the break, consumers who have stayed out of the market except when they could not avoid buying, have continued to hold off, apparently in the hope of still lower prices. Many of them are emphatic in their assertion that 15c. is enough to pay for copper. While a good domestic buying movement will stiffen the market, it will not resume the hardness characteristic of so many months until European buying in good volume is resumed.

Determination of Copper in Matte

By Vance P. Edwards

*The method given below is one in daily use in a lead-smelting plant, and while it is based upon the standard iodometric method for copper, certain short cuts are introduced which make it possible, with practice, to turn out a copper analysis (accurate to 0.1%) in half an hour.

Weigh ½ gm. of finely pulverized dried sample into a 250-c.c. casserole with lip; cover with watch-glass; add 5 c.c. concentrated hydrochloric acid; digest on hot plate for one minute; add 5 c.c. concentrated nitric acid; heat until in solution; pipette in 5 c.c. concentrated sulphuric acid, using a pipette (the tip of which has been enlarged in order to deliver the acid as quickly as possible), placing the tip well into the casserole, the cover glass, of course, being left on. Take down to sulphuric acid fumes over a naked flame, there being little danger of bumping. When all nitric acid is replaced, remove from the flame; pull the cover glass part way off, and, if necessary, the casserole may be carefully set in a shallow pan of cold water. As soon as the fumes have ceased to be evolved, which will be in about two minutes, replace the cover glass and run in cold water as fast as possible, using a tip with at least a 2-mm. opening, care being taken to hold the tip several inches from the casserole; at first shooting the water in a little at a time until the most violent action is over; then dilute to 50 c.c., boil well for five minutes to get all the iron salts in solution. If lead is not desired on the same sample, it will be sufficient to boil for two minutes.

Filter into a 250-c.c. beaker containing a piece of sheet aluminum bent at right angles; wash the casserole and precipitate twice with hot water; add one to two drops of 1:1 hydrochloric acid to the beaker containing the copper; cover and place on hot plate. The addition of the hydrochloric acid will greatly increase the speed with which the copper is plated out, due to the fact that the ferric salts are more quickly reduced by the liberation of hydrogen from the reaction between the aluminum and hydrochloric acid. Hydrochloric acid is regenerated as fast as used. The hydrochloric acid will also precipitate any appreciable amount of silver which may be present, thus eliminating a source of error in titration.

When the aluminum is clean, or the solution clear, remove from the hot plate; filter through an open filter (black label No. 589), taking care to keep as much of the copper as possible in the beaker; wash off the aluminum and put it on the filter rack; wash the copper on the filter into the point and wash the copper in the beaker, by decantation, twice with hot water. Place the beaker containing the copper under the funnel; stand the aluminum on edge in the funnel and pour 3 to 5 c.c. of hot nitric acid (1:1) over the aluminum and filter paper; wash both well; cover the beaker and place on hot plate and heat until all the copper is dissolved; add bromine water until the solution is slightly colored; boil off the excess, remove from the hot plate; add 1 c.c. excess ammonium hydroxide, and by placing a stirring-rod in the beaker the excess of ammonia may be boiled off with less danger of bumping. Add 2 c.c. excess strong acetic acid to the boiling solution; boil for one or two minutes in order to be sure any basic salts of copper are in solution. Remove from the hot plate; take off cover glass; dilute with cold water to 40 c.c. and place the beaker in a cooler. Titrate when cold with thiosulphate which has been standardized against C. P. copper (1 c.c. equals 1% for half a gram sample), using potassium iodide and starch

Mexican Pig-Iron Industry

By H. M. Wolcott

The only important manufacturer of pig iron in Mexico is the Cia. Fundidora de Fierro y Acero, of Monterey, Nuevo Leon. The anual report of this company for 1911 states that its output of pig iron for that year was 71,337 tons, an increase over 1910 of 26,246 tons. While the pig iron generally produced in Mexico is somewhat soft, and consequently has to be mixed with foreign irons to make a satisfactory casting, it is said that the iron manufactured by the Monterey plant is as good as that produced in the United States or other countries, and that the company does not find it necessary to mix foreign irons with its output. In the fiscal year 1910-11 2681 metric tons (metric ton = 2204.6 lb.) of pig iron, valued at $46,672, were imported into Mexico, supplied by the following countries: Great Britain, 1963.6 tons, value $33,173; United States, 663.2 tons, value $12,236; Germany, 38.6 tons, value $825; China, 15.1 tons, value $351; France, 0.5 ton, value $87. The duty assessed by the Mexican Government on imported pig iron is: On iron in ingots of first fusion or in filings or scrap, ₱0.02 per gross kg. (equivalent to about 0.45c. per lb. avoirdupois); on iron, roughly wrought (bar) in ingots, and steel in ingots, ₱2.50 per 100 gross kg. (about 0.56c. per lb.). In addition to this duty a surtax of 5% is assessable under the provisions of the Mexican budget law of June 3, 1912.—*Daily Consular and Trade Reports.*

Cost of Mt. Lyell Copper

During the half-year ended September 30, 1912, the revenue of the Mt. Lyell company from sale of copper and superphosphates, and from railway traffic was $1,565,337, the total working cost being $825,528 divided as follows:

	Per ton.
Mining 155,243 tons	$2.33
Mine preparatory works overburden account—50c per ton on 21,523 tons of open-cut ore raised during half-year	0.07
Mt. Lyell mine underground development account—8c. per ton on 74,724 tons of ore mined underground	0.04
Smelting expenses, 157,296 tons of ore	2.10
Converter expenses (bessemerizing)	0.25
Freight and charges on copper	0.59
Total per ton of ore	$5.38
Office expenses, prospecting, taxes, and depreciation	$0.92

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

American Institute of Mining Engineers

The Editor:

Sir:—The Land Fund contributions continue to come in. The Fund now reaches, in cash and promises, over $35,000. The number of replies received in response to the invitations to contribute which I sent to our membership, does not really exceed ten per cent. If the indifference arises from any feeling, to the effect that the recent discussion with regard to the past administration of the Institute is likely to lead to its disintegration, I am sure that dread may be dismissed.

I think we have to regard the development of our great educational institutions in the same light as we do our great industrial and mercantile corporations. The day of individual activity has passed, but, at the time that these institutions were dependent upon the energy and activities of an individual, it was the only way they could have been carried on. Their prosperity today is due to the unselfishness and willingness of the individuals, who laid the foundation for future prosperity, and built the first or second stories of the structure to which today story after story is being added by co-operative energy instead of individual energy. Without Dr. Raymond's help in the past the Institute would not be what it is today; but the past is past, and the Institute at large, recognizing that fact, is adopting a different organization and a different system of management. We know, in the commercial world, that the changes from the old system have brought about litigation, heartburning, more or less injustice, and many other causes of discontent and dissatisfaction; and the changes which we have all been trying to bring about in the Institute have not been devised, and will probably not be carried into effect, without hurting somebody, and without the exercise of more or less forebearance and willingness to forego one's particular notions, and yield to the will of the majority. There are among us in the East floating rumors of rabid discontent and threats of destructive nature on the part of the Western members. We hear talk of starting an opposition institute in the West, and of the intention of publishing and ventilating the original report of the Committee of Five which, as originally written, was a mere suggestion, never adopted by the majority of the Committee, never accepted by the Board, and which therefore is to all intents and purposes a private document, which it would be of course a breach of courtesy to publish. I cannot think that the above is really the attitude of the great body of the Western members.

Last year, under Mr. Kirchhoff's administration, and this year under Mr. Kemp's, radical steps have been taken toward so altering the constitution and the administration of the Institute that the members at large shall take a deeper interest in its affairs, and all co-operate, through local sections, in increasing the volume, without diminishing the quality, of the scientific literature which has made our *Transactions* famous the world over. The method of organizing the excursions in the past may be open to criticism. That is a matter of difference of opinion; but, forgetting the things that are behind us, let us look forward to the duties that lie ahead of us in the future, and co-operate to create harmony and infuse enthusiasm into our membership. My share of the work has been to try to raise the fund necessary to pay off the balance due on the Land Fund, and thus avoid the raising of the dues. We draw our membership in great measure from the salaried officers, not from the capitalists who employ them, and I know from experience that $5 or $10 is to some men at some period of their lives a sum of considerable importance; and therefore personally I have been extremely anxious to avert, if possible, an increase in membership dues, and I believe that I shall succeed.

JAMES DOUGLAS.

New York City, January 10.

Labor and Social Progress

The Editor:

Sir—I am sending you these lines expressing the views of enlightened workmen concerning the 'ill advised' strike at Bingham and Ely. In your editorial of November 2 you stated that nothing was gained for the men other than what might have been obtained by peaceful means. If we are to believe the *Press*, the strike was a peaceable one, but you say that peaceable means might have obtained equal results. Does stopping work mean warfare? There is much room to doubt that the small gain granted the men would have been obtained had no concerted action through their organization been taken. Such steps for bettering the conditions of the worker are not in line with the policy carried out by the combinations domineering at these places. That the wage scale was not advanced when copper was 16c. last May proves that pressure was necessary. The outcome at Ely and Bingham does not "indicate the futility of syndicalism," as you say, but the lack of it. Syndicalism we are not in favor of, but it is plainly evident that causes for its existence are everywhere present in embryo and it is only a matter of time when our country will be beset with conditions similar to those in England last spring. But this more or less formidable expression of our economic interest will disappear when the cause for its existence shall have disappeared, which is the aggressions of capital.

You say, "the demand for higher wages based upon the increased profits" will to many minds, "present a degree of reasonableness" (it certainly will), but if such a principle is to be admitted, then the way is open to a corresponding reduction of wages when profits are smaller. Is not this principle everywhere carried out? Do not the industries shut down periodically and make tramps of us? Are we not in want during depressions? Are we not forced to curtail our consumption of utilities because of

our over production of commodities? We live so long as we find work and find work only when our work increases capital. This is just dawning on his majesty, the American laborer, and our 'leading gentlemen' may expect a change by virtue of this awakening.

You argue thus, "the line of progress in industrial development is steadily toward the stabilizing of the conditions of the workers, who are less able to bear reverses than the men who employ them." Certainly, but how can we stabilize conditions in a society founded on the antagonisms between the producing non-possessors and possessing non-producers, on the one hand, and on the other the anarchy of production? "Any program of betterment for the wage-earner which overlooks this fundamental principle cannot lead to ultimate success." The action of the men in raising their standards of living will do much toward the stabilizing of conditions and is therefore in harmony with "this fundamental principle" which will lead to "ultimate success." The reason the conditions are so unstable now is because they are too stable. In other words, society will have to go through a period of great social unrest in order that it may be taught how to rid itself of its antagonisms and have social rest.

Syndicalism is a splendid weapon for wresting the means of life from the exploiters of labor, but it has one great drawback—it will not work. We cannot remain with hands folded long enough, which proves the futility of the movement. It is hoped that the profession will give the labor question the serious consideration that it merits. History teaches us that it is a dangerous one to ignore. Should our very best citizens continue to ignore fundamental conditions and stupidly attempt to stop economic development, bloodshed will be inevitable. Except for your facts and logic, your argument is a good one.

A Laborer.

Long Beach, California, December 15, 1912.

[In a journal devoted to technology such as this, it is commonly impossible to afford much space to the discussion of social problems. But our correspondent's letter is, except for the profitless quibble with which it opens and the empty innuendo with which it concludes, so interesting and so expressive of one view-point of the matter that we are glad to accord space for it and for necessary comment as well. For useful discussion of social problems, however, it is necessary to have a certain measure of agreement upon fundamentals, and to one who believes that modern society is "founded on the antagonisms between the producing non-possessors and the possessing non-producers" our remarks appear in much the same light that a discussion of the prophylaxis of typhoid fever would to a Christian Scientist. In our view any discussion of social problems based on the belief that the *entrepreneur* and the laborer are natural enemies is as unlikely to lead to right conclusions as a system of hygiene which supposes that the hands are the natural enemies of the feet because the feet are obliged to carry them about and are clothed in harsh cowhide while the hands wear soft kid. In both cases the parts of a whole organism have different functions to perform and may perform them badly or well and the difference in functions indicates a necessary coördination rather than a basal antagonism. In plain words, the laborer cannot find a 'job' unless an *entrepreneur* has started a business to employ him; nor can the latter carry on his business unless there are laborers to do the work. The circumstance that the *entrepreneur* engages in business to secure a profit from the utilization of his capital, and the less he pays his laborers the greater will be his profits, does not indicate that capital and labor are fundamentally antagonistic, for similar relations characterize every phase of human life. The workman is paid a certain sum for 8 hours' work; the less work he does in that time the higher his rate of pay per foot pound of energy expended. Or, if the company boards him, the more food he eats the more he gets for his labor. But if he eats more food than his system requires, he will suffer rather than profit from taking it; if he does too little in a day he will be dismissed; and if an employer pays his laborers less than a proper wage for the service performed he will suffer through being unable to secure the best class of workmen, or perhaps even a sufficient supply of any quality. Such relations are semi-automatic, but their failure, through the complexity of relations, to completely and immediately adjust themselves easily, leads to wrong conclusions. The proper wage for any given service varies from year to year, but readjustment is not immediate and complete because that is impracticable in the conduct of business. The apprentice who starts in at $10 per month does not get $10.25 per month as soon as he has learned a little; his first increase is probably to $15 per month. His service was not worth $10 during the first month, later it was worth more, but from a business standpoint it was not practicable to adjust service and recompense more exactly.

Stabilizing conditions for the wage worker is an outgrowth of fundamental characteristics. The workman renders a fixed service for a fixed return, the *entrepreneur* risks his capital and energy to secure a variable profit which may be larger or may be negative, a loss, in other words. He pays his laborers whether he makes a profit or not; in other words he carries the risk incident to carrying on the business. If there is a loss he shoulders it; if there is a considerable profit he is entitled to it as a return for the risk incurred. Where the return to the laborer is contingent upon the profit or lack of it resulting from his work, he ceases to be merely a laborer and becomes in some degree a partner in the enterprise. This is not, despite the widely held views to the contrary, a desirable relationship, because the profit which does or does not accrue does not depend in most cases upon his efforts. For example, a drummer properly receives a commission upon the sales he makes, because he directly influences them, the workman who made the article does not get a commission upon sales because his influence upon them is negligible. On the contrary the workman would properly object to having the recompense for his work depend upon the results secured

by someone over whom he has no control. To be specific, a miner has no claims whatever upon such increased profits as a copper mining company may derive through management. He may properly demand increased wages when there is a rise in the general level of the commodity prices; but there is no fundamental logical, or moral ground upon which to base a demand for increased wages where, through a temporary rise in the selling price of its product, the company which employs him makes increased profit. In certain industries the employer has gone to his employees with a request that they help him carry his loss by accepting lower wages in order to tide him over a period of loss. The laborer thus becomes in a sense a partner in the enterprise, and it may be to his advantage to do so, for otherwise the employer may be forced to close down and the laborer be thrown out of employment. But any such arrangement as this or the others mentioned complicate the clear cut relations between the employer who takes the risk of his enterprise and the laborer who assumes no risk, but sells his labor for a stable price. The employer is supposed to possess sufficient reserve to tide him and his business over periods of no return; the employee possesses little or no reserve and the line of progress in modern development has been to stabilize conditions for the workingman, so that periods of stress may be minimized. In Japan, for example, some of the mining companies sell rice to their employees throughout the year at a fixed rate which is often materially lower than the average market rate, which fluctuates greatly between one harvest time and the next. The slight financial loss to the company is charged to wages account and brings more than a corresponding degree of comfort to the miners. Large companies in America frequently maintain stores at which goods are sold to employees at a small margin above cost-price to prevent their being exploited by local merchants, and an Australian company has recently opened a butcher shop for the same purpose. Compulsory compensation of workmen for accidents is in process of becoming established by state legislation throughout the Union and a number of large companies have made arrangements for the pensioning of aged employees. In England national insurance against ill-health for all employed persons, and insurance against unemployment in certain callings, has recently been put in force.

Right conceptions of communal relations grow slowly and provision for the support of the dependents of deceased wageworkers, and similar devices to give to the honest worker an assured steady income and as large a degree as possible of protection against reverses of fortune are yet in the future. Progress lies in this direction and not in syndicalism. The strike at Bingham and Ely was ill-advised because it was in a large degree an attempt to secure from the operators recognition of the Western Federation of Miners, and in our opinion, the increase in wages finally obtained could have been secured by more peaceable means than the calling of a general strike. The Western Federation of Miners has proved itself unworthy of recognition. The rank and file of its members, honest, hard-working men, have been dominated by a coterie who have directed the policy of the organization along lines that are not only stupid, but have been at times, ignorant, vicious, and criminal. For the enemy of society we have no sympathy, whether he wear tailor-made suits or overalls.

Neither has society "to go through a period of great social unrest in order that it may be taught how to rid itself of its antagonisms and have social rest." This is often more violently expressed by labor agitators, who declare that only terrorism will be effective in securing an adjustment of present social problems. This is the reverse of truth. At no time in history has the voice of labor commanded more attention than at present and at no time have the needs of labor been more considered. One hundred years ago large numbers of men throughout the world were living in slavery. Last week, with the final freeing of the Russian serfs, legalized slavery disappeared from the civilized world. Living conditions for rich and poor have been growing better and those who declaim that "the rich are growing richer and the poor poorer" know not the facts of the case. The poverty of the slums of New York and Chicago is affluence compared with the poverty in China and India, though by the great increase in wealth and comfort throughout our country it may seem more bitter than a few decades ago when the Sunday newspapers were fond of listing the few people in the United States who were worth over a million dollars. Social unrest similarly seems more serious today when pot-house oratory is scattered broadcast by the aid of the printed page, and the rascals, who in former years would sulk into an alley to 'slug' the foreman, are able with a few pounds of dynamite in an instant to involve lives and property in wholesale destruction. We believe in labor unions, we applaud the efforts of laboring men to better their condition, but for violence and criminal methods, whether employed by rich or poor, we have only condemnation. Much progress has been made and the rate is more rapid than at any previous time. The outlook is bright and perhaps its most discouraging future is that so many intelligent men among the workers show themselves possessed of so little real insight into the true factors of social problems.—EDITOR.]

Flotation Patents

The Editor.

Sir—In your issue of December 28 last you published a letter from Jacob D. Wolf under the heading of 'Flotation Patents.' For the information of those who may have read Mr. Wolf's letter, and speaking for Minerals Separation, Ltd., I am instructed to say that Mr. Wolf's statements are wholly false and his assertions ridiculous. In the last paragraph of his letter he threatens the company with litigation, and therefore the board of directors of Minerals Separation, Ltd., has instructed Henry D. Williams, of 76 William street, New York City, to accept service on behalf of Minerals Separation, Limited.

EDWARD H. NUTTER.

San Francisco, January 21.

Official Ballot of the American Institute of Mining Engineers

Officers and members of the council under the present constitution: President, Charles F. Rand, New York. Vice-presidents, C. W. Merrill, San Francisco; T. H. Leggett, New York; J. A. Holmes, Washington. Councillors, H. L. Smyth, Massachusetts; F. W. Denton, Michigan; E. V. d'Invilliers, Pennsylvania. Secretary of council, Bradley Stoughton, New York.

Directors and officers under the new constitution: President, Charles F. Rand, New York. Past-presidents, Charles Kirchhoff, New York; James F. Kemp, New York. Vice-presidents, Sidney J. Jennings, New York; George C. Stone, New York; B. B. Thayer, New York; C. W. Merrill, San Francisco; T. H. Legget, New York; F. W. Denton, Michigan. Directors, W. L. Saunders, New York; E. V. d'Invilliers, Philadelphia; C. S. Robinson, Youngstown; R. W. Brock, Ottawa; H. L. Smyth, Watertown; Walter H. Wiley, Los Angeles; J. A. Holmes, Washington; J. J. Ormsbee, El Paso; J. W. Finch, Denver; J. W. Richards, South Bethlehem; J. W. Malcolmson, Kansas City; H. V. Winchell, Minneapolis; Stanley A. Easton, Kellogg; E. P. Mathewson, Anaconda; G. G. Crawford, Birmingham; L. D. Ricketts, Cananea. Directors (to fill the unexpired term of Messrs. Rand, Stone, and Kemp), R. W. Hunt, Chicago; James Gayley, New York; R. V. Norris, Wilkes-Barre.

Directors from the old board who will fill their unexpired terms in the new board in accordance with the new constitution, James Douglas, J. F. Kemp, A. R. Ledoux, E. B. Kirby, C. F. Rand, and G. C. Stone. Vice-presidents of the Council holding over, Karl Eilers, Waldemar Lindgren, B. B. Thayer. Councillors holding over, A. E. Carlton, W. J. Oleott, E. L. Young, John H. Janeway, Jr., Sidney J. Jennings, Joseph W. Richards.

Platinum-mining will be undertaken by the Ovsyankin Company of the Urals, which has just been formed of purely Russian members. This company controls 109 placers in the Orenburg Government, some of which have been carefully investigated and are being exploited by *staratelli* (free laborers). This company expects to be able to start three of its gold-washings and refineries on the ground. Generally speaking, all over the gold district there is feverish activity in both surface and underground work.

During November the 40-stamp mill of the Abosso Gold Mining Co., Ltd., in West Africa, treated 9100 tons, yielding $81,000, at a cost of $6 per ton, the net profit being $16,000. The Taquah Mining & Exploration 30-stamp mill treated 5460 tons, yielding $76,000, at a cost of $8.30 per ton, net profits being $21,000. The Ashanti roasting and cyanide plants treated 13,839 tons, worth $202,000, with a profit of $80,000.

Graphite exported from Korea to Japan in 1911 amounted to 131,044 tons, valued at $65,885.

Special Correspondence

NEW YORK

DECLINING COPPER MARKET. — ALASKA GOLD MINES. — IRON MINES IN CHILE.

Recent developments in the copper situation have been most interesting. Ever since November, when the price was pegged at 17¾c. per pound for refined copper, consumers in this country have been assuming more and more of a determined attitude, and have been subsisting upon such purchases as were sufficient only for immediate needs. This position was further and greatly strengthened by the December figures of the Copper Producers' Association, showing a gain in accumulated stocks of refined copper of approximately 20,000,000 lb. The strength of the various interests in control of the copper metal market, without regard to the distinction as to whether they may have been working in harmony by mere coincidence or by express agreement, seemed to be invincible, yet this group of moneyed interests has seen fit to make, within the past few days, some very marked concessions, and evidently the retreat is not yet ended. Copper metal has been marked down from 17¾ to 16½c., and even this concession has obviously failed to bring domestic consumers into the market. The present controlling groups are without question too strongly intrenched and too completely in touch with all phases of the situation to allow themselves to suffer any such disaster as has overtaken from time to time the various former attempts to control the market in copper metal. It is worth while, however, to note the various factors which brought about the 'pulling of the peg.' It was not alone the addition of 20,000,000 lb. of copper to the existing surplus; it was also the knowledge that stocks of copper were and are held at the refineries, an element of which the strength could only be estimated by the consumer. There was also the new copper, which in large part failed to make itself felt during the past year, but which will be a most important addition during the twelve months to come. Federal investigations have also come to be recognized as serious matters and not to be lightly invited. What weight may have been given to a possible investigation can, of course, be but matter of conjecture. At any rate, the manufacturers have proved themselves victorious in the stand they have taken, and are now vigorously pressing for further concessions.

As might have been expected, the tendency of copper shares was downward under the influence of the metal market. The exceptions which deserve to be noted were Greene-Cananea, upon the hope of better conditions in Mexico, and Trinity copper, the latter advancing on reports of successful tests of the Bradley process made at the Washoe smelter, which process, it is said, will be installed at the Trinity's mines and, it is hoped, will permit of active operations. The Mines Company of America reports that conditions in the localities surrounding its various properties have so far improved that all of its mines are now in full operation. In spite of the various and sundry troubles encountered during the year, a gross production during 1912 was achieved of $2,400,000, from which a net profit was made amounting to $600,000.

The Homestake Mining Co. of South Dakota has gone its wonted way so long and at so steady a pace, paying regularly 50c. per share monthly, that it comes with something of a sense of surprise to note any financial operations of the company outside of the regular routine. It is now announced that the company is to capitalize expenditures made out of earnings, during the past seven years, for replacements, betterments, and additional property, to the extent of $3,116,000, which stock increase, if ratified by the shareholders, is to be distributed in March in the form of a 15% stock dividend. In the meantime the regularly monthly dividend of the company has been increased from 50c. per share to 65c. per share.

The shares of the Alaska Gold Mines have been the feature of the outside market in the mining list, and bid fair to

prove proportionately as profitable as Chino copper, which was also a Hayden-Stone underwriting. A recent statement put out by the latter is to the effect that it has been fully demonstrated from the operations of the old mill that 75c. per ton is an ample estimate for mining and milling the ores. It is also stated that the 6000-ton mill which is to be erected as quickly as possible is to be but the nucleus of the milling plant with which the property will eventually be equipped, and that a capacity of 20,000 tons per day will in all probability be provided as quickly as the ground can be put into shape to furnish the ore.

Theodore Dengler has been appointed to the vacancy made in the staff of the Mohawk and Wolverine mining companies by the resignation of Fred Smith, who was superintendent of these two companies for many years. Mr. Smith is known throughout the Michigan copper country as one of the old-fashioned mining superintendents who kept in close touch with his men, a large number of whom, now employed by the Wolverine, went with him when he went into the employ of that company in 1890.

As a checkmate to the recent acquisition of a large body of iron ore lands in Brazil, by a group of English and American financiers, Charles M. Schwab, of the Bethlehem Steel Co., of Pennsylvania, has recently returned from Europe after having completed the purchase of a large tract of iron ore land in Chile. The property is known as the Tofo iron mines and is said to contain 100,000,000 tons of very high-grade iron ore. Mr. Schwab states that he contemplates building a fleet of at least ten vessels to begin with, to carry the ore from the mines at Coquimbo on the Pacific coast through the Panama canal for eventual delivery to the plant at Bethlehem. It is expected that the ore can be carried from mine to vessel by an aerial tramway.

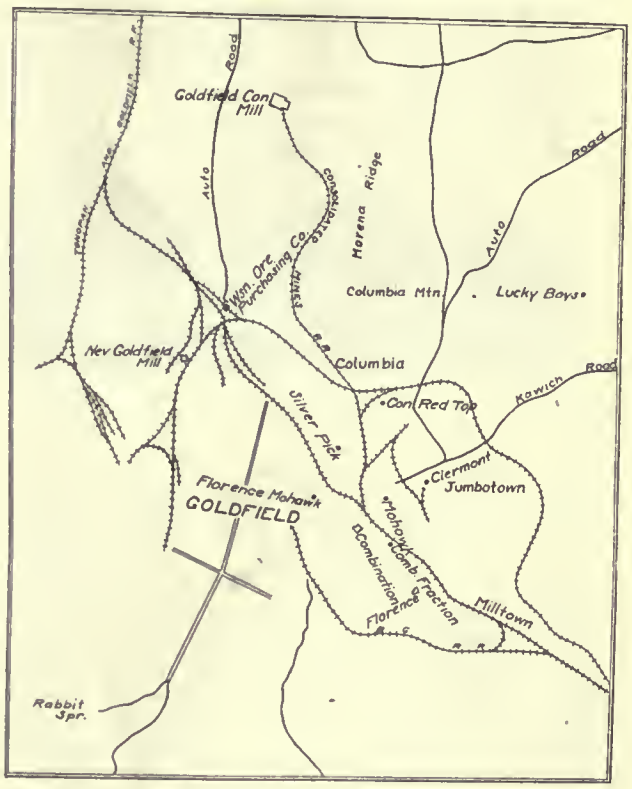
GOLDFIELD, NEVADA

NEW ORE IN COMBINATION.—WORK AT JUMBO.

In the Combination mine of the Goldfield Consolidated, an orebody has been discovered, development upon which, on the 130-ft. level alone, is estimated to have added $500,000 net to the visible ore reserves of the company. This ore was found immediately under the engineering office, northwest of the Combination shaft, and in what has been known as the foot-wall country that has been pronounced barren by some supposed authorities. The ore is shown by development to be an extension of the Combination 'glory-hole' orebody, from which a large tonnage of rich, free-milling ore was produced. Officials of the company say that at one point this ore is 40 ft. wide and the entire mass will average $25 per ton or better. The value of the discovery may prove much greater than indicated by this estimate, as no attempt has yet been made to cut the ore-shoot, either above or below the level on which it was first opened. During the past year the energies of mining companies in the Goldfield district have been devoted almost altogether to preparatory and dead work, shaft-sinking and exploring or prospecting. This year a large amount of development work will be done, and much of this will be at from 1000 to 2000-ft. depth. Work below the 1000-ft. levels of the Consolidated and Merger mines has already demonstrated the extensive fissuring of the rock that had been held by many to be the limit of enrichment at depth, and the operations planned should, within the year, determine with some degree of accuracy the value of the territory under development.

An agreement entered into during the week between the Atlanta Mines Co. and the Goldfield Merger Mines Co. provides for the immediate sinking by the Merger company of its main or St. Ives shaft to a depth of 1750 ft. and for driving a cross-cut at this depth to the boundary of the Atlanta. At this point the Atlanta will assume the development of its own ground, working through the Merger shaft, and this work is to be done with all possible expedition. A sinking pump has been ordered, of ample capacity to handle any flow of water that may develop. The present hoisting capacity of the Merger is ample to work both properties, and the pumps lately installed in the St. Ives shaft are capable of raising all the water reaching the shaft from the 1330-ft. level to the surface, the sinking pump raising it to the station sump on the 1330-ft. level. This constitutes a radical change from the tentative plans announced several months ago by the Atlanta directors, when it was thought that the better plan would be to open this ground from the 1400-ft. level of the Grizzly Bear mine. K. M. Simpson, the engineer in charge of the 'outside' Wingfield properties, has been named as general manager for the Atlanta company. The Merger shaft is now down 1400 ft. It is 7 by 18 ft. and is being sunk with the aid of air drills. Over 130 ft. has been made in a single month. The Atlanta company has $100,000 cash in its treasury.

Operations of the Jumbo Extension Co. are now upon a substantial profit-earning basis. The Polverde mine has sufficient ore developed, according to the company's engineers and management, to supply for a year at least the Bonnie Claire mill, 36 miles south of Goldfield, to which the mine is shipping from 90 to 100 tons per day. The



GOLDFIELD AND VICINITY.

mill was largely remodeled by this company, and the only process now employed is concentration, although there is a complete cyanide plant in connection with the mill. A recovery of 72 to 74% is obtained, and the concentrate is shipped to the International Smelting & Refining Co. at Tooele, Utah. Ore of better grade, refractory by reason of its content of silver and copper, is shipped to the sampler of the Western Ore Purchasing Co. and has averaged $60 to $85 per ton. On the 900-ft. level of the mine a diagonal cross-cut has exposed a 7-ft. face, assaying $350 per ton, but its extent is unknown, as the cross-cut is being driven ahead to prepare a sill for a raise to the intermediate level, and the twisted appearance of the vein at this point renders it impossible to determine the course of the ore, which is near an extensively faulted area. Stopes on the 800-ft. level are producing a good tonnage of excellent milling material, and a winze will be extended from the 940-ft. level on the rich ore-shoot to determine the best point to raise for the ore from the 1017-ft. level.

Extensive work has been started on the ground of the C. O. D. Consolidated by the Goldfield Mines Operating Co., which has secured a five-year lease embracing the Gold Bar and parts of the C. O. D. and Victor claims, and is working at the Gold Bar, Victor, and Florence-C. O. D. shafts. This work has begun since the first of the year, and already a body of good ore, 6 ft. wide, has been exposed on the

185-ft. level of the Gold Bar. The electric hoist formerly at the Sills shaft has been installed at the Florence-C. O. D. shaft, which was sunk by lessees on the flat below the Gold Bar. The work is under the direction of G. C. Webb.

MELBOURNE, AUSTRALIA

HAMPDEN CLONCURRY.—TWO BROKEN HILL MINES.—MT. LYELL.

Of all Australian mines, the Hampden Cloncurry, of Queensland, is perhaps the one which is at the present moment most generally regarded as having a first-class prospect before it. The past half-year has been one of great interest because it has marked the close of a prolonged construction campaign. Smelting was started by the middle of July, and it is expected that the first dividend will be paid in February next. The present capacity of the mine for production is shown by the returns for September, October, and November, which are as fellows: Ore, 12,932 tons; matte, 2125 tons; blister copper, 2117 tons; fine copper, 2096½ tons; gold, 1183 oz.; silver, 24,332 oz. The ore reserves are estimated at 238,000 tons, containing 24,800 tons of copper, and if the negotiations for the purchase of the Mt. Gregor Cloncurry mines be brought to a successful issue, the reserve will be considerably increased. The ore is chiefly pyritic, and is separated at the main shaft into fine and coarse for separate treatment. The smelting plant consists of two furnaces, the blast being supplied by two Bellis & Morcom vertical high-speed air-compressors, each capable of giving 6500 cu. ft. of air per minute at a pressure of 5 lb. per square inch.

Like most of the other big Broken Hill mines, Block 10 has had a very satisfactory half-year, owing largely to the high level at which the market prices of the metals have been standing. The new mill at this mine has been a great success, producing a concentrate rich in both lead and silver and making higher recoveries. The costs are: ore extraction, per ton milled, 15s. 2.59d.; development, 1s. 2.15d.; milling and treatment, 5s. 2.17d.; general expenses, 1s. 0.71d.; total, £1 2s. 7.62d., equal to about $5.48. There is, however, a fly in the ointment of the Block 10 company in that the present reserves are calculated to give only two years' supply for the mill, and the finding of any new orebody is beginning to be despaired of. In Block 14 the outlook is even worse. This mine is almost entirely dependent upon its carbonate ore, its only other reserve being between half a million and a million tons of low-grade sulphides. The mine has been so extensively bored that there can be little hope remaining of any discovery to prolong its existence.

Although the Mount Lyell Mining & Railway Co., Ltd., made a clear profit of over $500,000 during the six months ended September 30, no dividend has been declared, in view of the disaster at the mine that ushered in the current half-year. This has already involved the company in very heavy expenditure and is certain to involve it in much greater, for a Government commission is now beginning to inquire into the cause of the outbreak of fire in the mine workings, and, even if the company be acquitted of blame, the cost to it will assuredly be considerable, while, if it be found in any way blameworthy, it will doubtless be mulcted in very heavy damages and for compensation to the families of those who lost their lives. Apart from this unpleasant feature of the position of the company today, it is noteworthy that, despite the improvement in the net profit, things are not going altogether satisfactorily. For one thing, the grade of the ore smelted is distinctly on the decline, though the estimate of the grade of the ore reserve has never been altered to match the decline. And, while the grade of the ore is going down, the costs of mining are going up. The working cost per ton of ore, as a matter of fact, fell slightly during the past half-year, but the reduction in the copper content caused a considerable rise in the working cost per ton of copper. The policy of the company in accumulating a reserve to provide for possible emergencies is therefore a wise one to pursue.

AUSTIN, TEXAS

THE BIRD MINE.—SALE OF THE BURRO.—ANCIENT MINES.

Development work upon the Bird silver mine, situated 12 miles east of Alpine, has been started by W. B. Phillips of Austin and James Lafarelle of Alpine. It is claimed that there is a large amount of rich ore upon this property and that it will soon be brought to a producing stage. Several new test shafts will be sunk and the extent of the orebody proved, preparatory to increasing the working force. Regular shipments of zinc ore are being made from the Bonanza mine, situated in the Quitman mountains, two miles from Lasater station, on the Southern Pacific, west of Alpine. This ore runs from 40 to 44% zinc and the shipments are made to smelters in Kansas and Oklahoma. Operations upon this property are to be upon an enlarged scale early in the coming year, it is stated. A. M. Turney, of Alpine, has leased from W. W. Turney and A. M. Caruthers, for a period of 25 years, the Caruthers silver and lead mine, situated 10 miles east of Alpine. Some development work has been done upon this property, and ore that netted $80 per ton was shipped. Recently an examination of the mine was made by engineers, and they made a highly favorable report. Mr. Turney will put a large force of men to work developing the mine.

The Burro mine, situated near Etholene, in the Quitman mountains, has been purchased by the Southwestern Mines Co. This property was formerly owned and operated by Messrs. Owen, Nichol, and Briggs, and considerable gold ore was shipped. It has been inactive for some time. The new owners are now cleaning out the old workings and will install a steam-hoist and other modern equipment, preparatory to resuming mining operations. J. R. Harper, A. P. Coles, and Lewis W. Smith, all of El Paso, own a promising copper claim, situated 15 miles north of El Paso, which they are now developing. The shaft is now down about 75 ft., and a hoisting plant will soon be installed. Considerable importance is attached in mining circles to the recent discovery of ancient Spanish workings in the Quitman mountains near Etholene station. These old mines were brought to light by a cave-in caused by a heavy rain. They are near the Lulu B. claims, which are owned by William Crosby and son of El Paso. Explorations have been made of these ancient Spanish mines, and they are shown to contain very extensive workings. Mr. Crosby and his son are carrying on development operations upon their properties in that section, and it is expected that work will also soon be started on the ancient Spanish mines.

H. A. O'Neal, of Atlanta, Texas, as trustee for a syndicate of Philadelphia men, has signed a contract for the lease of the iron furnace and pipe works of the State of Texas, situated at the penitentiary at Rusk, and the first instalment of $1666 of the annual sum of $5000 that is to be paid the state under the contract has been paid. In addition to this lease contract, the syndicate is given permission to purchase iron ore from the state's holdings. The lease is for two years, with the option on the part of the lessees to extend the contract for an additional four years. The contract does not provide for the use of convict labor in the operation of the iron industry, but it is expected that what ore is mined from the state's lands will be done by convicts under the supervision of the penitentiary authorities. It is announced by Mr. O'Neal that the syndicate has already spent $250,000 cash in acquiring iron-ore lands in eastern Texas, and that an additional $20,000 will be spent in improving the plant at Rusk. Under the terms of the contract the furnace must be placed in operation within six months from January 12, 1913. The special purpose of the syndicate in leasing the state's iron furnace is to conduct extensive experiments with the view of determining fully whether the industry can be made profitable, and if the results are as satisfactory as are now expected, development of the syndicate's ore-beds on an extensive scale will be started. The operations of this syndicate are said to have no connection with the large iron-ore develop-

ment work that is now being carried on in Cass county, Texas, by Charles M. Schwab and associates.

JOHANNESBURG, TRANSVAAL

AVERAGE WORKING COSTS.—OUTPUT OF U. S. A.—COPPER PRODUCTION OF TRANSVAAL.

According to the usual analysis issued by the Chamber of Mines, the average cost per ton milled on the Rand for October showed a decrease of 5d. The cost in September was 18s. 8d. and for October 18s. 3d. per ton. A reduced cost of 2d. per ton was anticipated as a result of the cheaper freight rates on coal to the Rand, but to what extent the reduced cost may be due to this change, it is difficult to say. One striking feature of the October returns was that the lower costs were accompanied by a fall in the average yield of the ore sent to the mills of 7d. per ton, this being a repetition of former experience on these fields, where a higher yield has generally resulted in higher costs, and vice versa. The average yield in October was 28s. per ton, as compared with 28s. 7d. per ton in September and 28s. 9d., the highest average yield of any month of the year, in August. Owing to the reduced yield, the lower costs were not reflected in the average profit per ton milled, which in October was 9s. 10d. per ton, as against 10s. in September and August. Nevertheless, owing to the greater tonnage milled in October, the total working profits were £1,079,334, as compared with £1,040,820 in September, and £1,055,315 in August. The same 53 companies produced in October as in September, and this increase in the total working profits would seem to confirm the view that on the Rand higher total working profits can be more easily attained by milling large tonnages than by attempting to raise the grade unduly by artificial means; while as to the advantages of the former practice in the long run, there can be no two opinions. It is known that several mines have been milling ore of higher content than the average of the workable ore reserves, and to some extent the improvement in the average grade of the ore milled during 1912 is no doubt due to this. But it is clear that mines following this practice must in the end be left with a large accumulation of low-grade ore.

The returns issued by the Mines Department of the Union of South Africa give the total value of the mineral output of the Union (excluding diamonds) for October as £3,566,182. Probably if diamonds were included it would mean the addition of another £750,000, so that at the present the monthly mineral output of the Union of South Africa is well over £4,500,000, of which no less than £3,500,000 comes from the Transvaal. Gold amounts to no less than £3,268,927 of this huge total. The value of the October output was higher than any of the preceding four months, and, judging from the large area of the Far East Rand goldfield still untapped, it is probable that the output of gold from the Witwatersrand field will continue to increase for some time to come. Much, however, will depend upon the provision of adequate capital, for after the extensions and new developments of 1910 and 1911, there has been a comparative lull which will produce a corresponding lack of progress in the gold output for next year. There can, however, be little doubt felt that the Witwatersrand gold-mining industry must continue to expand in the future, and with the adoption of suitable mining methods the deep-level mines will be able to maintain their position for many years to come, despite the comparative low grade.

The value of the Transvaal output of copper in the month of October only amounted to £6130. But as there is only one copper mine working in the Transvaal, and that really developing in readiness for railway connection, present-day achievements are not any indication of the value of the copper prospects of the Transvaal. This mine, known as the Messina, is situated to the north of Pietersburg, and to the present the development results have shown the lode to average by assay 10%. Of this grade, about 170,000 tons of ore is already blocked out. The consulting engineer estimates that once the mill now under construction is completed and railway facilities available, the profit should be in the neighborhood of £240,000 per year. The outcrop of the lode was proved for a distance of nearly 4000 ft. along the strike, and the prospect of several producing copper mines being started in the neighborhood is considered encouraging.

LONDON

ORE SORTING ON THE RAND.—POSSIBLE ECONOMIES IN PRACTICE.

The decision of the metallurgists of the Consolidated Gold Fields of South Africa to abolish the sorting of ore at surface at Knights Deep, again draws attention to the relative advantages of close sorting as against handling a large tonnage of lower-grade ore. The extraction is only 17s. 5d. per ton milled, and the working cost is 11s. 6d. A few months ago the Simmer East was absorbed. For some time these mines have had a joint mill containing 400 stamps, 270 being used by Knights Deep and 130 by

RANDFONTEIN MILL.

Simmer East. The whole of the 400, together with 9 tube-mills, is now under one control and the plant now ranks as the fourth in size on the Rand. In October over 100,000 tons was crushed. There were only three other companies to exceed this figure: Randfontein Central, 217,089 tons; Crown Mines, 167,800 tons; and East Rand Proprietary, 148,500 tons. But from the point of view of gold output, Knights Deep ranked only eleventh, with £81,981. Four mines, the Ferreira Deep, Robinson, New Modderfontein, and Village Main Reef, exceeded this output, though treating less than half the tonnage. The monthly capacity is now being increased to 120,000 tons, by the addition of two more tube-mills. Sorting at surface has never been largely employed, but a great deal of waste has been employed for packing stopes. The width of the deposit does not afford much scope for surface sorting. At the Simmer East the ore is of different character, for the main gold-carrier is a thin and rich grit, and more harm than good is therefore done by sorting at surface. It is estimated that sorting to reject 3000 tons per month would cost £300, while the cost of milling it would be only £90; but this, of course, is not the real economic gauge. Figures show that as the average grade decreases, so does the percentage of waste rejected. Possibly the argument should be stated the other way round in some cases, though it cannot be doubted that in more cases, especially in deep levels, the ore is nowadays of uniformly low grade, and consequently the average content would not be substantially increased by more careful sorting. In looking through the returns by various companies, it is clear that the largest amount of sorting is done by the companies with the highest-grade ore. It will thus be seen that the abolition of sorting at a low-grade mine is not due to an unreasoning big-tonnage craze. The resident on the Rand is on the side of the big mill, the abolition of sorting, and the consequently prolonged life of the mines, having at heart the continued prosperity of the great South African community, rather than the interests of European shareholders whose only desire is to reap as big profits as possible in the shortest time.

General Mining News

ARIZONA

Gila County

The Miami mine produced 32,814,643 lb. of copper in 1912, at a cost of 9½c. per pound, which cost included a charge of 31c. per ton of ore to cover depreciation.

Recent developments in the Blackjack mine, on Lookout mountain one and one-half mile southeast of Bellevue, show that it may prove to be valuable. The ore is a conglomerate containing ruby and native silver, gray copper, gold, and galena. The mine has been opened by adits.

Maricopa County

The Big Blue property consists of 19 claims, containing copper and silver ore. E. V. Browne, of Los Angeles, and others have purchased the rights of a new chemical process of ore treatment and will erect a plant at the Big Blue. It will extract copper from carbonate ores, and treat 3% ore at a profit.

Santa Cruz County

At the old Alto mine, eight miles from Patagonia, lessees have opened high-grade ore which promises to be of importance. Mine timber and machinery have arrived for the Trench company, which is financed by Butte, Montana, men.

CALIFORNIA

Calaveras County

(Special Correspondence.)—On account of shortage of water and the extremely cold weather, which has frozen the small supply left, the Utica and Tuolumne power plants are out of commission. Consequently most of the mining properties furnished with power from these concerns are temporarily closed down. This county is experiencing the coldest weather in 30 years. H. A. Kuns, manager for the Waterman Mining & Milling Co., is doing some extensive prospecting on that property with a core-drill. It is understood that he intends boring numerous holes to a depth of 1000 ft. before sinking a shaft, which will require at least two years. This is an innovation in quartz mining, and is being watched with interest by large mining concerns. Mr. Kuns, besides being one of the principal owners of this property, is backed by Los Angeles capital. He also planned and built the power plant and 10-stamp mill for the Original Mining Co., operating a property on the Merced river. He introduced some original ideas in that plant which are proving successful. The consumption of power for this mill is not over 2 hp. per stamp of 1000 lb. Mr. Kuns is also the consulting engineer for the New Almaden Quicksilver Mining Company.

Angel's Camp, January 11.

Los Angeles County

(Special Correspondence.)—The annual banquet of the Los Angeles Chamber of Mines and Oil was held on January 24 in the new home of the Sierra Madre Club, on the top floor of the Los Angeles Investment building. The proceedings included formal installation of new officers and directors, interesting discussions on topics concerning mining and oil industries, and a good time generally. The banquet marks the close of the most successful year in the history of the organization.

Los Angeles, January 25.

Modoc County

At High Grade, the Gold Peak and Klondike claims were sold during the past week to B. Lawrence and others for about $10,000. These properties adjoin the Consolidated group.

Nevada County

(Special Correspondence.)—The 2200-ft. shaft of the Pennsylvania Mines Co. is to be sunk deeper, according to recent reports. On the 1700-ft. level excellent ore is exposed. The Pennsylvania mill is treating 70 to 80 tons of ore per day. The property is largely controlled by San Francisco people. Considerable work is under way at the Brunswick mine. Raising the new shaft from the old workings is progressing and it is expected to make connections in a few months. The new vein was sunk from surface several hundred feet, when a heavy flow of water hampered work. The pumps in the old workings are handling the water and the work of raising to meet the shaft is making good headway. It is understood a good reserve of milling ore is exposed. Tributers have worked several blocks of ground with excellent results. C. J. Mallen is superintendent. The Empire Mines Co. is operating along normal lines; 40 stamps are dropping steadily and good ore is being mined from a depth exceeding 2000 ft. It is locally estimated that the output of the property for the year approximated $750,000, although nothing of an official nature has been given out. Leaders in the local miners' union are making desperate efforts to bring delinquent members back into the fold. A large number of the men have become dissatisfied with the numerous assessments levied by the Western Federation of Miners and have refused to pay. Delinquents have been offered an opportunity to be restored

EMPIRE MINE AND MILL, GRASS VALLEY.

to full membership by making a nominal payment, but it is understood that the majority is showing no inclination of acceptance. Many of the miners openly declare they will pay no more assessments, unless local conditions warrant such levies. Grass Valley has long been a Western Federation stronghold, but for years the men have resented the levying of heavy assessments, and the outcome of the disaffection will be watched with considerable interest by the mining fraternity.

Grass Valley, January 7.

It is reported that good ore has been opened in the 2400-ft. level of the Champion mine. The Brunswick Gold Mining Co. is being sued for $20,000 by the widow of H. J. Cornelius, who was killed by fume in a raise from the 1250-ft. level. It is probable that the relatives of W. Nichols, who was killed with the other man, will also sue the company. The men were working on contract, and the company had to supply air at all times. Bad weather has interfered with drilling the gravel beds of Deer creek.

Sierra County

In the trial of A. L. Wisner and J. L. Meyers, at New York, charged with using the mails to defraud in promoting mining companies, it was stated that at the Empire mine it cost $63,000 to mine $20,000 worth of ore, and dividends were paid.

Trinity County

A snowslide at Trinity Center has swept away the stamp-mill of the Bonanza King mine. This cost about $50,000, and nothing remains save the 20 stamps, which are standing in place.

COLORADO

Gilpin County

The main shaft of the Pittsburg Extension is to be sunk several hundred feet below the 150-ft. level, where ore is worth from $80 to $100 per ton. A recent shipment of 6360 lb. of smelting ore yielded 1.49 oz. of gold, 22.24 oz. of silver, and 2.06% of copper, worth $37.09 per ton. A good deal of development and construction will be done at the Pazo

group in Nevadaville, this being the first of the old mines to commence work on the surface since the Newhouse tunnel was completed.

LAKE COUNTY (LEADVILLE)

The cold weather has caused a great deal of inconvenience here and snow has blocked the railroads. The aerial tramway of the Mt. Champion, Lackawana gulch, broke down again last week. The recent ore discovery in the lower adit is being explored, and is opening well. The main adit of the Winthrop Mining Co., English gulch, is being driven in white quartz and porphyry, similar to the upper workings. Lessees at the Belgian, Cucumber, La Plata, Moyer, and Snyder mines are busy, and prospecting is encouraging.

PITKIN COUNTY

This county showed an increase in silver, but a decrease in lead output in 1912. Several cars of zinc carbonate and sulphide concentrate were shipped from Aspen. Shipments of ore and concentrate from Creede showed a decrease for all metals except silver, which increased about 200,000 ounces.

TELLER COUNTY (CRIPPLE CREEK)

One of Cripple Creek's greatest utilities is the electric-power supply of the Arkansas Valley Railway, Light & Power Co., which was formed about a year ago and is controlled by Chicago people. Its combined plants furnish light and power in Pueblo, Canon City, and other towns about the Arkansas valley, and all the Cripple Creek district. About 15,000 hp. is available, generated by a water-power plant at Skagway, near Victor, and a steam plant at Pueblo and Canon City. There are about 100 electric hoists at Cripple Creek, and are much in favor among the smaller mines. All the mills are electrically driven, the Portland using 1400 hp., and Stratton's 1100 hp. The cost of power per ton treated varies from 5 to 10 cents. Two large electric pumps were recently installed at the 1600-ft. level of the Golden Cycle mine. Air is sold in the district for $2.50 per drill-shift for a 2¼-in. machine, while air from electrically-driven compressors will average $1 per shift.

The Vindicator Consolidated Gold Mining Co. will pay a dividend of 3c. per share, totaling $45,000, on January 25, making the amount paid to date $2,497,000, from a gross output of $10,000,000. The annual meeting is to be held shortly. Development of the north and south vein systems on the 1500 and 1600-ft. levels has been satisfactory. The company and lessees ship about 100 cars of ore per month. O. Shatz and Denver associates, leasing on the 1100-ft. level of the No. 1 shaft of the Vindicator, have opened 5 ft. of rich ore on No. 2 south vein. In the vein is a streak of nearly solid sylvanite.

The Kavanagh mill is treating 65 tons of ore per day worth $2 per ton, and a profit of $1000 per month is made. This plant cost about $25,000, the ore being crushed coarse and then leached with cyanide solution. The last pay-day at Cripple Creek meant a distribution of $315,000, and banks kept open for convenience of miners and others.

IDAHO

BEAR LAKE COUNTY

The phosphate industry of this state continues to increase slowly, with an output of 5000 tons from the Waterloo mine at Montpelier. Progress is retarded by high freight rates, litigation, and other troubles. A large supply of the rock is said to exist in the southeastern counties.

BONNER COUNTY

(Special Correspondence.)—Louis Duquette, a promoter and stockholder of the Idaho Gold & Radium Co. of Leonia, Idaho, states that work has been temporarily suspended on his properties on account of some litigation pending, but he expects to be able to resume development work in the spring. This is the company which created a sensation last spring by the discovery of pitchblende.

Leonia, January 12.

SHOSHONE COUNTY

The district court at Wallace, on January 18, gave a decision in favor of the Ontario Mining Co. in the case brought against it by the Stewart Mining Co., as mentioned in these columns last week. In his verdict the judge said, "there may be some little dispute about the apex of that vein, but there is no question in my mind as to its course, and there is no question in my mind as to the law of the case." F. A. Heinze's attorneys gave notice of appeal.

MONTANA

LINCOLN COUNTY

(Special Correspondence.)—It is rumored in Troy that the Banner & Bangle Mining Co., better known as the B. & B. company, has purchased the controlling interest in the Big Eight mine near Troy. The B. & B. mine is owned by the Greenoughs of Spokane, and has been worked steadily since spring. E. McCafferty, of Spokane, has been working the Big Eight under lease, and has had the lease extended for two years more.

Libby, January 12.

MADISON COUNTY

(Special Correspondence.)—The Montana-Illinois Copper Co. expects to have its property on South Boulder creek on a paying basis before long. The property has been recently equipped with a concentrating mill, which will be placed in operation next summer.

Virginia City, January 13.

SILVERBOW COUNTY

Preliminary estimates of the 1912 production of the East Butte mine show 14,765,170 lb. of copper, 361,060 oz. of silver, and 16,852 oz. of gold. By next March the mill should be treating 500 tons of ore per day. An increase of 80% in the furnace capacity has been decided on. The main shaft of the Butte & London is down 1130 ft., and is to be sunk to 1030 ft., and at 1600 ft. a cross-cut will be driven right across the property a distance of 2500 ft. The north cross-cut on the 2800-ft. level of the North Butte has cut the Snowball vein, showing 8 ft. of ore worth 8% of copper. Water is flowing fairly strong. On the 2400-ft. level this vein is nearly 50 ft. wide, 6 ft. of which is high grade.

At the Davis-Daly mine, during the past year, development has been actively carried on in all directions from the Colorado shaft in the eastern half of the ground, and in the western portion by cross-cutting from the West Gagnon workings of Anaconda. The Colorado shaft has been sunk to 2000-ft. depth. No. 12 vein gives the same good ore on the 2000-ft. level as that stoped above. From development on this level, 60 to 80 tons of ore per day has been produced. Lessees on the property have maintained a steady production.

The Tuolumne company is cross-cutting on the 2000-ft. level, and indications are favorable. On the 1600 and 1800-ft. levels development has not been encouraging. About 150 tons of ore containing 10% of copper is shipped daily to the Washoe smelter. During December the output was 2,763,570 lb. of copper, 131,146 oz. of silver, and 259 oz. of gold.

NEVADA

ESMERALDA COUNTY

The Goldfield Merger Mines Co. has shipped its first carload of high-grade ore to the local sampler of the Western Ore Purchasing Co. This ore came from the Velvet claim, and the drift on the 800-ft. level which is being driven from the Polverde mine of the Jumbo Extension Co. Preparations have been made at the Florence to complete sinking to 1270 ft., and cutting out a station at 1200 feet.

HUMBOLDT COUNTY

At a depth of 40 ft., the vein has been cut by an adit in the Weaver claims of George Wingfield at Rochester canyon. This proves a continuation of the rich vein from which J. Nenzel mined his ore in December. An ore-shoot has been uncovered on block 6 of the Crown Hills and traced for 100 ft., with a width of 16 to 30 in. Samples have given by assay 112, 139, 63, 110, and 5160 oz. of silver; and 0.10, 0.20, 0.10, 0.25, and 0.04 oz. of gold, respectively. Roch-

ester ore is similar to that of Tonopah in the proportions of silver to gold. Interest in the new district is unabated. Snow has interfered with operations. Ten mining companies have been incorporated.

The Utah, Nevada & Idaho Telephone Co. is arranging to construct a branch line from Oreana to Rochester canyon. The shaft at the Big Four is down 12 ft., of which 8 ft. is ore assaying up to $131 per ton. Over 1200 sacks of ore is ready for shipment. Work has begun on the adit of the Rochester Mines Co., and will be driven 750 ft., giving a depth of 430 ft. The Lincoln Hill Gold Mining Co. has been incorporated with a capital of $1,500,000. Water for the new field is procured from springs two miles distant, and is selling at $1 per barrel. A new road is to be constructed to Lovelock. A number of well known mining men have visited the district. Two lawsuits in connection with certain claims have already been started. At the Weaver group of claims, in which George Wingfield is interested, three adits are being driven to prospect the country.

LYON COUNTY

All the mills and cyanide plants at Silver City have been closed, owing to the cold weather, and will remain shut down until spring.

NYE COUNTY

The mines at Tonopah treated 10,247 tons of ore, worth $215,280, during the week ended January 18. In December the Belmont mill treated 11,740 tons, yielding 318,730 oz. of bullion, the net profit being $172,450; Tonopah, 14,464

PART OF WESTERN NEVADA.

tons, yielding $229,250 from 235,960 oz. of bullion and 81 tons of concentrate, profit being $121,400; and the West End, 4350 tons, yielding a profit of $8.50 per ton, with 93.50% extraction.

The quarterly report of the Tonopah-Belmont Development Co. gives the following particulars:

Bullion production	$1,177,972
Expenditure	653,889
Net earnings	$ 524,083
Available resources November 30, 1912:	
Due from smelters	$ 337,262
Due from others	4,408
Loans on collateral	250,000
Cash in banks	471,617
Total	$ 1,063,287

On the 350-ft. level of the Earl mine, 12 ft. of ore worth $20 per ton has been opened in the east drift at 120 ft. from the shaft, and 6 ft. of $35 ore was cut in a raise being driven 70 ft. from the shaft. Sinking is to be resumed at the White Caps mine from 235 to 300 ft. At the Manhattan Mustang, lessees have cut, in the main shaft, a 15-in. vein in which is a streak of leaf gold about ½ in. thick. Specimens from this are of rare beauty and the best seen in the district.

WHITE PINE COUNTY

Notwithstanding the cold weather of late, the Giroux company is producing over 1000 tons of ore per day. There have been no new developments recently.

A report of S. H. Williams, general manager for the Smokey Development Co. at Ely, states that work was started on June 18, 1912, to cut the ore found in No. 3 drill-hole, to cross-cut the porphyry area a width of 1350 ft., and to open at depth the contact of porphyry and limestone. No. 3 drill-hole was reached on October 7, but water has interfered with sinking for the copper ore. The adit is in 475 ft., and at 290 ft. sulphide ore was cut. From 290 to 319 ft. the ore is hard and forms the usual casing for porphyry. From 351 to 392 ft. ore averaged from 0.6 to 2.7% of copper. The dump contains 1100 tons of ore assaying 1.5% copper, and 60c. in gold and silver.

NEW MEXICO

GRANT COUNTY

During December the Chino mill treated approximately 5000 tons of ore per day, and the production of copper was 3,545,100 lb., a decrease of 500,000 lb. in November.

SOCORRO COUNTY

The Ernestine mine is the largest gold-producer in this state, and has paid dividends for several years. E. A. Wayne recently returned to Mogollon from New York, where a new company was formed to take over the Ernestine and Maud mining companies. The Maud mine will be further developed and the mill of the Ernestine enlarged. Mr. Wayne will be general manager for the new company, with headquarters at Mogollon.

OREGON

BAKER COUNTY

The Black Butte mine, near Fox valley, has suspended operations for a while. Considerable work was done during the past six months. The financial condition of the company is unsatisfactory, and $6000 is necessary to cover outstanding debts. A roller mill and four stamps are ready for erection. Three shifts of five men each are employed at the sampler of the Oregon-Idaho Investment Co. The Powder River Dev. Co. dredge, at Sumpter, was floated and commenced work on January 7. It has a capacity of 8000 cu. yd. per day, power being supplied by the Eastern Oregon Light & Power Company.

UTAH

SALT LAKE COUNTY

At Alta, the three-story boarding-house of 200-men capacity, of the Columbus Consolidated and Columbus Extension Mining companies, was destroyed by fire. The loss was $25,000, and insurance covers $10,000.

SUMMIT COUNTY

During the week ended January 11, shipments of ore from Park City were 1520 tons; and during the past year, 92,648 tons of ore and concentrate, of which the Silver King Coalition contributed 32,726, Daly West 27,481, Daly-Judge 24,316, Grasselli Chemical Co. 3694, and Ontario 1518 tons.

WEBER COUNTY

Ogden has two companies which manufacture cement. The mills employ 350 men with a monthly payroll of $15,000, and during 1912 produced about 775,000 bbl., of which 600,000 was produced by the Union Portland Cement Co. and 175,000 by the Ogden Portland Cement Company.

WASHINGTON

FERRY COUNTY

A movement is on foot to form a large company to control the principal mines of the Republic district, erect a

large concentrating plant, and supply mines and mills with electric power. The Washington Water Power Co. is said to be behind the scheme, and also it is reported that the West Kootenai Power & Light Co. wishes to compete for power-supply, as it is already erecting a transmission-line from Grand Forks to Republic.

Over 1300 shareholders in the Washington Water Power Co. have received a dividend of 2% on January 2, which totaled $280,000, making a total of $1,120,000 paid in 1912. The outstanding stock of the company is $14,067,900. The International Power & Manufacturing Co. was planning to build a series of power-plants in the Pend d'Oreille river, situated partly in the Kanishu National Forest and partly in a power-site reserve, which would produce 200,000 hp., and the United States Government has held up extensive land patents of the company on the ground that the company was trying to "free itself from all control by the Government by securing patents to lands under the guise of mining claims, or by railroad scrip filings, in combination with a special dam license." The Secretary of the Interior refers to the case as "an example of the methods used to defeat Federal ownership."

CANADA

British Columbia

The British Columbia Copper Co. paid a dividend amounting to $88,756 on January 15, making $355,024 for the past year, and $704,155 to date. A conference between the directors and superintendents and E. F. Voigt has been held in New York in connection with the Voigt mines, which the company has been operating under an option for several months. On December 31 the Hedley Gold Mining Co. paid the usual dividend of 3%, and an extra one of 12%, making $360,000 for the year.

The Consolidated Mining & Smelting Co. has acquired a three-quarter interest in the Silver King, Dandy, and Ollie claims, situated on Toad mountain, four miles south of Nelson. The first-named property has produced ore worth over $5,000,000. Diamond-drilling has shown ore to a depth of 1130 ft., carrying 0.02 oz. of gold, 8.3 oz. of silver, and 2% of copper. The mine is ready for ore production and is supplied with electric power. The Dandy vein is an extension of the Silver King and averages 4½ ft. in width. It has been opened by open-cuts and adits, and ore will be sent to the Trail smelter.

Ontario

Kerr lake is about 50 ft. deep and covers an area of 40 acres. The various companies owning land under the lake, namely, the Crown Reserve, Kerr Lake, and Drummond, which own 23, 11, and 6 acres, respectively, have come to an agreement, and have applied to the Mining Commissioner for permission to pump out the lake. Pumps will be put on a raft on the lake and the water will eventually flow into the Montreal river. The Carson vein of the Crown Reserve mine has produced 8,253,279 oz. of silver, and by draining the lake about 2,781,000 oz. will be recovered, and the Drummond company will be able to prospect its ground better. The case will be heard early in February. The lake had to be lowered 8 ft. before the Crown Reserve could begin operations.

On January 14, 121 bars of silver bullion were shipped from Cobalt, most of which is for England. The shipments were as follows:

Mine.	Ounces.	Value.
Buffalo	54,712	$35,000
Nipissing	63,641	39,777
Townsite	2,770	1,750
Casey-Cobalt	2,394	1,520
Total	123,517	$78,056

During the year ended October 31, 1912, the Coniagas Mines, Ltd., produced 3,508,377 oz. of silver from 53,627 tons of ore, at a cost of 8.51c. per ounce, the average price received being 59.39c. Dividends amounted to $1,448,000, making a total to date of $4,280,000. Development of new orebodies has exceeded shipments by 1,400,000 oz., the reserves now being estimated at 13,953,000 oz. of silver.

Without an explosion occurring, the entire plant of the Dinitrolite Explosives Co. was destroyed by fire in the last week of December 1912. The fire was caused by an incandescent globe exploding above the cartridge filler and igniting the powder. The loss will be over $10,000.

P. A. Robbins, general manager for the Hollinger Gold Mines Co., states that during the five months that the mine was working last year, the revenue amounted to $860,000. The profit from October 27 to November 30 was $94,613. During the strike the mill averaged 226 tons of ore per day. On January 28 another 3% dividend will be paid, making $36,000 to date.

MEXICO

Chihuahua

The annual report of the Batopilas Mining Co. for 1911 states that during the year 515,824 oz. of silver was shipped, realizing an average of 54.29c. per ounce. Accounts show a deficit of $17,409, while that for 1910 was $106,258. Assets are stated as $137,059, and liabilities $97,037. The first six months of 1912 gave a profit of $25,000.

The mining town of Cusihuiriachic was shaken by an earth tremor recently. At Parral, the mill of the Alvarado Mining & Milling Co. has been increased to 400-tons capacity. The company is working the Presena, Las Cruces, and

PALMILLA CYANIDE PLANT, PARRAL DISTRICT.

Palmilla mines. J. I. Long is general manager. The San Patricio mine at Naica has resumed work after several months' idleness, also the Ramon Corona. At both mines a total of 80 men are employed.

It is reported that the Venture Corporation, of London, has secured control of the Naica company's property in the Naica district, for $6,000,000. The Venture company has had an option for some time on this mine, which is one of the richest in the district.

Jalisco

The volcano of Colima broke into violent eruption on January 20. Little lava has been ejected from the crater, which, however, emitted vast quantities of smoke and sand, while deadly gases formed an unusual feature of the eruption. The last eruption occurred in 1903, and recently the people of the city of Guadalajara were warned that there was likely to be trouble. Inhabitants are fleeing from the vicinity, and railroads have been covered several feet with sand.

Sonora

The Moctezuma-Arizpe Mining Co. has sent to its property, 18 miles northeast of Cananea, four Wilfley tables and four Callow tanks, which will bring the capacity of the mill up to 100 tons per day. The company is also shipping ore to smelters regularly. The Arizona-Sonora Mines Co. is to erect a 50-stamp mill on its Juan Cabral property, near Magdalena. La Flora company, operating the Nopalera mine, near the San Miguel river, will also erect a mill.

Zacatecas

The Mezquital Mining Co., which has taken over the Mezquital de Oro properties in this state, is to start milling operations, the 50-stamp mill and cyanide plant having been overhauled and improved. About 200 tons per day will be treated for a while. M. F. Slattery is in charge of the properties.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

RALPH ARNOLD is here.

ROBERT MCSHANE is visiting Arkansas.

SUMNER S. SMITH is in San Francisco.

JUAN FELIX BRANDES is in San Francisco.

N. B. KNOX is returning to London from Peru.

R. T. SILL is in Sonora, Mexico, upon professional work.

C. R. CORNING is expected back from France during the week.

ALBERT BURCH has returned from spending the holidays in Berlin.

C. F. RAND has gone to Cuba but will return early in February.

F. LYNWOOD GARRISON will leave for Colombia the first of February.

J. W. MATHER has gone to New York and from there will go to Ecuador.

D'ARCY WEATHERBE was expected in London from Peru early in January.

JOHN P. CHADWICK is now with the Braden Copper Co., at Rancagua, Chile.

JAMES S. WRATH is now with the Chile Exploration Co. at Autafogasta, Chile.

ALF WELHAVEN is returning to San Francisco by way of London and New York.

BERTRAM HUNT is metallurgist at the Broomassie mine, Tarkwa, Gold Coast Colony.

J. A. L. HENDERSON has returned to London from Canada, expecting to remain about three months.

F. H. PROBERT is engaged upon professional work in the Montezuma district of Sonora, and will visit Arizona before returning to Los Angeles at the end of this month.

GEORGE E. FARISH is representing the John McMartin and allied interests in British Columbia, and is also general manager of the Mother Lode mine at Sheep Creek. He will make his headquarters at Nelson, B. C.

FREDERICK BURRIDGE, formerly manager of the Bunker Hill & Sullivan mine and later superintendent and manager for the Federal Mining Co., has been elected president of the Nipsic Mining Co. and will take charge of operations.

The following committees of the CALIFORNIA MINERS' ASSOCIATION have been appointed by the president, W. C. RALSTON. Committee on Legislation, E. C. VOORHIES, chairman, H. FOSTER BAIN, WAKEFIELD BAKER, C. M. BELSHAW, E. B. BRADEN, F. W. BRADLEY, NEWTON CLEAVELAND, C. H. DUNTON, E. C. HUTCHINSON, H. T. POWER, J. R. TYRRELL, F. R. WEHE. Executive Committee, B. M. NEWCOMB, chairman, E. H. BENJAMIN, C. M. BELSHAW, S. B. CHRISTY, NEWTON CLEAVELAND, LOUIS ROSENFELD, E. C. VOORHEIS. Committee on California Debris Commission, W. W. WAGGONER, Chairman, R. L. DUNN, W. F. ENGLERRIGHT, H. T. POWER, A. A. TREDGIDOE.

Obituary

GEORGE AUGUSTUS KOENIG died in Phialdelphia recently, at the age of 68. Born at Willstaett, Germany, in 1844, he was educated at Karlsruhe, Berlin, Heidelberg, and Freiberg, and came to this country in 1869, as chemist for the Tacony Chemical Works. Later he became a member of the staff of the chemical department of the University of Pennsylvania, and in 1874 began the development of a department of mining and metallurgy, much as Thomas Egleston at Columbia, and G. J. Brush at Yale had earlier done. In 1892 he became professor of chemistry at the Michigan College of Mines, being the senior member of that institution at the time of his death.

World's Production and Consumption of Copper, and Lead

L. Vogelstein & Co. present the following preliminary estimate of the world's production and consumption of copper in 1912 and comparisons with previous years.

PRODUCTION (TONS OF 2240 LB. EACH)

	1912.*	1911.	1910.	1909.
Germany	32,000	30,500	28,800	23,500
Austria-Hungary	3,000	2,539	2,250	1,750
Italy	3,000	3,000	3,000	3,200
Russia	29,000	25,500	22,300	18,450
Sweden and Norway	10,000	9,500	7,000	12,500
Spain and Potugal	58,000	55,000	53,000	53,000
United States	558,000	487,300	482,200	487,020
Mexico	72,000	54,050	58,800	56,250
Canada	33,000	24,000	22,500	21,420

United States	365,000	316,791	334,565	314,755
	1,045,000	983,300	930,290	826,239

*Estimated.

Consumption of copper includes old metal in all countries except the United States, and the figures have only a relative value.

Stocks of copper in England, France, Hamburg, and Rotterdam, as per foreign statistics, were:

	Tons.	Decrease, tons.
December 31, 1910	94,800	.....
December 31, 1911	60,750	34,050
December 31, 1912	35,041	25,702

Price fluctuations have been as follows:

	Standard spot (London), £	s.	d.	Electrolytic (New York), cents.
Opening	63	8	9	14.05
Highest	79	15	0	17.5875
Lowest	60	16	3	13.80
Closing	76	12	6	17.45
Average	72	18	9	16.341
Average, 1911	57	1	1	12,376

The following table of lead production and consumption is compiled from figures of the U. S. Geological Survey.

Production from domestic ore:	1912.	1911.	1910.	1909.
Desilverized	229,765	201,223	192,583	194,033
Soft lead	169,551	191,619	169,244	151,222
Total	399,316	392,842	361,827	345,255
Production from foreign and base bullion	81,649	94,134	108,553	102,857
Total U. S. smelter prod.	480,965	486,976	470,380	448,112
Consumption (est.)	401,088	399,472	376,021	370,013

In submitting these figures, however, L. Vogelstein & Co. call attention to the fact that so far as consumption is concerned, no importance should be attached to the estimate of 401,088 tons, an increase of but ¼ of 1% over 1911. An examination of the pig iron, copper, spelter, and tin figures shows that the consumption of pig iron increased 26%; copper, 16%; spelter, 21%, and tin, 12%, or an average increase of 19%. It is probable that the consumption of lead increased at least 15%, and amounted to fully 460,000 tons. The production from domestic sources being approximately 400,00 tons, the difference has been drawn from stocks, and the quantity on hand is now the smallest since 1906-7. There are the best of reasons for stating that stocks at the present time constitute no more than a working balance with the exception of small quantities held in Missouri. Motives of enlightened self-interest as well as sound public policy should dictate to the lead smelters the wisdom of again reporting stocks.

Company Reports

MT. LYELL MINING & RAILWAY CO., LTD.

This well known company has had an unfortunate time of late with a fire, and a fall of rock which killed over 40 men. The half-yearly report, submitted to the shareholders on December 13, 1912, states that the output of ore from the Mt. Lyell and North Mt. Lyell mines amounted to 155,160 tons, of which the former produced 74,724 tons from underground, and 21,523 tons from the open-cut. The ore reserves in this property total 2,361,182 tons, containing 0.532% copper, 1.96 oz. of silver, and 0.027 oz. of gold per ton. Very little development was required during the period under review. The North mine produced 58,913 tons. The principal development undertaken consisted of diamond-drilling. At the 850 and 1000-ft. levels, bore-holes have proved the continuation of the North Lyell orebodies into the recently purchased Comstock property. A vertical bore from the 1100-ft. level proved the downward continuation of the orebody. Ore reserves are estimated at 1,083,752 tons, carrying 6% of copper, 1.33 oz. of silver, and 0.005 oz. of gold per ton. From the Chester mine 6748 tons of pyrite was extracted for acid-making at the Yarraville, Victoria, and Port Adelaide, South Australia, chemical works. The Mt. Lyell Comstock Copper Co.'s property has been purchased outright at a cost of $90,000. The North mine's orebodies dip toward the Comstock leases, and it is thought that another lode may become of considerable value to the parent company. Development in all the mines covered 1455 ft., including 707 ft. of drilling. At the smelting plant an average of 2½ blast-furnaces were continuously in operation, and treated 157,296 tons of dry ore averaging 1.62% copper, 0.27 oz. of silver, and a trace of gold per ton producing 3124 tons of copper, 213,285 oz. of silver, and 4316 oz. of gold. The cost of producing blister copper was $4.80 per ton. Since August 1903, 3,458,645 tons of ore and fluxes have been smelted, yielding 72,275 tons of copper, 5,991,072 oz. of silver, and 154,538 oz. of gold; while, with the former Mt. Lyell company, the total is swelled to 120,852 tons of copper, 10,112,473 oz. of silver, and 310,290 oz. of gold. Good progress is being made with the preliminary work in connection with the Lake Margaret hydro-electric power scheme. The chemical and superphosphate works at Yarraville, Port Adelaide, and Fremantle maintained a full output of high-grade fertilizers. At Mt. Lyell the rainfall on 118 days was 61 inches. During the half-year 2128 tons of copper was sold, at an average price of £81 2s. 11d. per ton. Total revenue from blister copper, chemical products, and the railroad was $1,620,000, and net profits, after writing off development and depreciation, were $520,000, out of which $360,000 was paid in dividends, making a total of $8,496,000 from this company, and $13,278,800 including the old Mt. Lyell company. Assets total $3,300,000, including $960,000 in blister copper and $1,000,000 in stocks, while liabilities total $570,000. This interesting report is accompanied by a plan of the North Lyell mine.

Book Reviews

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

HAZELL'S ANNUAL FOR 1913. By Hammond Hall. 592 pp., index. Hazell, Watson & Viney, London, 1913. For sale by the *Mining and Scientific Press*. Price $1.50.

Hazell's is one of the best of European annuals, and it is to be regretted that no similar volume covers the American field. Though it appears before the end of the year, it covers the whole field up to the end of November, and to American readers is of especial service in presenting in concise form an impartial review of European progress for the year, as well as serving as a general reference volume.

EXPLOSIVES. By H. Brunswig. Translated and annotated by L. E. Monroe and A. L. Kibler. 350 pp., ill. John Wiley & Sons, New York, 1912. For sale by the *Mining and Scientific Press*. Price $3 net.

This is an admirably condensed, non-mathematical, critical résumé of present knowledge of the theory of explosives, and is unusual in that the author not only states that all the material has been compiled from easily available literature, but intimates that considerations of private employment have induced him to refrain from critical remarks where a contradiction exists between the literature and his own knowledge of the facts. Books in which there is little that is new are common, but one in which the author maintains there is nothing original is decidedly unusual. Possibly this is why he has been able to expound, summarize, and condense with unusual skill. The advance of physical chemistry has been so rapid that few have been able to keep conversant with the fundamental changes it has made in the concepts of technology. All those who have to do with the use or manufacture of explosives will be correspondingly grateful to Dr. Brunswig for gathering together the facts in regard to explosives and arranging them in accord with modern physical chemical views in so lucid a manner. The translator likewise deserves gratitude for rendering it into the vernacular, for it is but seldom that the work of a master of an art is translated by another of equal rank.

REFRACTORIES AND FURNACES. By F. T. Havard. 335 pp., ill. The McGraw-Hill Book Co., New York, 1912. For sale by the *Mining and Scientific Press*. Price $4 net.

This is the day of treatise upon special topics, and the library of a well read engineer grows rapidly, since he must now purchase, and read if he finds time, numerous treatises on all the allied phases of his field of work, instead of relying upon a few general books covering the whole field. This volume complements and supplements Damour's 'Industrial Furnaces,' translated by A. L. Queneau a few years ago, as it deals with practice, while Damour's treatise is chiefly theoretical. Mr. Havard is now associate professor of metallurgy at the University of Wisconsin, after having won his spurs in the practice of the metallurgical profession, and writes, therefore, from a comprehensive knowledge of the art. He has gone into the subject with commendable thoroughness, from the preparation of refractory materials to the construction of furnaces and the testing of refractories. The appearance of the book is somewhat marred by the use of threadbare illustrations, and the diagram of a long-hand roaster, on p. 167, is in a fair way to become as much a classic as the engravings from Agricola, without which the historical chapter of any recent book on mining topics would be as bare as a front parlor without Countess Potocka and Baby Stuart upon its walls. Nearly every engineer and all metallurgists have to deal with refractory materials, in one way or another, and will find much of interest and value in this book.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

VENTILATION at the Robinson Deep mine has been improved by installing a fan on the 1900-ft. level. It is of the Sirocco type, 84-in. diam. and has a capacity of 178,400 cu. ft. of air per minute, at 4000 ft. above sea-level.

NEITHER an extremely dictatorial nor a lax management results in efficient operation in any mine, and harmonious relations between heads of departments are impossible under either of these two conditions.

PRICES of merchandise from foreign countries, imported into the United States, show a continued advance, and in October 1912, out of 75 articles listed, 45 showed higher prices than in the corresponding month of 1911.

TO CALCULATE water-power quickly: $\frac{\text{sec-ft.} \times \text{fall in feet}}{11}$ = net horse-power on water-wheel realizing 80% of theoretical power.

FEED-WATER HEATERS and economizers serve the same purpose, but it is not desirable to install both. A saving of over 10% of coal has been shown by using the latter; but when the draught is already poor, the economizer is inadmissible.

DIAMOND-DRILL RECORDS have shown that time efficiency in drilling varies from 60 to 76%. If too great a pressure is applied to the 'bit' in the effort to accomplish faster work, the probability of deflection in the hole and consumption of carbons are much increased.

STAMP duty at the Nickel Plate mill, British Columbia, was increased during 1912 by the use of warmed water, instead of icy-cold water from the penstock; a magnet was fixed over conveyors to pick out pieces of steel from the ore; and the use of coarser screens.

BUCKET ELEVATORS, for lifting 350 tons of crushed ore per day from a jaw-crusher to the mill-bin, of the Yuanmi mine, in Western Australia, is 18 in. wide, of 8-ply canvas, rubber-faced. The buckets are 16 in. wide, spaced 12 in. centres, and the speed of the belt is 190 ft. per minute.

AUXILIARIES in a power-plant generating 500 kw. absorbed 12.9% of the power, as follows: accumulator pump, 1.25%; dry-air pump, 1.75%; boiler-feed pump, 3.4%; and circulating pump, 6.5%; while in a 5000-kw. turbine plant they absorbed from 3.4 to 2.1% of the power, according to load.

IRON-ORE SUPPLY of southern Sweden has been estimated at 157,553,000 tons, divided into three groups according to the amount of phosphorus present. The total amount of iron ore mined in all Sweden from 1301 to 1910 is estimated at 122,554,593 tons, and pig iron production 37,871,623 tons.

MERCURY may be purified by streaming small quantities through $HNO_3 + HgNO_3$. Larger quantities may be treated by passing air through, and afterward shaking up with powdered charcoal, which has been allowed to absorb oxygen. The charcoal will rise to the surface, carrying a scum of oxid s with it.

PUMPS used for filling clean-up presses should be run direct by a small variable-speed engine, preferably driven by compressed air. A fairly heavy fly-wheel is essential on the crank-shaft of the pump, so that the slowest speed may be maintained for 'hardening-up' without an unnecessarily high pressure resulting.

SAMPLING ground may be done after a little practice with any good air-hammer, weighing about 10 lb. A rose bit may be used, the rock cut away varying in size from lumps to dust. The hammer strikes from 1500 to 2000 blows per minute, is easily regulated by a trigger, and by holding the drill well up against the face, chips do not fly as when a hammer and moil are used. In ten minutes a clean cut 2 in. wide, ½ in. deep, and 2 in. long can be made.

PRELIMINARY load of balls in a ball-mill, as regards size, is often arranged to correspond, as nearly as possible, with the normal load under working conditions. This corresponds to about 45% by weight of large balls, each about 18 lb.; 20% of medium sized balls, each about 9 lb.; and 35% of small balls, each about 5 lb. Tests at several Kalgoorlie mills have proved that this is not absolutely necessary, there being little difference in starting a mill this way or with large balls. It has been suggested that the preliminary load of a tube-mill should be similarly arranged. In any case the fracture and abrasion of the poorer portions of the load would soon supply the mill with the normal quantity of smaller pebbles.

COPPER smelting in the electric furnace has been tried by the manager of the Ugine smelting works. He used as reducing agents charcoal, coke, and anthracite, all of which proved suitable; limestone served as flux. The electrodes consisted of carbon and soft steel poles and water-cooled copper poles were employed. The ores contained from 10 to 20% oxide of copper, 30% SiO_2, 10% Al_2O_3, from 3 to 5% oxide of cobalt, and from 7 to 32% moisture. The product obtained was never anything better than black copper, spoiled by the presence of considerable quantities of cobalt, iron, and silicon. From 1000 to 1200 kw. current and 8 kg. of electrodes were consumed per ton of ore, and the consumption of the reducing agents averaged 25% of the copper content of the charge. As a result of these experiments, it may be concluded that for producing copper the electric furnace is not by any means an unqualified success.

LITTLE information in regard to the extraction of lithium from its ores in the United States is available. Numerous electrolytic methods are known. A process has also been proposed by Hugo Muller and is outlined in Roscoe and Schorlemmer's 'Treatise of Chemistry.' It consists of dissolving the mineral acid with a ferric salt. The solution is evaporated and the chloride of lithium removed by dissolving in water. Manganese can be removed from the solution by treatment with barium sulphide and the excess of barium removed with sulphuric acid. The lithium is finally evaporated with oxalic acid and ignited to convert to the carbonate. Another method employed in a Paris refinery is by using acid sodium sulphate, pulverising the acid sulphate and the ore, then mixing them in exactly determined proportions, gradually heating this mixture to redness, lixiviating the roasted mass to obtain a solution of lithium sulphate, and after purification, precipitating the lithium as the carbonate (Li_2CO_3) by the addition of sodium carbonate.

GOLD LEAF industry of Russia is centred at Moscow, where there are five large establishments and a number of smaller ones producing about $500,000 per annum. There are employed 600 men, 300 boys, and 100 women, whose wages range from $20 to $25, $5 to $10, and $8 to $10 per month respectively. In the United States there are over 80 establishments producing gold and silver leaf and foil, employing over 1500 persons who average $460 per year in wages. In Russia the gold and apparatus comes from Germany, while molds and skins for the United States come from England, the output of the United States factories being worth about $2,630,000. Gold-beater's skin is a delicate membrane prepared from the large intestine of the ox, and may be beaten continuously for several months with a 12-lb. hammer without much injury. Gold is first cast into oblong ingots ¾ in. wide, weighing 2 oz., and then rolled into a ribbon 1/800 in. thick, cut into pieces 1 in. square, placed between leaves of vellum and beaten with a 16-lb. hammer until the final leaf is 1/200,000 in. thick. Nearly all the product is made by hand.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

GRANT OF MINERAL RIGHTS—USE OF SURFACE

The grantee of coal under land, with general mining rights and the free right to use the surface so far as necessary for mining, may dump the waste or refuse of the mine at its entrance, and use as much of the surface for that purpose as is strictly necessary and reasonable, without liability to the grantor in damages for such use.

Dewey *v.* Great Lakes Coal Co., (Pennsylvania) 84 Atlantic 913. May 13, 1912.

RESUMPTION OF ASSESSMENT WORK PREVENTS FORFEITURE

Two locators, having failed to do their assessment work for two years on certain mining claims, at the beginning of the third year made an attempted re-location of the same claims, adopting the same corners, boundaries, and discovery work, and thereafter proceeded with diligence and large expenditures of money to develop the property. Subsequent to the attempted re-location and while the re-locators were at work, third parties attempted to locate the ground, claiming that the original locations were forfeited for non-performance of assessment work and that the attempted re-location was void because the requirements of Arizona law as to discovery work on re-located claims had not been complied with. It was held that regardless of the invalidity of the re-location, assessment work had been resumed under the original locations before the rights of third parties had attached and that hence no forfeiture under these locations had taken place.

Peachy *v.* Gaddis (Arizona), 127 Pacific, 739. September 28, 1912.

LIEN DOES NOT ATTACH TO OIL WELL PRODUCT

Under Kansas and Oklahoma statutes giving laborers liens upon oil wells and appliances, buildings, and appurtenances for operating them, and upon the leasehold right thereto, no lien attaches to the product of the well, after it has been separated therefrom.

Black *v.* Giarth (Kansas), 128 Pacific, 183. December 7, 1912.

OIL LOCATIONS MADE PRIOR TO MARCH 2, 1911

The Secretary of the Interior has instructed the registers and receivers that the chiefs of field division should make such field examinations as are advisable and necessary, particularly of lands embraced in a withdrawal, with a view to determining the time when development work was begun and the extent and character thereof and the continuousness and diligence exhibited in prosecuting the same. The Act of March 2, 1911, being retrospective only in its operation, upon receiving an application for patent of lands located prior to its passage, the local officers should communicate at once with the proper chief of field division with a view to ascertaining the foregoing facts. Reports of the results of the examination made by the chief of field division will be submitted to the Commissioner of the General Land Office, upon receipt of which the local officers will be advised as to the action to be taken.

Instructions, approved July 11, 1912. 41 Land Decisions, 91.

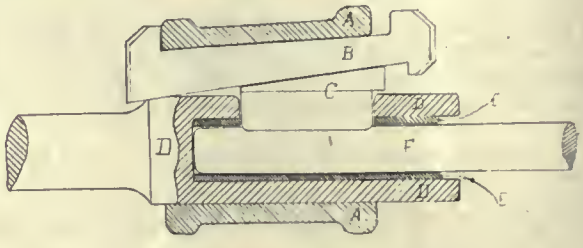
INSUFFICIENT DISCOVERY

Country rock in which it is claimed 'kidneys' of copper ore may be expected to be found, is not itself a lode within the meaning of the mining laws, and the exposure of such rock within the limits of a lode claim, which may or may not contain mineral, does not constitute the discovery of a vein or lode within the meaning of the law and is not a sufficient basis to support a lode location.

Rough Rider and other lode claims (on rehearing before Secretary of Interior), 41 Land Decisions, 255. September 5, 1912.

Schorlemmer Drill Chuck

A new chuck to hold drill steel in the reciprocating type of rock-drilling machines, has been invented by a Canadian, H. W. Schorlemmer of Rossland, B. C., and is now about to be made available to the users of rock-drilling machines in the United States. This chuck can be fitted on any of the reciprocating type of rock-drilling machines by turning down the end of the piston rod, so as to make a shank about 7 in. long and 2¼ to 2⅞ in. diameter, according to the size of the machine. This shank must be slotted, longitudinally, like the slot in a bushing, to take a key which ohlds the drill. Tht same standard bushings are used with this as with the U-bolt chuck.



A, COLLAR; *B*, WEDGE KEY; *C*, DRILL KEY; *D*, PISTON; *E*, BUSHING; *F*, DRILL-SHANK

The collar, *A*, is adapted to slide freely on the turned end of the piston rod *D*, and has an extension on one side which holds the wedging key *B*; this key also slides freely in the collar. The drill shank *F*, being inserted in the socket or bushing *E*, the drill-key *C* loosely engaging it, the collar and wedging-key, as the drill bit strikes the ground in the first blow, will be carried forward by their own momentum and the inclined surfaces of the two keys will cause the inner or drill-key *C* to move inwardly with considerable force, thereby crowding the drill shank *F* against the opposite wall of the bushing and gripping it with great firmness. Subsequent blows of the drill bit serve only to make the engagement still tighter. The construction and arrangement of the collar so as to slide forward with the wedging-key, in the tightening operation, is an important feature, as the momentum of the heavy collar, added to that of the wedging-key, is sufficient to insure the drill-key being driven against the drill-shank with such force as to prevent any possible loosening of the drill in the operation of the machine, and to prevent the drill from being pulled out of the bushing in case it should stick in the hole.

To release a drill from this chuck, the forward end of the wedge-key *B* is struck with a hammer, driving the key backward and thereby loosening the drill-key, which allows the drill shank to be removed from the bushing with ease. Owing to the arrangement of the keys this operation is very simple, requiring not more than one or two blows with the hammer to release it.

The collar and keys are easily removed from the piston-rod, when the drill shank is not in the bushing, by allowing the drill-key to drop down in its slot as far as permitted by the shoulders on it; then hold the wedge-key up against the top of the collar. With the parts in this position the collar and the wedge-key can be slid backward past the drill-key, the lower gib on the wedge-key can be lifted out of its slot and the collar and wedge-key be drawn forward over the end of the piston-rod. It is practically impossible for the operation of taking the chuck apart to be done accidentally, as the large key will always follow the movements of the small key, thus preventing any displacement of the collar or keys.

This chuck has been tested in the mines at Rossland, B. C., for three years, and has proved practical, it is also claimed to be more economical of operation than the U-bolt chuck, besides cutting down the cost of drilling, owing to the time saved in changing drills. The Consolidated Mining & Smelting Co., of Canada, Ltd., is using it exclusively on all drilling machines. The Le Roi, Le Roi No. 2, Josie, and other mines in the Rossland district have been using it with success for the past year and a half.

TABLE OF CONTENTS

EDITORIAL

DISMISSAL of Mr. Whitman Symmes by the Comstock Pumping Association suggests that any engineer doing good work on the Comstock is bound to get into hot water.

FORECLOSURE proceedings have been directed by the United States District Court, under a trust deed and mortgage held by the Continental & Commercial Trust & Savings Bank of Chicago, and thus the properties of the Penn-Wyoming Copper Company pass to new owners. This ends a long fight and clears the way for sale of the properties.

A HOLDING company, it is announced, is to be formed to take over and operate the properties of the St. Joseph Lead Company, the Doe Run Lead Company, the Mississippi River & Bonne Terre Railroad Company, and affiliated concerns. With resulting economies these excellent properties may be expected to improve even upon their present good records.

WALL STREET is disturbed not only by the 'money trust' investigation and the "antagonistic" attitude of the Governor of New York, but most seriously of all by the continual loss of patronage. Recent inquiry developed the fact that traffic handled by elevators in representative office buildings in the New York financial district is now about one-third the normal. One of the humors of the present situation is the hailing of the election of Mr. Bernard M. Baruch to a position on the Law Committee as an evidence of reform from within.

FIXED ideas are hard to change. The Alaska Treadwell mine became famous for its low costs while working an open pit. For some years all mining on Douglas island has been done underground, and most of the ore now stamped comes from about 1600 feet in depth. Nevertheless, so well informed a periodical as the *South African Mining Journal*, placing the Alaska Treadwell at the head of the list of great mines with low working costs, says it "scarcely can be fairly contrasted with other mines where quarrying or open-cast working is not practicable." In fact the low costs are due to the large size of the orebody, its simple character, and the excellent management the mine has always enjoyed.

DURING the past few weeks a decided public interest has been manifested in Cobalt, and as a consequence the majority of the stocks have been ruling at higher prices. The appreciation of value is entirely legitimate and is induced by the high price of silver and the favorable developments on

the various properties. This interest has been particularly noticeable in England, where several flotations have recently been made. Following the striking success of the English-held Townsite and Casey Cobalt mines, a leasing company was formed to work the old Silver Queen mine. The shares of this company are selling at a premium of over 100 per cent on the London market, although the venture is a rather doubtful one. A few weeks ago, Sir Henry Pellatt negotiated a deal for the purchase of the Cobalt Lake mine, and the stock is now being sent in for transfer. The latest venture for English capital in Cobalt is the purchase of control of the Chambers-Ferland. No public announcement has as yet been made, but the money is ready, and it seems assured that the deal will go through. Several other Cobalt mines are being prepared for introduction on the London market, and in this connection it would be well to exercise caution. If the shares of the companies already floated are in receipt of public favor, there is no doubt but that every effort will be made to float all sorts of undesirable properties. All new companies should be subjected to the fullest investigation, and every effort should be made to stamp out 'wild-cat' flotation, which, in a district as well known as Cobalt, would have a markedly harmful effect upon the mining industry of Canada.

Smelter Fume Control

Experimental work with the Thiogen process for the reduction of SO_2 of smelter fume to elemental sulphur by the actions of hydrocarbons, aided by the use of a catalyser, was described in some detail in our issue of April 6 last. As outlined at that time it was found in practice that reduction of the SO_2 by this means was feasible, but, as is usual in the development of new methods, it was necessary to overcome a number of mechanical difficulties in order to adapt the methods to the requirements of the conduct of smelting operations. Chief among these are the freeing of the gases from dust, which would contaminate the sulphur, decreasing of the free oxygen content of the gas as much as is consistent with the successful conduct of roasting operations, obtaining of uncontaminated sulphur, and the collection of the reduced product. During the past year these problems have been the subject of study by capable mechanical and chemical engineers, and while no formal announcement has been made, encouraging progress has resulted. The roasters employed are of the usual multiple hearth type and by means of a by-pass and fan a portion of the escaping gases is returned to the lowest hearth, thus raising the sulphur content of the portion escaping to the reduction chamber to 8 or 9 per cent of SO_2. This gas, from which the dust has been allowed to settle, is mixed with producer gas made from crude oil, at a temperature of 700 to 800°C., and is passed through masses of the catalytic material, earlier described. This reduction was formerly accomplished by the use of a spray of crude petroleum, with the result that the sulphur produced was mixed with petroleum. Experiments were accordingly made with gas made from oil, also with unsatisfactory results, as the gas still contained appreciable quantities of liquid and tarry products. Experiments are now in progress with a type of producer, made by the Western Gas Engine Company, in which the producer gas is drawn through a bed of glowing coke before escaping from the producer, with reported excellent results. The sulphur thus reduced is allowed to escape into a cooling chamber, where it is cooled by a water spray to below the temperature of ignition. The problem of the collection of the resulting mixture of flowers of sulphur, milk of sulphur, and liquid material has not as yet received extensive study.

In our issue of January 4, Mr. S. S. Sorensen described the use of pressure blast air-cooling of the McDougall roasters at the Steptoe Valley smelter, by means of which the tonnage handled has been raised to 90 per furnace day, with an elimination of 60 per cent of the sulphur content, while at the Great Falls plant, Mr. A. E. Wheeler has raised the daily tonnage of similar roasters to 75 tons per day, with a sulphur elimination of 75 per cent, the output in this case being chiefly limited by the mechanical strength of the mechanism. The present tendency of roasting practice thus being toward increased tonnage, the Thiogen process, in which roaster output is limited by the necessarily high sulphur content of the gases, will be obliged to exhibit compensating advantages to the managerial eye to secure adoption. The inventor and his associates deserve high commendation for the large amount of careful research they have devoted to the solution of a pressing metallurgical problem.

Wanted: A New Deal

As a further contribution to the discussion regarding the California State Mining Bureau, we present this week the full report of the State Board of Control, the reply of the Trustees of the Mining Bureau, and a careful review of the situation by Messrs. C. W. Merrill, Albert Burch, M. L. Requa, John H. Mackenzie, and F. W. Bradley. This review leaves little to be said concerning the removal of Mr. W. H. Storms from the position of State Mineralogist. Mr. Storms is fortunate both in his facts and his friends, and with this complete vindication the personal side of the matter may well be dropped. A capable officer and a well intentioned state administration came to a parting of the ways because of a bad system and impossible conditions. Experience has made abundantly clear the fact that it is impossible to make the Mining Bureau fulfil the expectation of the mining men of the state under present conditions. There is entirely too much point in the criticism made by the Board of Control; our objection is to the use made of that report. It is always more important, however, to change a wrong system than to assess blame among individuals. As it now stands the state is in the position of a man who owns an expensive automobile, refuses to furnish gasoline, and then blames the chauffeur for failure to progress. We are willing to believe that the Trustees on the Board have done what they could and that the new State Mineralogist will serve the state to the best of

his ability, but there is hopeless confusion of authority and lamentable lack of funds for certain most important purposes. The sensible course is to abolish the present institution and create a new non-political board of small membership, giving it full charge of the work with definite authority and responsibilities. Such a board, with a moderate increase in funds, could more than double the useful work of the present bureau. Field studies are what is most needed, and in the reorganized bureau should be centred all the geological work of the state. The Water Commissioners in the oilfields, the Highway Commission, the State Engineer, the proposed new State Water Commission, all these and many other state officers need the advice and help of a competent geologist, and in aiding existing bureaus, as well as in direct stimulation of the mining industry, there is a large field for usefulness. California has been put to shame too long by maintaining a simulacrum of a mining bureau. It is time to entirely reorganize or abolish the institution.

To Voters of the Institute

Members of the American Institute of Mining Engineers have been so bombarded with letters and circulars this year that many have become hopelessly confused as to the issues involved. For the benefit of those who have not had time to study the situation independently, it seems worth while to present in the briefest possible space the results of our own study.

As is generally understood, the Institute was found by the Committee of Five to be living beyond its income, and its business to have been conducted somewhat loosely. Happily, attention was called to the situation in time, and, thanks to the active work of Mr. James Douglas in soliciting contributions to the land fund and the good work of the present Board of Directors, the Institute entered 1913 in excellent financial condition. A continuance of vigilant care and a reasonable participation by members in its responsibility as well as its benefits will assure sound financial conditions in the future. Another result of the investigation was the proposal to change the articles of incorporation, the constitution, and by-laws, to the end of securing more general participation of the members and better business methods in the routine work of the Institute. The articles of incorporation have already been changed and, whatever may be done with the new constitution, an enlarged Board of Directors must be elected in February. Since the new constitution, if adopted, will abolish the Council and centre all responsibility on the new Board of Directors, it is desirable to change the order of business at the annual meeting so as not to elect a Council that is immediately to be abolished. We urge all members to execute proxies in favor of the new constitution and the new order of business.

In addition to the constitution itself, a separate amendment has been proposed providing for a class of Fellows of the Institute, to include the older and more experienced members. As it stands we believe this should be defeated. There is no good purpose to be served by decorating a select circle with an honorary title, and 'Fellows' can do no good unless given specific duties and powers. If the men properly entitled to the rank were to be permitted to consider matters and formulate expressions of opinion on professional matters, the body could be made an extremely useful adjunct to the work of the Institute. This, however, is not now proposed and any other basis for fellowship would, we think, result badly. A second reason for opposing the amendment is that the real work of a body of Fellows would be the same as that now attempted by the Mining and Metallurgical Society. Negotiations for affiliation of the Institute and the Society are now being conducted, with every prospect of a successful conclusion. With such affiliation and the resulting enlargement of the society the field for a class of Fellows will disappear.

The other amendments proposed relate to details of business conduct. Many consider it better to leave such matters to the Directors, but the fact that the proposals come from Messrs. C. R. Corning and George C. Stone, after their thorough study of conditions and with their large business experience, throws the burden of proof on those who would oppose them. It is certainly important that the Assistant Treasurer, who in practice has heretofore paid most of the bills, should not hold any other office. Any plan which permits the man who incurs an expense to approve his own bill, draw the check, and receipt the account, is open to grave objections. This has happened in the past, and the proposed change would make it impossible in the future, though there are other ways to meet the situation.

Men as well as methods are important in the conduct of any business, and therefore the nominations for office should be scrutinized with great care. The official ballot prepared by the nominating committee has our entire approval. It includes representatives of the profession from all parts of the country, and, we are permitted to say, no name was placed on the ballot until after it had been made sure that, if elected, the new officer would devote adequate time and real attention to the service of the Institute. An opposition ticket has been nominated by petition. It proposes for re-election the present secretary and all the present members of the Council and Board of Directors who are eligible to reëlection, adding to the list enough to fill out the new Board. For reasons given in full in our issue of last week, we are opposed to the reëlection of the present Secretary, and with the friendliest possible feeling for the retiring members of the Board of Directors and Council, many of whom we count among our personal friends, we think it will be easier for new officers to make changes than for old ones. The nominating committee has provided that more than half of the new Board of Directors shall be drawn from among those now serving the Institute as Director or member of the Council, and a number of others nominated have previously so served. No nominating committee in years has taken so much pains to select men to represent the entire membership of the Institute, and our advice to members is to vote the official ticket, and vote it straight.

Treatment of Concentrate at the Goldfield Consolidated Mill

By J. W. Hutchinson

*By means of iron goose-neck flues, the gases from the roasters at a temperature of 450°F. are delivered to a concrete dust-flue 264 ft. long, having a cross-section of 50 sq. ft. From this flue, 20,700 cu. ft. of gases per minute escape through a vertical steel stack, 100 ft. high and 54 in. diam., having a temperature at the base of the stack of 325°F. The velocity of the gases in the dust-flue has been determined with a Hiram anemometer to be 7½ ft. per second. The escaping gases are white, and no dust is visible to the eye. Measured quantities filtered through woolen bags indicate a stock loss of less than ½%. This figure is taken as a total loss in handling, roasting, conveying, etc., and added to the tailing loss. One per cent of the material roasted is collected in the dust-flue and has a value of 20% more than the material roasted. Apparently, all the dust is made in the feed-end of the furnace, since this dust contains 15% sulphur. Approximately 80% of the dust recovered settles in the first 150 ft. of the flue. The flue is built on the slope of a hill and at the top it is 79 ft. above the hearth. As can be seen from the drawing, a drag-chain conveys this dust down the flue, from which it is discharged through wrought-iron gates into a sump. Water is added and the resultant pulp elevated back to the Kelly press storage tank for filtration and mixing with the regular feed. The loss and inconvenience through handling this fine material dry is thus avoided.

Analysis of Roasted Product

Mesh.	Per cent.
+100	12.5
+150	15.5
+200	25.5
−200	46.0
Composition.	
SiO_2	54.60
Fe_2O_3	32.20
S (as sulphide)	0.15
S (as sulphate)	0.75
Al_2O_3	3.00
CaO	0.20
MgO	0.13
Cu	0.60
Te and Se	0.19
Sb	0.07

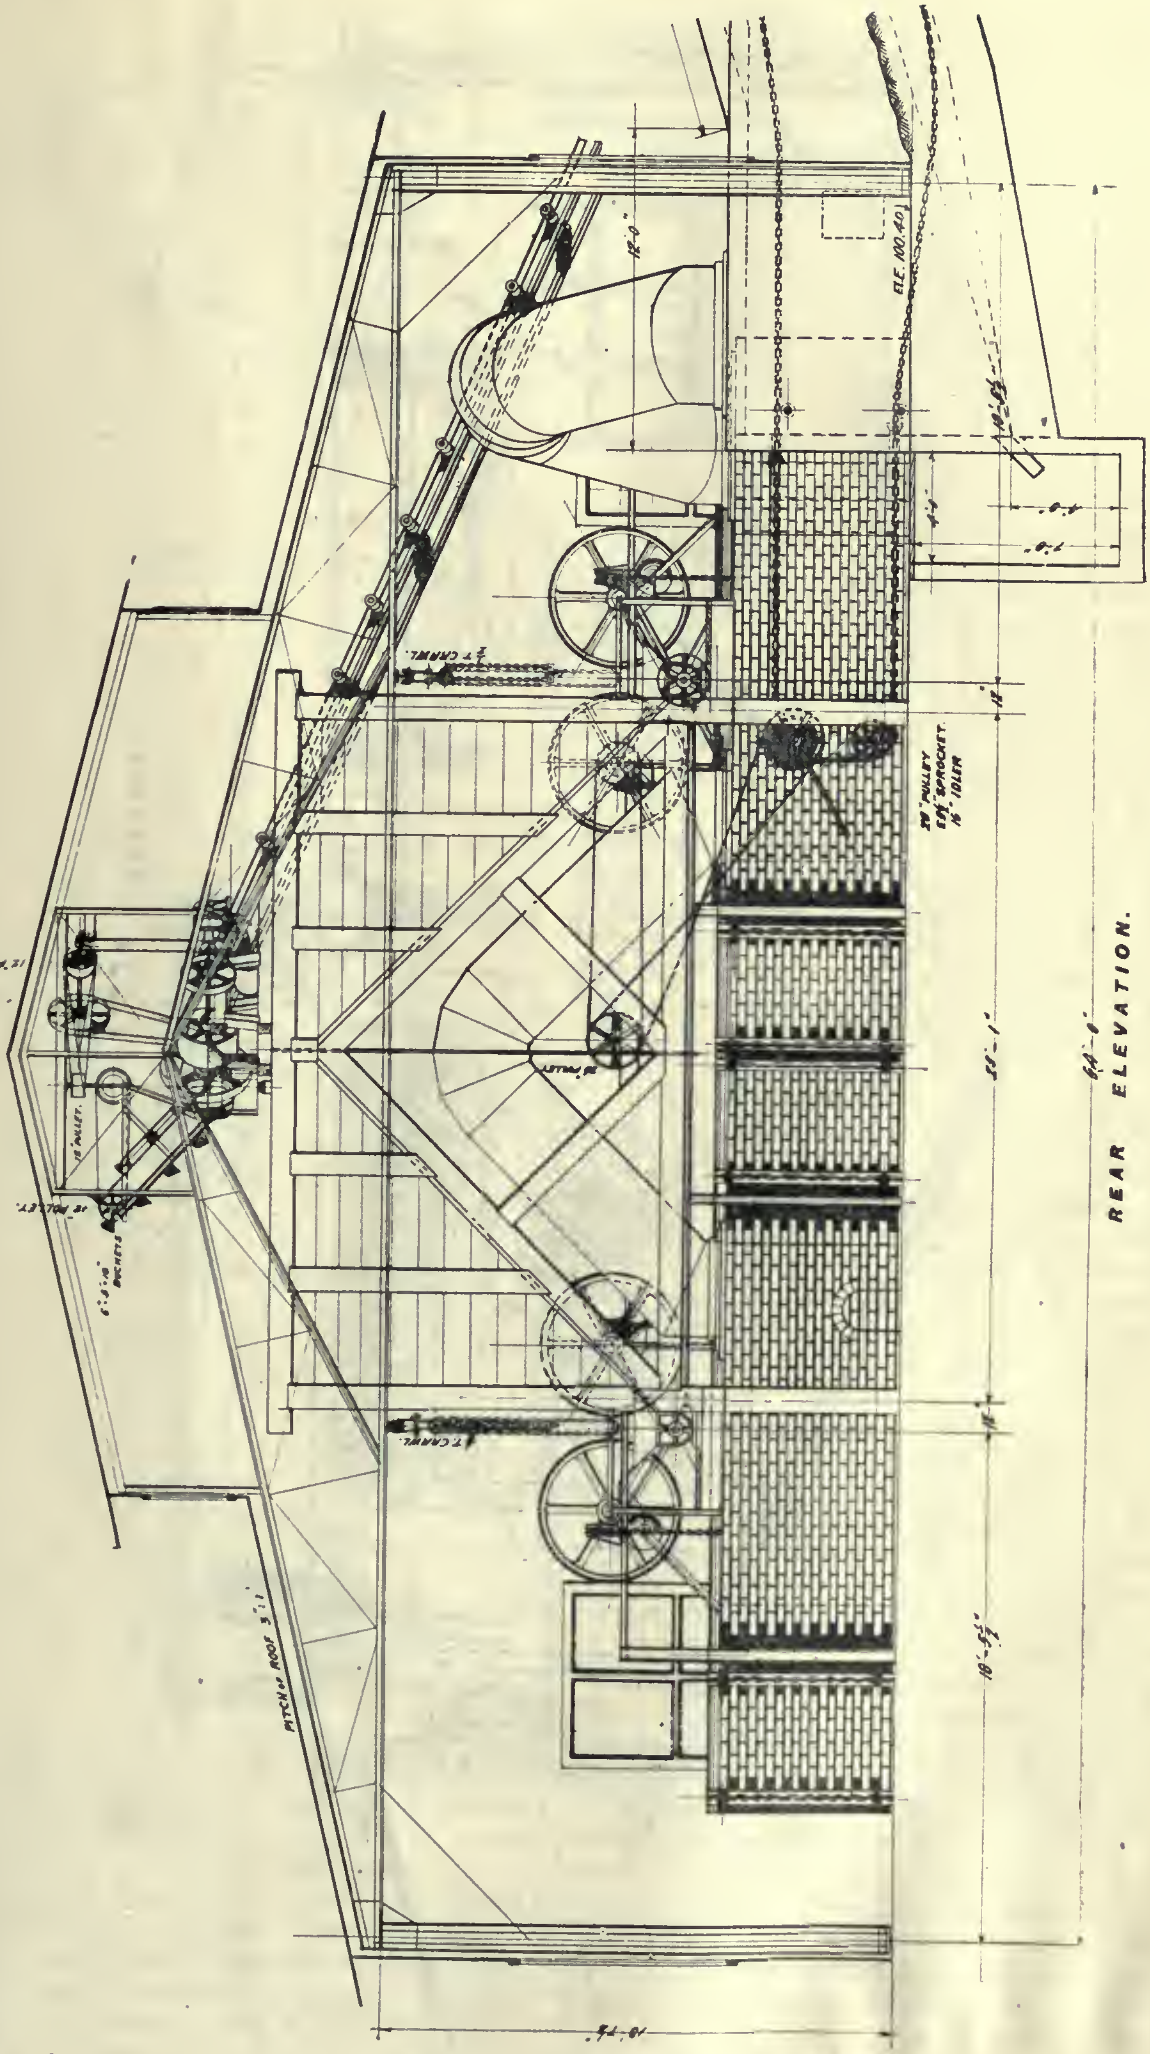
In line with the last rabble on each furnace there is a cast-iron discharge chute on one side of the furnace only, set at an angle of 45°, through which the roasted material is delivered to a drag-chain conveyor. This conveyor runs at a speed of 45 ft. per minute and elevates the material up an incline of 15° to the feed spout of a Baker cooler. As can be seen from the drawing, the original device for conveying the hot concentrate was a water cooled screw-conveyor. This was decidedly unsatisfactory and was discarded in favor of the drag-chain. This chain does good work, requires no repairs, and is very satisfactory. The drag-chain, sprockets, and all movable parts are housed in a brick conveyor-way built up 2 ft. above the floor line and covered with ¼-in. plate, and no dust escapes into the building.

The Baker cooler is a sheet iron cylinder, 5 ft. diam. and 22 ft. long, carried at each end on a hollow trunnion bearing, through which the ore is fed and discharged. It revolves with about 40° submergence in a water-tight concrete sump, to which the cooling water is added. Cooling is accomplished through the evaporation of water on the surface of the shell. The cooled ore is discharged dry at about 100°F. into a small concrete sump, over which there is a tight cover, where water is added to wash it to the boot of a 14-in. belt and bucket elevator with 12-ft. centres. Much difficulty was experienced in elevating the material after wetting, due to the soluble copper compounds in the roasted product. Cast-iron centrifugal pumps would not last for this reason. Phosphor bronze pumps were too soft to resist the abrasive action of the pulp. A temporary belt and bucket elevator with steel parts lasted a couple of weeks. Finally, by using brass pulleys, shafting, cups, bolts, and a canvas belt, the elevators have been made fairly satisfactory. The small elevator in the roaster building delivers the pulp to the boot of a second elevator of similar construction placed in the treatment plant, which delivers it to three 20 by 12-ft. combined collecting and agitating-tanks, fitted with the adjustable square shaft agitator. The sole plates, holding bolts for these agitators, are made of brass, and the shaft is protected from the corrosive action of the washes by means of a lead covering. The tank connections in these tanks are brass.

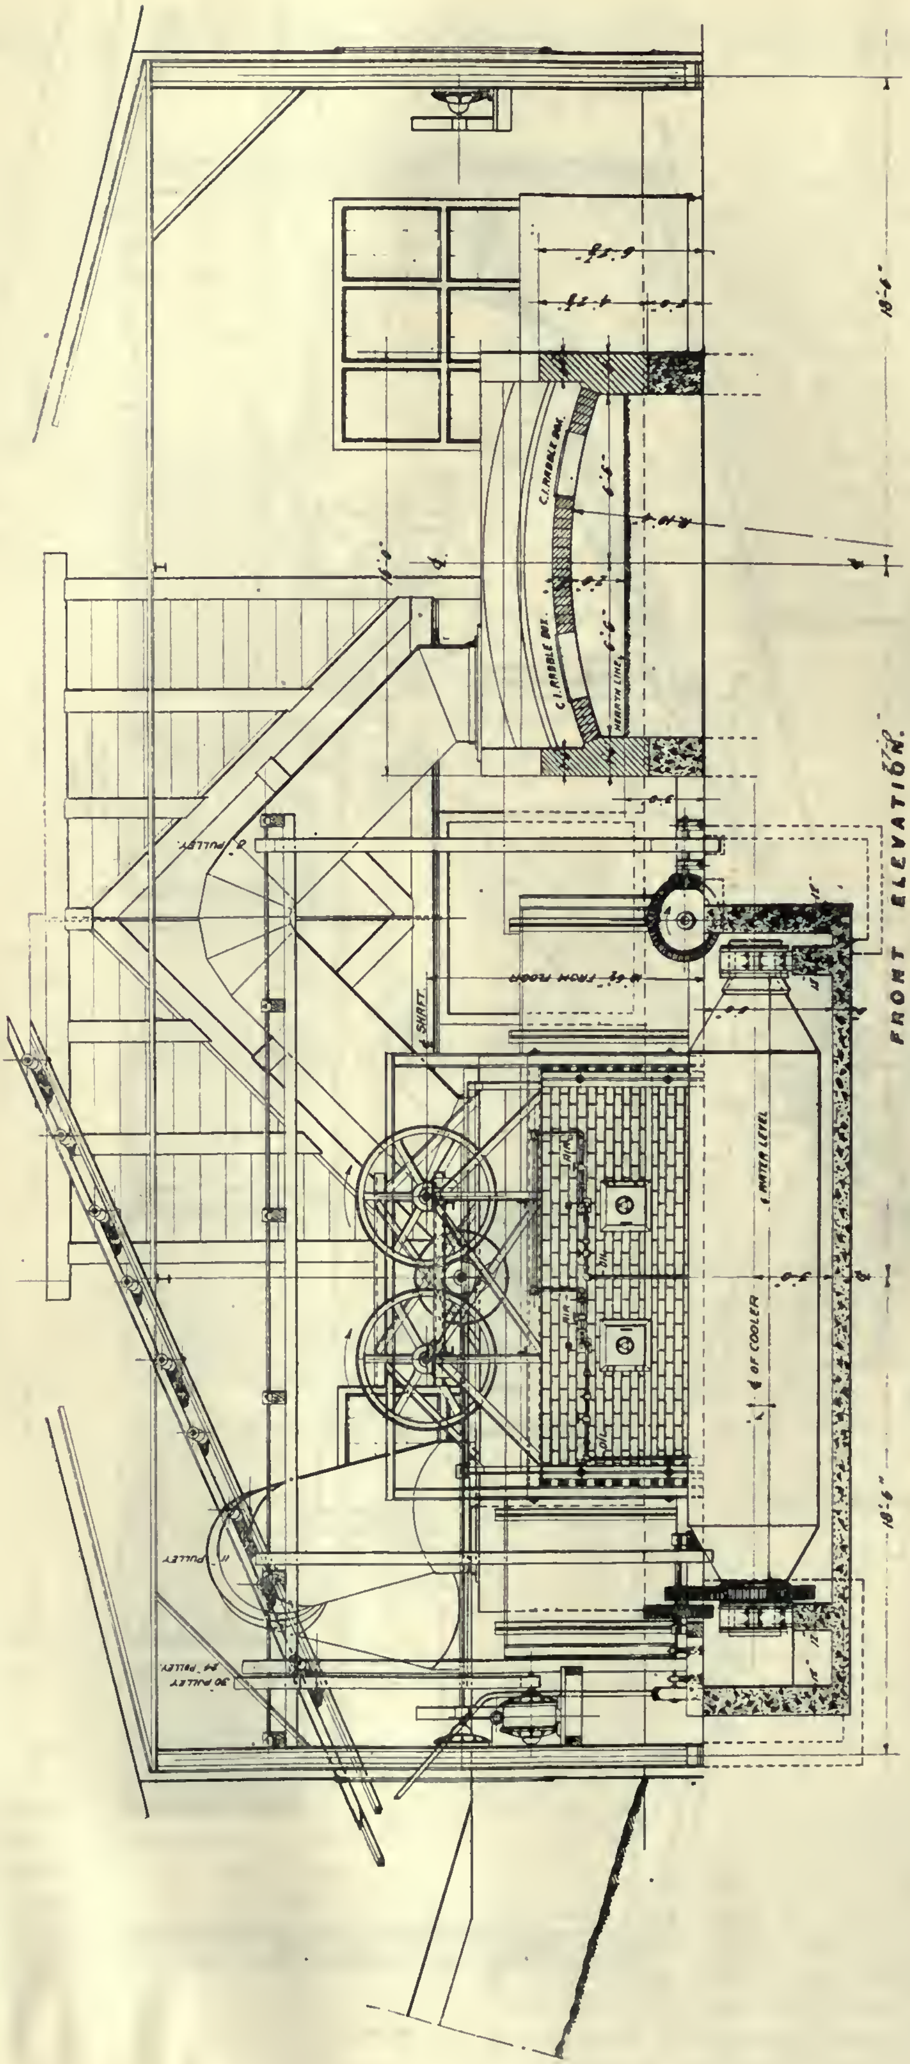
The roasted concentrate is delivered to one tank for 24 hours. The collected charge is then settled and decanted to a consistence of 1 to 1 and sulphuric acid added in the proportion of 20 lb. per ton of concentrate. Agitation with the sulphuric acid is continued for eight hours. Water is then added to fill the tank and the charge allowed to settle. When clear, the wash is decanted and the tank re-filled with fresh water. Four water washes are given, equivalent to eight tons of wash water per ton of concentrate. All washes are passed through two redwood tanks filled with excelsior for clarifying, and overflow from these tanks to six redwood tanks, 10 ft. diam. and 5 ft. high, arranged in series for recovering the copper. These tanks are kept filled with cyanide tins and all kinds of scrap from the mill. The average copper content of the washes is 0.4 lb. per ton, and 70% is recovered.

The thoroughly washed charge is neutralized with lime, and by means of centrifugal pumps elevated to one of four Pachuca agitators, 14 ft. diam. by 25 ft. 6 in. high. Experimental work showed that only 10% of the gold of the roasted concentrate could be recovered by amalgamation, but that no increase in final extraction could be obtained by this step, and for this reason amalgamation was not deemed necessary. The only explanation known for this peculiar

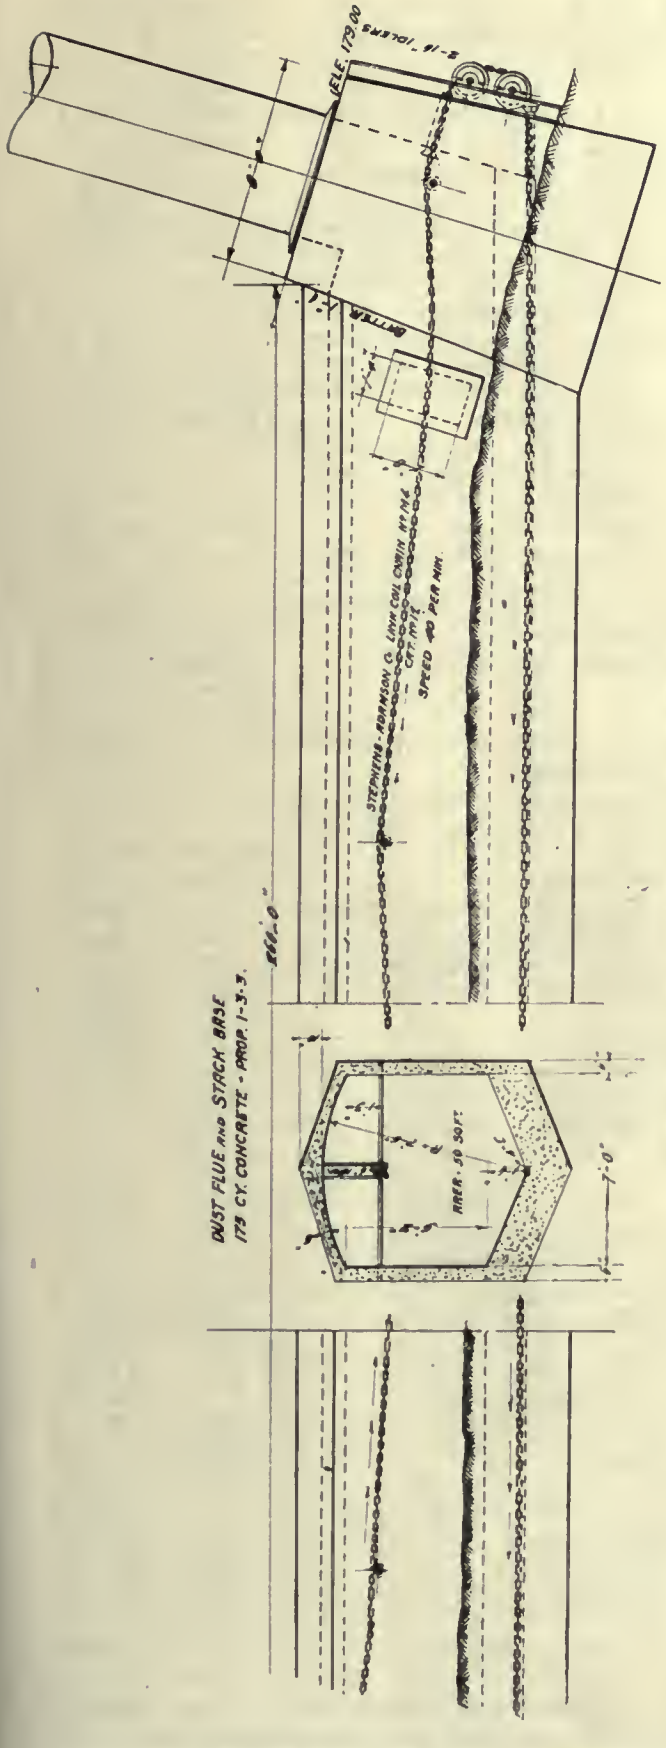
*Continued from p. 170.



CROSS-SECTION OF FURNACE SHOWING DISCHARGE END.



CROSS-SECTION OF FURNACE SHOWING FIRE-BOX.



LONGITUDINAL AND CROSS-SECTION OF DISCHARGE DEVICE.

action of the gold is that the antimony, bismuth, tellurium, and selenium (though present in minute quantities only) with which the gold is so intimately associated, are not completely volatilized in the furnace, and form a film of their oxides on the surface of the gold particles. The same explanation will account for the failure of the rich roasted concentrate to yield so high a percentage of its gold to cyanidation, as can be recovered from the two-stage treatment. The following comparison is interesting:

	Au, oz.
Assay before roasting	12.25
Assay after roasting	15.35
Assay after 64 hr. treatment	0.66
Percentage recovered	95.7
Assay of raw concentrate	11.60
Assay after 48 hr. treatment	0.96
Percentage recovered	91.7
Assay before roasting	0.96
Assay after roasting	1.17
Assay after 32 hr. treatment	0.107
Percentage recovered	92.6
Percentage of original gold recovered by raw treatment	91.7
Percentage of original gold recovered after roasting	7.6
Total percentage recovered	99.3

It is a fact proved by repeated experiments and by working tests that no more gold can be amalgamated from a 10-oz. roasted concentrate than can be amalgamated from the same material in its raw state, and that roasting the rich concentrate does not materially expedite the dissolution of the gold. It seems probable that some of the gold is partly encased in the sulphides of the volatile metals, but presents some surface to which the cyanide solution has access. After roasting, it is probable that the gold may be entirely covered with a film of the oxide of such metals, which must be removed before dissolution can proceed. Since these metals do not interact with alkaline cyanide, their removal is doubtless accomplished slowly by the alkali of the solution, and this may account for the prolonged treatment which the roasted material requires. This theory is offered merely as an explanation and the ideas of others would be appreciated.

In the above mentioned Pachuca tanks the roasted charge is agitated for eight hours in a 2-lb. solution of cyanide, containing 1.2 lb. CaO as protective alkali. At the end of eight hours, agitation is discontinued, the charge settled, decanted, and reagitated with a freshly precipitated solution in the same manner as described above in the treatment of the raw concentrate. Five periods of agitation followed by decantation are given, and a total of three tons of solution per ton of concentrate is decanted. Consumption of chemicals amounts to 4½ lb. cyanide and 2 lb. lead acetate per ton of concentrate. After agitation is completed, the settled charge is delivered to a storage tank 18 ft. diam. by 8 ft. high, fitted with the adjustable square-shaft agitator. Placed centrally in the bottom of this tank is a 4-ft. cone with pipe connections through which the thickened pulp is fed to a 5 by 18-ft. tube-mill. The pulp issuing from the tube-mill is elevated by means of a belt and bucket elevator back to the above mentioned storage tank. This circulation grinding is continued for 16 hours, at the end of which time 95% of the material will pass a 200-mesh screen. From 80c. to $1.25 per ton is removed in this circuit. Regrinding before agitation with cyanide was the original plan, but had to be discontinued on account of the inability to settle and decant the finely pulverized ore. Since the change of solution increases extraction and since the final tailing is sent to the mill proper for filtration, it was decided to re-grind after the greater part of the gold had been removed.

After re-grinding, the pulp is delivered by means of a centrifugal pump to the filter storage tank in the mill proper, mixed with the mill pulp, filtered, and sent to waste.

Since precipitation and refining are accomplished in the manner described in the former article, it is not necessary to give the details of these operations here. Extraction and costs are shown below:

COST PER TON

Labor		$1.02

COST OF ROASTER PLANT

Contract for:		
2 Edwards duplex 54-spindle roasting furnaces, 112 by 13 ft. inside, erected on side walls furnished by the Goldfield Con. M. & T. Co., which side walls extend to within one foot of hearth line	$33,485.17	
1 Baker cooler, 5 by 22 ft., erected on foundations furnished by the Goldfield Con. M. & T. Co., complete with driving mechanism, etc.	3,400.00	
Excavations for foundations	1,897.00	
Concrete in foundations, 218 cu. yd. at $14.25	3,106.50	
Total cost of furnaces and cooler erected		$41,888.67
Dust-flues and stack:		
Dust-flue of concrete, 264 ft. long, 6 ft. high, 7 ft. wide; walls 7 in. thick, bottom 10 in. thick with 24° slope to centre; roof 8 in. thick, arc of 10 ft. circle; concrete reinforced with ¼-in. rods, spaced 1 ft. apart both horizontally and vertically, and with a steel cable laced through these rods; total cost	$ 5,500.00	
Stack of American ingot iron, 100 ft. high by 54 ft. in diam., weight 10,620 lb., invoice $573.60, freight $519.60; total cost	1,093.20	
2 goosenecks, 60-in. diam. and 42-in. diam., weight 4480 lb., invoice, $416.00, freight $248.49; total cost	664.49	
Supplies used in erection	375.20	
Labor	311.48	
Total cost of dust-flues and stack		$ 7,944.37
Steel building:		
65 by 158 ft., containing 10,270 sq. ft., at $7398.23 erected in Goldfield	$ 7,398.23	
Foundations	1,213.87	
Covering of 'asbestos protected metal,' weight 1¾ lb. per sq. ft.	3,538.84	
Labor for laying asbestos covering	700.00	
45 windows in place at $10 each	450.00	
		$13,300.94
Ore-bins:		
2 wooden ore-bins, 1620 cu. ft. cap.:		
Supplies	$ 721.26	
Incidentals	55.93	
Labor, erection	311.70	
Total cost of ore-bins		$ 1,088.89
Transmission, elevating, and conveying machinery:		
Line shafting, etc.	$ 2,069.87	
Labor, erection	1,858.55	
Total cost		$ 3,928.42
Miscellaneous expense:		
Labor	$ 530.50	
Supplies	1,086.81	
Total miscellaneous expense		$ 1,617.31
Electrical work:		
Labor	$ 163.00	
Supplies	527.56	
Total electrical work		$ 690.56
Total roasting plant proper		$70,459.16

COST OF TREATMENT PLANT

Superstructure:		
Wooden building, 44 by 48 ft., including lumber, concrete, and covering	$ 3,109.13	
Labor (erection), excavating, moving dumps, etc	2,447.48	
Total cost of superstructure		$ 5,556.61
Pachuca agitation:		
2 steel Pachuca agitators, 14 by 25½ ft., weight 32,860 lb.:		
Invoice	$ 1,225.00	

Freight	384.46

Total cost of treatment plant		$18,488.08
Total cost of roasting plant		70,459.16
Total cost of treatment and roasting plants		$88,947.24

Suspension Colloids

At a recent meeting of the Faraday Society, in London, Ruisdale Ellis read a paper entitled 'A Neutral Oil Emulsion as a Model of a Suspension Colloid.' The interface potential at the surface of the oil globules of an emulsion was measured by means of a mircoscope slide apparatus. The interface potential was found to be little affected by organic impurities in the oil, but to be altered enormously by acids, and to a lesser degree by alkalies. The maximum interface potential was found to correspond to a concentration of about 0.001 N alkali, and this was found to be the point of maximum stability of the emulsion. Surface tension measurements showed that the stability did not depend on the surface tension, but on the interface potential.

Determinations were made of the concentrations of salts with mono-, di-, and tri-valent kations required to just neutralize the charge on the oil globules. The ratio of these concentrations was found to form a geometrical series agreeing with that obtained by coagulation experiments. The coagulation of oil emulsions by colloidal ferric hydroxide was next tried, and it was found that the oil was completely precipitated within two well defined limits on either side of the iso-electric point of the oil emulsion. The coagulation appears to be due to surface precipitation effects taking place between the oil globules somewhat analogous to the condensation of water-vapor on surfaces of various curvatures.

In the subsequent discussion E. Hatschek stated that the size of the oil globules in Mr. Ellis's experiments was about 2 η, which was of course very much larger than anything in suspension colloids. It is difficult to realize how the electrical 'double-layer' would prevent collision between the globules; the theory is useful mathematically but very obscure physically. Whetham's theory with regard to the ratio of concentrations of salts with mono-, di-, and tri-valent kations required to neutralize the charge on the oil globules is untenable, as, for one thing, it is based on the assumption that the particles are stationary.

A. W. Porter controverted a number of the remarks of the previous speaker. Whetham's theory merely depends on relative motion taking place. The coming together of two globules with 'double layers' would have the effect of mutually disturbing the perfect uniformity of their electric charges, and then the particles would repel one another. F. G. Donnan, in a written communication which was read to the meeting, pointed out that no distinction could be made between suspensions and emulsions if based merely on the liquid or solid state of the disperse medium. The oil emulsions behaved as typical suspensions, forming a very striking model of a suspension colloid. Bredig's 'Lippmann Effect' theory of the stability of suspensions was not borne out by Mr. Ellis's results. Further work on emulsions is being carried out in the Muspratt laboratory.

The great interest of the subject in connection with the theory of oil flotation processes now largely in use for ore separation was remarked by H. M. Ridge. G. Senter referred to some recent work of Freundlich in which geometrical ratios in the coagulating effects of mono-, di-, and tri-valent kations were not observed. He agreed that the author's work did away with any real distinction between suspension and emulsion colloids. E. Feilmann said it had long been known that slightly alkaline media favored the formation of stable suspensions, but he gave instances where slightly acid media had the same effect. He criticized the author's suggestion that dyeing might be due to capillary coagulation of the colloidal dye.

Ore of the Braden mine, in Chile, consists of chalcopyrite, bornite, secondary chalcocite, cuprite, metallic copper, and carbonates and silicates of copper. It had proved difficult to treat by ordinary wet concentration methods, the recovery being only about 60%. Tests by the Minerals Separation flotation process resulted as follows:

	Tons treated.	Cu, %.	CuS, %.
Heads	2726.2	2.61	....
Concentrate	274.1	20.82	....
Tailing	2452.1	0.56	....
Calculated recovery		80.00	87.40
Actual recovery		80.20	87.65

Consumption of reagents was: Sulphuric acid, 3.57 lb. per ton; Texas and wood-tar oils, 2.33 lb. per ton.

Labor in the Mines of Western America

By H. F. Davis

If a mining engineer were asked to classify the miners of America, he would probably do so with reference to the mining district from which they come, probably beginning with Cornishmen, then naming the other districts that have furnished us with so many of our present miners, such as Michigan, New York, the New Jersey iron and copper mines, the Pennsylvania anthracite mines, lead and zinc mines of Missouri, the silver and gold mines of Virginia City, etc. An old-time Western quartz miner would probably nickname the same men 'Cousin Jacks,' 'Peerless men,' 'Shads,' 'Jersey plugs,' 'slate-pickers,' 'Missourians,' and 'hot-water plugs.' This does not, by any means, include all the districts that have furnished miners for the Western mines, for every country has its representatives: but it includes the most famous among them. Of course, the ubiquitous Irishman is found in every delegation of English-speaking miners, and many of the best are Irish.

Cornish Miners

It is but natural that many of our best miners should come from Cornwall, as that country has been engaged in deep mining from prehistoric times to the present day. Generation after generation went into the mines when mere children, and with them mining was a permanent occupation. As their mines began to be worked out the Cornishmen sought other mines, because they knew no calling but mining, and this search has taken them into every country where any considerable amount of rock-mining is done. They are seldom found in the coal mines. They were not, as many of our American miners are, inclined to seek temporary employment in the mines on account of high wages, with the expectation of engaging in other lines when they had made a 'stake.' (A Cornishman's idea of a 'stake' is a job in a mine that employs other Cornishmen for bosses.) The fact that Cornishmen go into the mines so young, usually working with the father or older brother, accounts for their proficiency as miners, since mining is a matter of experience and practice. A knowledge of it is never inherited, and the miner direct from Cornwall is not nearly so proficient as his brother who has spent no more time underground but has worked in several districts. The Cornishman's reputation is not what it was twenty or thirty years ago. He follows too closely in the footsteps of his father and often stubbornly refuses to recognize the merit of other than Cornish methods.

Among the principal American mining districts none has furnished so many good miners as the iron and copper districts of Michigan. The descendants of the foreign miners of that locality are widely scattered over America, play an important part in many mining communities, and are usually equally good at hammer and machine work. The reason for this versatility of the 'Peerless men' is found in the many different conditions that obtain in the Michigan mines. They have both hard and soft iron ore as well as copper and some gold and silver, and the methods include both hammer and drill and machine work. Further, the young Michigan miner of the past usually hoped to emigrate to the mining districts of the Rocky Mountain region in order to obtain higher wages, and, learning from those who had preceded him that it would be of advantage to him to be able to do either hammer or machine work, he usually endeavored to perfect himself in both while at home. (The name 'Peerless' has no reference to the ability of the Michigan men. It is the name of a tobacco largely used by them; which, by the way, is not manufactured in Michigan, but is another of the products which has added to the fame of Milwaukee.)

What has been said with reference to the Michigan miners applies largely to those from New York and New Jersey also, though being farther away and fewer in number, fewer of them having emigrated westward. The miners from the lead and zinc districts of Missouri are not as proficient as those from the other localities mentioned, because their methods of mining differ and the inducements in the way of wages have not been, in the past, such as to attract miners from other localities with new methods and ideas. However, in more recent years, this fault has been recognized and is being corrected by the importation of bosses and miners from other fields.

Hand Men and Machine Workers

The miners of Western North America are derived from many sources, but they are all largely influenced by the methods of other districts. All European countries are represented among them, and, owing to the varied character of the substances mined, practically all methods are used. The miner of the Rocky Mountain regions must be proficient in many methods to be classed as an 'all-round' miner, and is never classed as such by the veteran unless he can drill single and double-hand and with a machine, as well as do all ordinary timbering. However, with the decadence of hammer and drill work in the past twenty years, there are many good machine miners who cannot do it. There are still 'old-timers' who cannot do machine work, though they are few and usually are men who work at mining only to make a 'grub stake' and not as a permanent employment, or men who prefer the small isolated mining districts to the larger ones.

The Cornishmen are always good hammer men, at both single and double-hand work. They are not, as a rule, good machine men. Some of the best single-hand men are Italians, but I have never seen a good machine-man among them. Hammer work is a matter of practice; machine work is a matter of resourcefulness, skill, and strength. The more intelligent miners always make the better machine-

men. However, it is useless to attempt to judge miners by nationality or birthplace. The best miners are those restless mortals who spend their lives traveling from one place to another, seldom spending more than two or three months in any one mine, though this type may not be the most desirable. It frequently happens that the 'home guard,' as the traveling miner contemptuously calls the fellow who stays in one place, is more satisfactory than the 'hobo' miner, as the traveler is called. This is especially true in those mines where the duties of the miner require a relatively small amount of drilling and more pick, shovel, and timber work, because proficiency in such mines is more easily acquired. In such cases the timbering is usually done by a man more experienced than the average miner.

Mixed Crews

No mine foreman ever got the best results possible by employing men of one class only, as a mixed crew always gives better results, because each is quick to appropriate any practice of the others that can be used to advantage, and a spirit of rivalry more often obtains than where one class only is employed. Then, too, labor troubles are less likely to occur. The introduction of southern European laborers, except Italians, into the Western mines, is of comparatively recent date. Twenty years ago it was unusual to find one among the crews of a mine, while today some mines employ them in large numbers chiefly as shovelers and carmen, or in such places where it is difficult to get the more intelligent miners to work.

They seldom make good miners, and it is doubtful policy to employ them in any considerable number, if at all. The management that employs them because they will work for lower wages follows a short-sighted policy, as they are very inefficient, unless distributed among the better men in such manner that they can be directed to some extent by those with whom they work, and this always causes dissatisfaction among the better men. Besides, where it is necessary to pair men, as it frequently is, two good miners will always do better work together than if each has a poor partner. This is especially true on machine work, where two men are required for the operation of one machine. In such cases it is customary for a certain amount of work to be required of each crew such as, for example, to drill a round of 5-ft. holes in a drift, and with an experienced man and a greenhorn it usually devolves upon the experienced man to do much more than his part of the work. This he will do for a few shifts, but it usually results in the experienced man 'pitching' his job, for it is a kind of unwritten law among miners to never complain of a partner or the place in which one is put to work. The good miner, when dissatisfied with either, will enter his complaint by quitting. In districts where a large supply of miners is available, it is unnecessary to pair experienced and inexperienced men, and it is seldom done by the experienced shift-boss. When it becomes necessary, on account of the scarcity of men, great care should be used or it will result in the good men quitting. The plan of working one experienced man and a helper at a different rate of pay has never proved satisfactory from the miner's standpoint, and only in those cases where good machine men are scarce has it proved satisfactory to the management. It is now customary in nearly all mines where two-man machines are used, to pay both men the same wages.

Some Things Which Make for Efficiency of Labor

Labor is always more efficient in those districts where there are more miners than jobs, because there the foreman can pick his men and can quickly replace any inefficient ones. In such cases, one can but be impressed by the extreme youth of the men employed in most of the large mines. Underground work is a young man's occupation, and the miner past forty is seldom wanted. In very exceptional cases only is such a man able to keep the pace set by the younger miners in the larger mines, especially where machine work is the rule.

The most important factor in labor efficiency is a plentiful supply of young miners, preferably of different origin. To secure this supply, three things are essential: good wages, good board and lodgings, recreation for the men when off shift. The lack of any one of these is fatal, and the district that supplies them always has an abundant supply of labor regardless of everything else. It has been demonstrated time and again that the superintendent who tries to operate a mine and pay less than the regular wage scale of his region does not increase the efficiency of his labor thereby, yet there are still some who think they can do it. In his admirable work, 'The Cost of Mining,' J. R. Finlay gives some figures relative to this feature that might be studied with advantage by all such. It is refreshing to a miner to find a writer who so thoroughly appreciates this phase of the labor question and who so fairly expresses it. It is the opinion of all those best able to judge that cheap labor means poor labor.

Boarding-Houses and Lunch Buckets

One of the serious questions that confronts every superintendent of an isolated mine is that of the boarding-house. No company boarding-house ever satisfied the miner, and none ever satisfied the superintendent unless he had a financial interest therein. They should be abolished in every case possible, and it is nearly always possible on permanent operations. Where it is absolutely necessary to run a company boarding-house, it is of first importance that the miners' lunch pail be given proper attention. No other feature of the boarding-house is so prolific of complaint from the miner as the 'lunch can.' The lunch is nearly always eaten underground, frequently in foul air, dust, and powder smoke, and often, far in the night, when the 'super' is dreaming of low costs and large dividends, the miners are grouped in some evil-smelling cross-cut, their lunch-cans between their knees, eating from grimy fingers the lunch for which too frequently too much is deducted from the monthly check. That lunch is the fuel which must develop the energy for the remainder of the shift, and, with the management, it is a matter of policy, not sentiment, to see that that fuel

is provided in quantity and quality which shall be satisfactory to the engine that consumes it. Here, too, over the lunch-cans are discussed questions of policy that frequently have an important bearing on those low costs and large dividends of which the 'super' sweetly dreams, and the views expressed would often be illuminating to him. Those operations that depend upon the company boarding-house and store for their dividends usually come to grief.

Recreation and Quarters

The problem of recreation is only solved satisfactorily in the larger districts. However, at the small isolated 'bunk-house' mines, some kind of a recreation room should be provided where the miners can congregate when off shift. This should be separate from the bunk-house, but may be used as a 'change-room' where the miners can dry their clothes and wash them, if necessary, without disturbing others. Newspapers should be furnished when possible and such magazines as are available. Even the advertising literature that comes to the office is acceptable, and anything of the kind, if taken to the miners by the superintendent in person, will do much to break down the feeling of antagonism that too frequently prevails between miner and manager.

Quarters for the mine bosses should always be distinct from those of the men, for familiarity when off shift leads to familiarity in the mine which is not conducive to the best results and too frequently the boss of the mine is looked upon as the boss of the bunk-house. This should be so only so far as generalities are concerned. The management should recognize that the miner's time belongs to the miner when 'off shift', even though that time is spent in the company's property, and no rules for his conduct should be promulgated. In a case which occurred in my experience, a New York City manager of a California mine twenty-five miles from a railroad attempted to prevent the miners from indulging in a favorite card game in the company bunk-house. He broke up the card game, but he lost a crew of good miners in an area where good miners were scarce, and also lost the best foreman in that district. The foreman quit because he said he had practically every good miner of that district in his crew, could not get another crew like it, and hence could not get good results. The manager found that with a new crew it cost him about 25% more to keep his mill supplied with ore.

A Day's Work

Another frequent cause of discontent among miners is the boss who does not know his business. To one who does not understand the eccentricities of a miner it might appear that it should make no difference how the work is done, as the miner is paid per shift. This is true to a limited extent only. The miner prefers to have his work judged by the shift rather than by any part thereof. He resents being shown by the boss how to do those things which a miner should know how to do without being shown, such as the proper manner in which to place the drill-holes. An experienced miner will nearly always quit immediately if a boss attempts to 'point his holes for him' or to measure them when drilled. The miner quickly learns when a boss is not a good miner, and his inefficiency is a favorite topic in the bunk-house or at lunch. The report is rapidly circulated that 'he don't know a shift's work when he sees it', and then the miners 'throw off' on him and do less work. The shift-boss more than any mine official should know every possible detail of mining practice.

The expression 'to handle labor' means to direct men at their work, and in my opinion to do that requires a thorough knowledge of both men and the work. A man's success at handling labor will be directly proportionate to his combined knowledge of the men and the work required of them. This knowledge is absolutely necessary to the successful shift-boss, and of but minor importance to the superintendent. The chief duty of a shift-boss is to meet emergencies. He should be able to locate quickly any cause of disturbance of the regular routine of the mine work and to apply a prompt remedy for it. Should a bad 'fall of ground' occur he should be able to handle it in such a manner that the regular progress of the mine will not be impeded; should a machine 'buck' he should be able to quickly determine the cause and apply a remedy so promptly that the round will be drilled by blasting time; should a man get injured he is the one to direct the operations of getting him out of the mine. The young college graduate who tries to break into the mining game as a shift-boss usually imagines that shift-bossing consists of walking through the mine in a pair of laced boots with a time-book in his hip pocket. Fortunately for him this belief is not generally shared by those who hire shift-bosses, with the result that he usually lands in the superintendent's office, sooner or later, dependent upon the intimacy of the relation existing between him and some wealthy member of the board of directors.

I have worked in the mines of some thirty or forty superintendents and for a hundred or more shift-bosses and, with the exception of a few whose duties were more of the nature of general foreman than of superintendent, the percentage of them who graduated from shift-boss to 'super' is so small as to be negligible, while the number of 'school of mines' graduated shift-bosses was still smaller.

College Men and Miners

A word regarding the college man and the miner. One fact usually overlooked by those who argue that, due to the superior advantages of education, a 'school of mines' man, as the miner terms him, should learn to be an expert miner, or a good miner, much quicker than a boy without education is this: the boy with 'no education' usually has an education that is overlooked. It is a physical education acquired by trying to handle tools of various descriptions. His vacations are more often than not spent under the guidance of those who see to it that he works, usually at some kind of arduous labor. When the time comes that he can 'get a job' underground, he usually possesses a physical development different from that of the graduate and also has a better knowledge of tools and their uses. There is nothing more painful to a miner than to watch a young college man try to shovel on a 'rough bottom'; yet there

comes a time to every miner when he has to do just that kind of thing and unless he can do it, he is not a miner and cannot do a miner's work.

It is neither necessary nor desirable that the graduate should learn to be a practical miner. It is unnecessary because the duties of superintendent or manager, for which he has prepared himself at the expense of several years' work and some thousands of dollars, do not require it; undesirable because to learn 'practical mining' well enough to properly do the work of a shift-boss in any kind of a mine it will require not less than from four to five years actual underground work in several different mines. The principles of mining work he is supposed to get at school and in the few trips underground in connection therewith. That is sufficient for his needs. The most valuable education he can get in this connection is one that will enable him to select a good foreman. Some superintendents have been tremendously successful in just this way.

Avoid Conflicting Orders

The superintendent should manage the mine through his foreman and should never hire men for any class of work under his foreman without consulting him. Neither should he give orders to shift-bosses or men except through his foreman, as it causes confusion. The foreman in turn deals with the miner chiefly through the shift-boss. On his daily trips through the mine he will usually avoid giving any orders that will conflict with those of the shift-boss, and if possible the two should make the 'rounds' together. Wherever the miner is concerned confusion of orders is to be avoided with the utmost care. He is usually over-sensitive on this point and 'too many bosses' is a frequent complaint.

By far the best results are obtained by clearly defining each man's duties and holding him responsible for results only. This is especially true as applied to the miner (always supposing that the miner is a capable one), as it puts him on his mettle and allows him to exercise his judgment to an extent that he takes a more personal interest in his work. No other occupation employing many men is so strenuous and dangerous as that of the American miner. The statistics showing the mortality among them are seldom if ever complete, owing to the difficulty of determining the mortality directly attributable to the occupation. Miners consumption and pneumonia cause far more deaths than falls of rock and 'negligence' notwithstanding the fact that the Mine Inspector's report and the verdict of the coroner's jury show that the latter is about the only cause of a miner's decease.

Miners and Strikes

Much has been said derogatory to the miner in connection with the strikes of the past twenty years. It is not the intention here to attempt to justify those deplorable occurrences which have resulted in the loss of life or property. They are indefensible and should have been prevented, as they could have been had there been a proper understanding between manager and miner. It is my contention that the fault has been almost entirely with the management of those operations where trouble has occurred. A superintendent is supposed to be an intelligent, educated, and experienced man, and it does seem as though such a one should not have allowed such small differences as those which led to some strikes to be the ultimate cause of such large loss of life and property. To those who contend that such demands as have been made for increased pay were unreasonable, the miner points to the figures of those who have closely studied costs and says, "increased pay means increased efficiency." To those who say they object to dictation, the miner calls attention to conditions at Butte, the home of the union, and where the dictation of the miner in its broadest sense is recognized by the management and asks, "What questions have ever arisen there that have not been speedily settled to the mutual satisfaction of all parties concerned?" To those who argue that much of the underground labor is unskilled, the miner replies that the duties of these unskilled laborers are extremely arduous. In all of these arguments the miner has a powerful ally in the size of the graveyard on 'the flat'.

Those of us who understand the miner have learned to appreciate him though recognizing his faults. He is a generous, resourceful, and skillful fellow, who, when his work is carefully watched and he is kept 'broke', will turn out work, under disagreeable conditions, in a manner that is truly surprising. Fortunate is the shift-boss who has a crew of experienced miners, for then his work is so simplified that even a 'school of mines man' could almost do it. Fortunate is the foreman of such a crew, for he shall be warmly congratulated by the 'super'; and fortunate is the superintendent, for at the end of the year as he casts up results he will say, "Well done, good and faithful servants. On the results of this year's work shall the Board of Directors be induced to raise my salary."

Costa Rica, according to official statistics, exported $1,190,406 worth of gold and silver during 1911. This was an increase of $379,220 over the previous year. The principal producers were the Abangarez Gold Fields of Costa Rica and La Union Mining Co. Large shipments have been made by other mines, and this branch of Costa Rica's industrial development is progressing steadily. The hydro-electric plant of the Abangarez company was in course of construction during 1911 and was completed in March 1912. This plant, constructed by an American firm, makes 2000 hp. available, and will materially extend and cheapen the operations of the Abangarez company. La Union Mining Co. has been crushing steadily and has increased its cyanide plant. The export of gold and silver during each of the past five years is as follows (nearly all shipped to the United States): 1907, $520,056; 1908, $673,188; 1909, $792,847; 1910, $811,186; 1911, $1,190,406.

Rich placer deposits are being worked about 100 miles from Sansing, in central Manchuria, at Hua-pi-kou, Tai-ping-kou, Tiao-tze-kou, and Hei-pei-kou. Native methods are employed, and only the coarse gold is saved. About 400 people are employed.

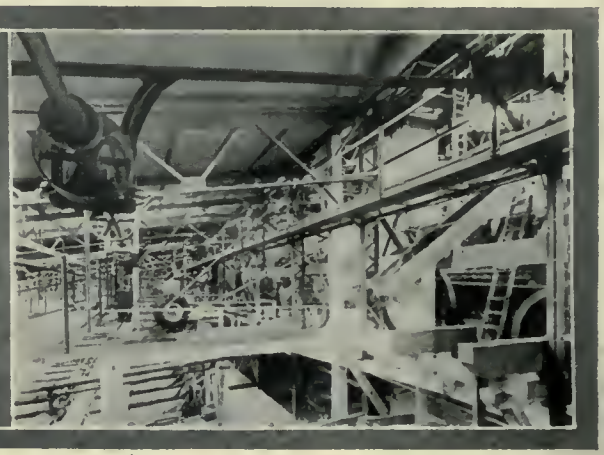
Electrical Equipment at the Ohio Mill

By An Occasional Contributor

The new unit of the Lark mill of the Ohio Copper Co. will bring the total capacity up to 3000 tons per day. The selection of motors in the new unit was given more careful consideration than is usual in milling plants. The idea was to have as many motors duplicates of one another as possible and still choose motors fitted in type and capacity to stead of at its maximum load. This fits ore-crushing service much better than the ordinary type of motor. Among the other equipment are four 50-hp. type 'CCL' motors, two of which drive a set of Gates rolls each. The other two drive elevators and trommels. Two 100-hp. motors of the same type each drive two Gates rolls. Eight 75-hp. motors each drive a 6-ft. Chilean mill. One of these is shown in the illustration.

This completes the crushing end of the mill. All motors are supplied with standard auto-starters,

MOTOR FOR CRUSHER AND ROLLS.



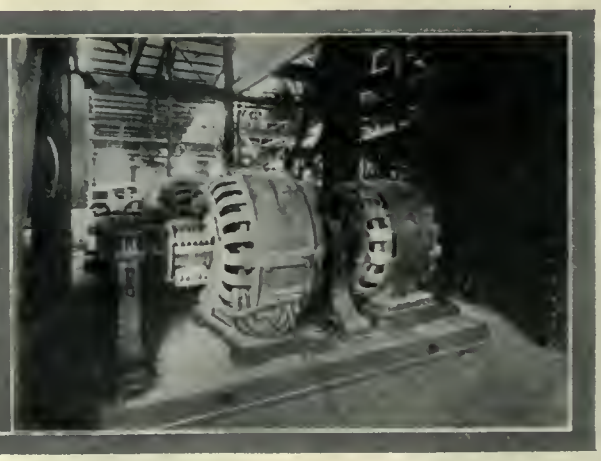
MOTOR DRIVE OF CHILEAN MILLS.

the duty to be performed. Power for the mill is obtained from the Telluride Power Co.'s system and is stepped down from approximately 44,000 volts to 460 volts by three 500-kva. water-cooled transformers.

On entering the mill the ore is passed through two Blake jaw crushers. These are driven from a

equipped with no-voltage releases and automatic overload relays, so that either in case of overload or failure of power the handles used to operate the auto-starters are automatically returned to the starting position. It is therefore impossible for any of these motors to be damaged by the power going off suddenly and then suddenly coming on again. The

ALDRICH PUMP MOTORS.



MOTOR-GENERATOR SET.

special 100-hp. mill-type motor known as the Westinghouse type 'MS'. This motor, which is of heavy, rugged, mechanical design, is similar to the motors used in steel-mill service, and is shown in one of the illustrations, in the immediate foreground on the right-hand side. In addition to its heavy construction, the motor has a high maximum torque compared to its rating; in fact, it will pull about 250 hp. momentarily. It is designed with a flat efficiency curve, with the highest efficiency at 100 hp., so that it will have good efficiency over its entire range, and its best efficiency at its average in-

overload relays have a time element dash, so that momentary overloads within the capacity of the motor will not throw the circuit off. This is, of course, particularly desirable on crushing machinery. The Wilfley and Deister concentrating tables are driven by belting from small 20-hp. General Electric standard motors.

A pumping plant in connection with the mill is supplied with power from three 100-kva. Westinghouse transformers similar to those used for supplying power to the mill, except as to capacity. The pumping plant consists of three triplex Aldrich

plunger-pumps, gear-driven by a 100-hp. type 'CCL' motor. This plant is shown in the illustration. Ore is brought to the mill over an electric railway running through the famous Mascot adit. This is operated with General Electric locomotives, and power is supplied by two Westinghouse motor-generator sets, each consisting of a 225-hp. motor driving a 150-kw., 600-volt generator. These are shown in the illustration. The generators are interpole and operate at 1150 r.p.m. They are situated in the mill and are subject to much dust, but nevertheless have been handling the very variable load due to the railway, and including overloads as high as 200%, without any sign of distress.

Base Metal Production of Colorado

By P. H. Argall

The Arkansas Valley smelting plant at Leadville has four furnaces operating at full capacity, treating an average of 600 tons per day. The only mechanical improvement of note has been the installation of two 100-ton Dwight-Lloyd sintering machines which operate successfully. The ore supply has been more abundant than in any year since 1907, and huge stock piles have been built up in the yards awaiting treatment. There is now enough ore coming into the plant to supply five furnaces, but the fifth has not been blown in owing to the fact that there is an appreciable shortage of labor which prevents any increase at this time. Owing to the sailing of a large number of Greeks, Bulgarians, and southern European natives of belligerent tendencies, there is a scarcity in the labor market.

The Ohio & Colorado smelter at Salida had in 1912 the most successful year in its history. The plant is now treating 400 tons of ore per day. The chief mechanical change consists in the substitution of electricity for steam power, the plant having been electrified throughout. The large zinc separating and concentrating plant of the American Zinc Extraction Co. at Leadville, closed down early in 1910, has lately been purchased by the interests of the Sutton, Steele & Steele Dry Concentrating Co. It is rumored that the new owners will remodel the plant and make it available for treating low-grade mixed sulphides of the Leadville district.

Leadville has produced its usual quota of mixed sulphide ores during the past year, shipping them to the mills at Canon City and the Western Chemical Co. at Denver for treatment. Owing to the increased production of zinc carbonate, the zinc output of Leadville has been the greatest in many a year. The zinc smelters now take oxidized ores containing as low as 18% zinc, and large shipments of this material have gone forward. At Redcliffe the Eagle River Mining & Milling Co. has developed an immense shoot of low-grade sphalerite ore in Battle mountain. This ore is being treated at the rate of 100 tons per day at a magnetic mill in Eagle river canyon, which turns out about 30 tons per day of 45% zinc concentrate.

The Pueblo smelter operated at nearly full capacity throughout the year, but was somewhat hampered by lack of suitable silicious ores to offset the increasing receipts of concentrate. The Colorado Fuel & Iron Co. steel works at Pueblo had a very successful year, the output being valued at $15,000,000, as against $13,700,000 for 1911. The following table, compiled by the *Rocky Mountain News* from the various mill and smelter reports, gives an idea of the metal output of the chief lead and spelter producers of Colorado.

In total operations, including ores from British Columbia, Ontario, Arizona, Idaho, Montana, New Mexico, South Dakota, Utah, Wyoming, as well as the Colorado mines, the ore-treatment plants included in the metallurgy of Colorado gained $13,698,691 over the total returned for 1911.

	Gold.	Silver.	Lead.	Copper.	Spelter.	Total.

*United States Zinc plant at Pueblo produced $48,138 in zinc dust used at the cyanide mills.

Goldfields of considerable promise have been discovered not far from Tanga in German East Africa, according to *Koloniale Korrespondenz*. These are the first gold deposits as yet discovered in the immediate neighborhood of the coast, but in the interior of German East Africa the occurrence of gold has been proved in several places by more or less thorough development work. Two gold properties are now exploited with fairly remunerative results, one at Sekenke, on the western border of the Isamba Downs, about 475 miles inland, and the other at Nyasamo, east of Mpanza, near Lake Victoria. At the former property gold has been recovered with constantly growing profits since 1900, the gold contents of the quartz averaging about 1.6 oz. per ton. At the end of 1910 a 10-stamp mill was erected, and since has been uninterruptedly working. At present twenty Europeans and 700 native 'boys' are employed on the property. At Nyasamo a 5-stamp mill has been crushing at the rate of 10 tons per day since 1910. The ore reserves of the property are said to be ample, and the gold content satisfactory. The gold exports from German East Africa totaled, in 1909, $60,000; in 1910, $215,000; in 1911, $260,000. The gold production of the two mines is somewhat higher. The ore reduction methods are similar to those used in the Transvaal.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

The State Mineralogist

The Editor:

Sir—Believing that for the good of the State Mining Bureau your readers will be interested in learning, as we have done, both sides of the controversy which resulted in the removal of W. H. Storms from the office of State Mineralogist, we have obtained, and are asking you to publish with this letter, the report of the State Board of Control dated July 25, 1912, but issued last month, and the statement of the Board of Trustees of the State Mining Bureau made January 17, immediately after the receipt of the Board of Control's printed report.

Referring to the first-named document, we are convinced of the truth of the statement contained therein, "that the annual appropriation of $20,000, set aside for the support of the bureau, brings very little return either to the mining industry or to the state at large." A perusal of both documents shows that this condition on July 25, 1912, was not properly chargeable to Mr. Storms, but to the legacy of loose methods and political favoritism left him by his predecessors. The Trustees' report of January 17 shows that Mr. Storms was doing his best to correct the system of abuses, and it seems probable that if he had been content to permit the continuance of the previous loose methods, the controversy would not have arisen and Mr. Storms would still be the State Mineralogist.

There was a time in the bureau's history when it was of real benefit to the mining industry of California, and we, in common with many others interested in that industry, have obtained information of value from its records and publications. But for many years it has been a political football, and it was this condition that we hoped to see remedied by the appointment of Mr. Storms, whose candidacy for the position we supported. We believe that if he had been given time and friendly, instead of unfriendly, criticism he would have brought about the necessary reforms in the Mining Bureau; but as support from the state administration was withheld, we believe he acted for the best interests of the bureau in giving up the fight to retain his position.

Referring briefly to the accusations of the State Board of Control, we find a statement that the funds of the bureau "have been handled in a loose manner." This charge has been quite fully discussed in the report of the Board of Trustees, which board, by the way, is responsible for the handling of funds. The State Mineralogist is not responsible for the handling of these funds. It is interesting to note, in the general report of the State Board of Control, that a page is devoted to the discussion of 'revolving funds' which are allowed 24 state institutions. There seems to be no logical reason for denying a similar fund to the State Mining Bureau. It is stated by Mr. Storms, and we believe it to be true, that not one cent of salary was ever paid to any employee in advance; and that the sums advanced were for legitimate contingent expenses, such as are provided for in the revolving funds of other state institutions.

The accusations regarding the donation of bureau publications to various institutions and persons, the alleged failure to catalog the contents of the museum, and the circumstances of Mr. Prutzman's employment by a previous board and retention by the present one, have been fully covered by the letter of January 17. This brings us to the charge that "Mr. Storms was frequently absent on trips to different sections of the state." On this point we conceive it to be one of the most important functions of a properly constituted mining bureau to collect and disseminate information regarding the mining resources of the state, and with this object in view, it is not only entirely proper for the State Mineralogist to spend a portion of his time visiting the mining regions, but it is absolutely necessary that he do so, if the bureau is to be properly conducted. He should not examine privately owned mining property for a fee, and it is not charged that Mr. Storms has done so; but, as most mining property in the state is privately owned, he cannot collect information without visiting mines so owned. Unfortunately, the financial limitations of the bureau prevent the maintenance of an organization for a systematic study of the state's resources, and it is therefore possible that little public good resulted from some of Mr. Storms' trips; but in one instance which we have in mind, we believe that his visit to a mining district with the timely publication of his conclusions regarding it, saved many times the year's cost of the Mining Bureau to the people of this and other states, and added materially to the honor of California as a field for legitimate mining investment.

In another instance Mr. Storms was in Bakersfield in consultation with the oil men regarding the water situation in the Midway field. This work was eminently practical and desirable, and was of more benefit to the state than any mere routine office work.

In conclusion, we wish to express our confidence in the honesty and integrity of Mr. Storms and in his ability as a mining engineer.

San Francisco, January 24.

REPORT OF THE BOARD OF CONTROL

July 25, 1912.

His Excellency, Hiram W. Johnson,
Governor of California.

Sir—Through its accounting department the State Board of Control has completed an audit of the accounts and an examination of the affairs of the State Mining Bureau. At this time it is deemed proper to call your attention to certain matters and practices disclosed by the examination.

A general survey of the work of the State Mining Bureau

as conducted at present convinces the State Board of Control that the annual appropriation of $20,000, set aside for the support of the bureau, brings very little return either to the mining industry or to the State at large. It is also apparent from an examination of conditions at the bureau that radical changes in its conduct are necessary to bring about any beneficial results. The funds of the bureau have been handled in a very loose manner and without regard to legal restrictions; the aims to accomplish which the bureau was created have been lost sight of; employees who under an aggressive management could devote their time to accomplishing work of value to the mining industry, are busy only a small part of each day; and the result is that nothing of value is accomplished.

The manner in which the funds of the bureau have been handled can best be illustrated by the fact that when C. L. Avery, superintendent of accounts for the State Board of Control, arrived at the Mining Bureau to begin his audit he found cash on hand and in the bank amounting to $539.36, whereas there should have been $2,982.10. This discrepancy was represented by memoranda and tags recording loans and advances to the State Mineralogist and employees, payment of salaries and other expenses, none of which, with the possible exception of one, could be legally paid out of these funds. These funds on hand at the Mining Bureau represent, (1) the publication fund, which is made up of receipts from the sale of publications of the bureau, and this fund cannot be legally used for any other purpose than defraying the expense of printing and publishing publications; (2) a so-called 'revolving fund,' which has accumulated in the course of years, and should long ago have been deposited in the state treasury, as it was made up in large part of overcharges on payrolls, etc.; (3) a library fund of a small amount received from the sale of books from the library of the bureau, which also should have been deposited in the state treasury. These funds have no relation to the annual appropriation of $20,000 for the support of the bureau. These three funds were held in one account in a San Francisco bank. They were all checked upon for advances on salaries, loans, payment of salaries and other purposes. One of the tags, signed by W. W. Thayer, the bookkeeper and cashier of the bureau, was more than a year old. It was for the sum of $50 and was advanced ostensibly for the payment of freight on shipments of specimens to the bureau. No freight was paid out of it, and Mr. Thayer was required to return the $50 to the fund. Mr. Thayer also had other memoranda of advances to himself in the cash drawer.

Cash tags in the sum of $490.75 were deposited in the cash drawer in the name of Paul W. Prutzman, a mining engineer, who was supposed to be giving his entire time to the preparation of a bulletin on the oil industry of California. Mr. Prutzman's employment on this oil bulletin began during the incumbency of L. E. Aubury as State Mineralogist but has continued for seven months during the incumbency of W. H. Storms, the present State Mineralogist. Up to the present time there has been no result of this employment shown. The employment of Mr. Prutzman is of interest for several reasons. In the first place, the employment of Mr. Prutzman was illegal, because of the fact that there were no funds from which he could be legally paid; secondly, it had come to the knowledge of the State Board of Control that Mr. Prutzman, during the time that he has been drawing a salary and traveling expenses from the State Mining Bureau, and while he was supposed to be engaged in gathering data for an oil bulletin, was in the employ of another department of the state government for three months and collected fees for services rendered which took a large part of his time—this employment undoubtedly accounts for the fact that the oil bulletin has been long delayed; thirdly, the payment of Prutzman's salary and expenses out of the funds on hand was illegal, for the reason that two of the funds should have been deposited in the state treasury long ago, and the other could only be used legally to defray the cost of printing pamphlets and other publications. Mr. Storms showed little knowledge of what time Mr. Prutzman has devoted to the service of the Mining Bureau. The preparation of the bulletin has dragged along, Mr. Prutzman apparently being the sole person to determine what time he should give to the Mining Bureau for the salary and expenses paid. For the reasons above set forth, the State Board of Control has notified the State Mining Bureau that it will audit no further demands for salary or expenses for Mr. Prutzman.

Cash tags for various small amounts, signed by H. F. Williams, janitor, were carried against the funds for several months, but were taken up at the direction of Mr. Avery. Cash tags signed by Mr. Storms were also found in the cash drawer. They were not offset by any expense vouchers. Mr. Storms has been notified to take these up. The records of the bureau for traveling expenses show that Mr. Storms was frequently absent on trips to different sections of the State. Several of these trips, Mr. Storms explained, were made to visit mining properties owned by individuals on which he rendered expert opinions. It is plain that if the State were to maintain a department and pay the expenses for the investigation of mining properties for individuals, the demands would be such that many thousands of dollars would have to be appropriated annually for this one purpose. The absence of the State Mineralogist on these trips unquestionably accounts for the lack of aggressive action in the bureau.

As a department of the Mining Bureau, a museum is maintained in which have been collected thousands of specimens of valuable ores and minerals, together with a collection of relics of early mining days. This property is valued at many thousands of dollars. There is no record or catalog of the contents of this museum and no attempt has been made, either by Mr. Aubury or Mr. Storms, to take an inventory of this valuable property. The necessity of such a record is apparent from statements made by Mr. Storms to the effect that persons who had donated valuable specimens to the museum have complained that the gifts are not there. Because of the lack of records, there is no way to trace these missing articles. P. K. Swain and C. C. Selbie were successively employed as curator of the museum, but it is extremely difficult to ascertain what they accomplished in this position. Neither one made any attempt to catalog the exhibit.

Another department of the bureau in which matters have been handled in a loose fashion is that of the publications. Provision is made by law for the publication of pamphlets and bulletins which will be of value to the mining industry, and in order to provide funds the statute creating the State Mining Bureau requires that these publications shall be sold at the actual cost of printing them. By this means a revolving fund is established. A practice arose under the administration of Mr. Aubury, and has been continued under Mr. Storms, of giving away free of charge these publications to certain individuals and making charges for them to others. Many copies have been distributed to other mining bureaus and departments in exchange for similar works. To this there can be but little objection, but in many other cases these publications have been given to friends or acquaintances of the State Mineralogist, while the general public is required to pay.

In extenuation of the fact that many illegal charges were recorded against the funds of the bureau, Mr. Storms complained that the $20,000 annual appropriation was inadequate to the needs of the bureau. This board, however, respectfully advises your Excellency that the fault lies not in the amount of money appropriated, but in the manner in which it is expended.

The sole results of the activities of the Mining Bureau, so far as this board can learn, have been: the dissemination of some incomplete statistics, the making of determinations by the chemist employed, and the preparations of an oil bulletin by Mr. Prutzman, which has been heretofore referred to. If these are the objects of the maintenance of the State Mining Bureau, they can be attained in much more economical fashion. Complete and accurate statistics can be secured from the Federal Mining Bureau on request, the determining characters of ores is only sufficient

to keep one man busy, and it is apparent from the manner in which Mr. Prutzman has handled the assignment that the compilation of an oil bulletin does not require very close application. If these were the only objects to be attained, they could be accomplished for approximately $4000 or $5000, and there would be no need of maintaining a big establishment. As it is, the payroll alone of the State Mining Bureau is $15,540 per year, and the employees are only busy for a fraction of each day. It is apparent that there is no definite work outlined, and the employees simply put in time each day. The wide field of stimulating the mining, oil, and building material industries of the State receives only perfunctory attention. This work could be carried on with big results by an elimination of certain positions in the bureau, the reassignment of the work among the remaining employees, and the devotion of the salary money saved to a proper study and exploration of the particular resources of the State which fall within the jurisdiction of the bureau. The carrying out of these suggestions would tend to reduce the overhead cost in the office of the bureau to a reasonable basis and afford means of putting men in the field to prosecute the work of gathering accurate information, data and statistics. Absolutely no attention is being paid to this feature of the work at the present time outside of the employment of Mr. Prutzman.

Mr. Storms' complaint of the lack of funds is not strengthened by the record, which shows that the salary of Mr. Thayer was increased in June by $25 per month; the salary of the janitor was also increased; legal charges for publication were waived; Mr. Storms has felt that there were sufficient funds to warrant him in traveling from which the State received no benefit; Mr. Prutzman has been paid a monthly salary and expenses while devoting his time to other work.

Many of the practices which still obtain have gone on in the department for years, and the records show that the bureau has gradually been settling into a rut in which it is of little or no use to the State. This board has notified the Mining Bureau that the funds which have been illegally used in the past must be forthwith deposited in the state treasury, and that in the future all claims and expenditures will have to be made in accordance with the law and the regulations governing all departments of the state government. This board feels that such action will result in a proper restriction of expenditures, but that the matter of increasing the efficiency of the department is one which should engage the attention of your Excellency.

This report is respectfully submitted this 26th day of July, 1912.

JOHN FRANCIS NEYLAN,
Chairman State Board of Control.

REPORT OF BOARD OF TRUSTEES

January 17, 1913.

Hon. Hiram W. Johnson,
Governor of California.

Sir—We are in receipt of a copy of the first biennial report of the State Board of Control, in which we find a communication to your Excellency dated July 25, 1912, which contains various severe strictures upon the management of the State Mining Bureau. In another part of the work we find the following:

"Heretofore in this report reference has been made to the work which was necessary to eliminate graft, extravagance and wasteful methods in those state institutions and departments where these evils existed."

Then follows the name of the State Mining Bureau, among other institutions. There is nothing in this communication of July 25 making any direct accusation of any misappropriation of funds, or of graft, in the management of the affairs of the bureau, but the whole report taken together would have a tendency to create in the mind of a casual reader the impression that such accusations and charges had been made. This report to you is dated July 25, 1912, but as it is contained in a report bearing a much later date and which is published to the world on the first day of January 1913 it seems to speak as of the time of the publication of the report and consequently brings its criticisms and reflections down to date. With these considerations in mind, namely, that a false impression may not be created of the work of the Bureau, and as to the fidelity and integrity of its management, and that the facts may be presented as they exist today, we wish respectfully to make this statement to you so that the position of the bureau may be a matter of record as well as these charges against it.

At the outset we wish to say that it seems a remarkable thing to us that a letter dated July 25, 1912, should be published in a report issued on the first day of January 1913, when many of the matters contained in that letter have been the subject of official communcation and harmonious arrangement between the Board of Control and this Bureau since the date of that letter, especially with reference to the subject of payments out of funds in the hands of the bureau prior to the allowance of claims by the Board of Control and the receipt of the money from the State Treasurer's office. This was a custom of years standing, and while perhaps technically open to argument, seemed to be almost a matter of necessity if the work of the bureau was to be conducted. This was the subject of communication in a letter from the State Board of Control to our Bureau dated September 25, 1912, which we believe was the first official notification that we had that there was any objection to this practice, and in our reply to that, dated October 11, 1912, we advised the Board of Control that "though it may result in the crippling of the bureau and in the serious limitation of its work, we have to advise that the practice will be discontinued." Since the date of this communication no moneys have been paid out except as the same have been received from the State Treasurer on vouchers properly allowed by our bureau and the State Board of Control. The practice grew up under old administrations because it seemed for the best interest of the bureau. The State Board of Control, in discharge of its duties, called attention to its alleged illegality, and this bureau, having thus had the matter called to its attention, at once undertook to conform our system of handling our funds to the requirements of the Board of Control except as to the use by us of our donation fund, which we consider subject to our own control. We take it that the function of the Board of Control is to see that the law is observed and to correct abuses, and if it is aided in this regard by a cheerful acquiescence on the part of other boards and officers, we do not see why past acts which have been the result of custom, should be the subject of animadversion, criticism and even accusation.

Answering the seventh paragraph of the report, it states "that a tag signed by W. W. Thayer, the bookkeeper of the bureau, was more than a year old, that it was for the sum of $50 and was advanced ostensibly for the payment of freight on shipments of specimens to the bureau, and that no freight was paid out of it, and Mr. Thayer was required to return the $50 to the fund." This is a practical accusation of a diversion of State funds, and if it has that intention, it is untrue. It is true that Mr. Thayer did receive from the funds of the State Mining Bureau $50 and that the $50 was represented by his voucher therefor. The reason for his receiving this was that there had been in process of construction, in the quarters of the bureau, an exhibit of the structural materials produced in the State of California, to which exhibit Mr. Thayer devoted a good deal of time. All of the materials composing this exhibit were donated by the producers of the material. From time to time as these materials would arrive, draymen would come to the bureau building with the material, and the draymen had to be paid, or we could not receive the material for the exhibit. Realizing the awkwardness of this position, created largely by the fact that the State does not give us advance funds to use, this $50 was taken out of our donation fund, which has been in the bureau for over fifteen years. It is true that Mr. Thayer replaced this $50, but the replacement came from moneys sent to the bureau by donators of this building material, who in addition to

donating the material, had agreed to pay all freight and drayage charges as well as the cost of installation. This money was not used by Mr. Thayer for his personal use and was not returned from his personal funds.

It is alleged that loans were made from our funds to the State Mineralogist and employees, which is not a correct statement of facts. In no instance was money ever advanced except for uses of the bureau, and these were always made up by allowances by the Board of Control. The advances to the janitor, H. F. Williams, of which the Board of Control makes so much, at no time exceeded $2, and were advanced for carfare while running errands for the Mining Bureau.

In one respect this report seems peculiarly unjust to the present administration, because if an illegal employment was entered into, it was during a former administration of the bureau, and the present administration, unless it were to lose the fruits of the money already expended, was compelled to continue the work. We refer to the employment of Mr. Prutzman in the preparation of an oil bulletin. We fail to see, however, how his employment can be said to have been illegal. He was regularly employed at a monthly salary and engaged in scientific work for which the bureau was created. The question of the results obtained by his employment is not here involved. The proof that his employment, as a matter of fact, was not regarded as illegal by the Board of Control is evidenced by the fact that demands approved by the trustees of this bureau for Mr. Prutzman's salary for the months of May, June, July 1911, and February, March, April, May, June 1912, were approved and paid by the Board of Control. Furthermore, the Board of Control now has in its hands additional demands which it has not passed upon, and we have no record of any objection to these claims except some dispute as to the amount of time Mr. Prutzman was employed in the service of the Fish and Game Commission. In this report of July 25 it is stated that he was employed for some three months of time. This bureau knew of employment aggregating four days, and a deduction was made for that length of time. In our letter of October 11, 1912, to the State Board of Control we advised that we would take the matter up with the Fish and Game Commission, which was done. Mr. Prutzman subsequently went over his books and under a liberal allowance against himself figured out that he had been employed five days and one-half hour by the Fish and Game Commission, and that body was able to give us no different figures. We have repeatedly written the Board of Control asking for action upon this claim, and on December 14, 1912, we have a letter from this board stating that the matter would be taken up speedily now that the preparation of the budget was off their hands. Thus we see that while the Board of Control in its report of July 25 claims that Mr. Prutzman's employment was illegal, it has audited his demands and now has before it additional demands which are only disputed because of the uncertainty of his employment by the Fish and Game Commission. Does it seem quite fair that this should be included in the biennial report of the Board of Control in view of its own action subsequent to the date of its report?

In regard to the charge that the employees of the bureau merely mark time, we call your attention to the letter of the Board of Control to our bureau of September 25, 1912, in which it states that "it is known that the stenographer and at least one other employee of the bureau have a great deal of leisure time", so you can see that at this time the charge was limited to these two employees alone. In our letter of October 11, 1912, in answer to this, we wrote as follows:

"We have carefully gone over the list of our employees and have not been able to see how any member of the force could be dispensed with or how the duties which are assigned to the different members could be advantageously performed by other members." * * * "The members of the Board of Trustees of the State Mining Bureau devote as much time as possible to the supervision of its affairs, as is well known, without compensation, but as you are fully aware our sole desire is to get the best possible results from the expenditure of the State funds. If you have any information showing that our employees are not rendering value for their salaries, it will be of great assistance to us, and we would greatly appreciate it, if you would give us the benefit of this information." To this we never received any reply. Comment on this seems scarcely necessary. If the Board of Control had any such information, was not our bureau entitled to it? If the board had been actuated by the spirit of helpfulness, which all public officials should have, were we not entitled rather to friendly aid and suggestion than to hostile criticism in a public report which becomes a permanent record in the State archives?

The quarters of this bureau are always open on business days from 9 A.M. to 5 P.M., and all our employees are constantly busy. The bureau is used very extensively by the citizens of the State. We have a voluminous correspondence to attend to, and to accomplish the work assigned us by law keeps our present employees busy. The service rendered seems to meet the demands of the people and to fulfil one of the functions for which the bureau was created.

In regard to the trips which Mr. Storms, State Mineralogist, has taken for the examination of properties, in every instance, except one, these trips were previously authorized by this board. We have always endeavored to confine this work of the bureau to matters of general interest, but necessarily an examination of mining districts sometimes involves the examination of private property.

It is charged "that there is no catalogue or inventory of the museum and no attempt has been made by Mr. Aubury, former State Mineralogist, or Mr. Storms, to take an inventory of this valuable property." This is incorrect, for there is a catalogue of the museum in five volumes, and such catalogue has been exhibited to the chairman of the Board of Control. It is true that there is no inventory of this museum, any mining man knows that an inventory of a museum consisting of mineral specimens cannot be made, as there is no fixed market price for mineral specimens. The State is fully protected by the existence of the catalogue. This catalogue is kept up from day to day by the present curator of the museum, and each specimen is numbered and labeled to date. It is charged that the bureau gives away its publications when the same should have been sold. It is true to this extent, that this bureau has given copies of its publications to other institutions in exchange, and to prominent mining publications and newspapers; but the Board has always considered that while it has not received actual cash for these books, it has received many times their value by the publicity given by these journals to the mineral resources of the State, based upon information derived from these publications. Some copies have been furnished, free of charge, to public libraries, universities and schools of the State, but this bureau has not given away any publications to any person not giving to this bureau full value therefor.

The conclusions reached by the Board of Control as to the result of the activities of the Mining Bureau are so much a matter of opinion that it is difficult to answer this. We beg to say, however, that judging from the reception which the work of the bureau has always received, there is apparent uniform appreciation on the part of the public which would naturally be interested. Our bulletins and publications are eagerly sought for, and many, on account of the demand, are now out of print. The oil bulletin prepared by Mr. Prutzman, which is particularly mentioned, since the date of this report, as the Board of Control is fully aware, is now in type, and the last proofs are now in our hands for correction. It will make a publication of about 400 pages, and we have every reason to believe that it will be of great value to the State and a credit to the Mining Bureau. A very cursory examination of the bureau will show that there is a very small surplus left for general outside work after the regular expenses of maintenance are provided for.

Beginning with the month of July of 1912, a reduction was effected in the regular expenses of maintenance by dispensing with the services of two employees for whom there

was found to be no immediate use, thus making a monthly saving netting $175. Beyond this we have not found it possible to reduce the regular expenses of the bureau without crippling its efficiency. For some months we have not been engaged in any outside work, as we had hoped to undertake the preparation of a report on the iron deposits of the State. We now have on hand an accumulation approximating $2250 which we propose to use for this purpose. Finally, as to the work of the bureau, we wish to add that we have always sought to expend the State's money for the purpose for which it was appropriated. We believe that the existence of the bureau has been justified by the work which it has accomplished and that the great State of California would not be satisfied to rely upon the Federal Mining Bureau or other sources for information which it should furnish to its own people.

In conclusion, we would say that this report of July 25, first known to us through publications in the daily press in January 1913, was the more surprising to us as we have to bear testimony to a past uniformly courteous and considerate treatment by the Board of Control, as all of our relations, in the past, have been apparently most cordial. The differences of opinion between the two boards have been discussed most impartially and with entire good feeling on both sides. Where legal questions have been involved, we have always expressed a willingness to leave the matter to the authorized legal advisor of the State Boards, and on the other hand the Board of Control has urged its views with an unexceptionable fairness. As to the feeling of the board toward this bureau, we have its own assurances, for on October 18, 1912, in a communication to us, the State Board of Control, over Mr. Neylan's own signature, states, "In conclusion, we beg to assure you that the Board of Control has not indulged and does not now indulge in any criticism of the members of your board, knowing that you gentlemen have had the sole desire of obtaining the best results possible for the State." With this presentation of the facts and with this expression of opinion by Mr. Neylan, the writer of the report of July 25, this board is content to go on record.

We believe in justice to the State Mineralogist and the employees of the bureau, that this answer should be transmitted to the Senate and Assembly of California.

Respectfully yours,

A. H. Ward, President;
Henry E. Monroe, Secretary;
E. C. Hutchinson,
Calvert Wilson,

Sorting Out Waste

At the Schoenherr-Walton mine, Webb City, Missouri, it has been found profitable to pick out the waste rock before it goes through the crusher. After being hoisted the ore is dumped into a hopper and passes over a grizzly. Here the first picking is done, this being the common practice in all the mills of the district. After leaving the hopper, however, the ore is again picked before it goes to the shaking-screen, through which the undersize passes to the crusher. At first a wheelbarrow was used to remove the waste, then a tramway over which was operated a car, but as the quantity of the waste taken from the screen exceeded expectations, it was deemed advisable to construct an extra hopper into which the waste material is thrown direct from the screen. From the hopper it is removed by an inclined tramway that leads to the waste pile. Two men are employed in picking out waste. Each saves on an average of 25 tons of barren rock daily from going through the mill. The wage of each is $2.25 per day. The cost-sheets of different mines for running a ton of ore through the mill after leaving the hopper vary, but 24c. per ton may be said to be a fair average. The saving in dollars and cents is comparatively small, being slightly under $4 for each workman, but considering the wear and tear on machinery, and the fact that the finer ore is milled much more rapidly than would be the case where larger particles are permitted to enter, the saving is much greater.

LONDON

Dressing of Tin Ores.—New Methods.

Some of the meetings of the Institution of Mining and Metallurgy have an unfortunate tendency to be dull and unprofitable. This is usually the case when a carefully prepared paper in the form of a treatise is presented by a past master. For instance, A. J. Clark and W. J. Sharwood's valuable record of metallurgy at the Homestake suffered from neglect in this way a month ago. As a contrast, the paper presented by W. Fischer Wilkinson this month was as a spark to tinder. A vast crowd was there and tongues were generously unloosened. The title of the paper was, 'On the Dressing of Tin Ores in Cornwall.' During his two years tenancy of the principalship of the Camborne Mining School, Mr. Wilkinson learned a good deal himself. His previous chief work, as a member of the engineering staff of the Consolidated Gold Fields of South Africa, naturally did not afford him much scope for obtaining experience in the dressing of tin ores. His paper showed signs of gaps in his acquaintance with his subject, and included a large amount of matter which makes the reader exclaim, *Connu!* For instance, his disquisition on the faults of the vanning-shovel and on the necessity of making a real chemical test of tin ores, reminded his hearers of the proverbial killing of the dead dog; and in his bibliography on this department of his subject he failed to make mention of the famous article by Richard Pearce, which is in fact the classic. However, the whole of the paper was not valueless, for a useful service was done to metallurgical practice when Mr. Wilkinson commenced to study extraction and classification. The most vital item in the paper was the result obtained by coarse crushing. Mr. Wilkinson crushed with stamps having a 4-mesh screen, and obtained as a first concentrate on a Buss table 42% of the cassiterite in the ore, in a concentrate assaying 32% metal. The screen employed was made of wire of less diameter than the width of the hole, and the aperture was probably $^3/_{16}$ in. The Buss table acted as a classifier as well as a concentrator, and it was possible to obtain three other products. His scheme for subsequent treatment involved sizing, classifying, and re-grinding, and one of the ultimate products, part of the coarse sand, could be rejected as too poor to re-treat. Owing to limited resources in the way of plant, he was unable to obtain satisfactory results, but the experiments should eventually lead to something useful. It has commonly been supposed that Cornish ores require fine grinding because the particles of cassiterite are fine, and Mr. Wilkinson's recovery with so coarse a mesh is notable. Other mine managers in Cornwall have discovered that past practice is not infallible, and notable among them is Josiah Paull, of South Crofty, who uses 14-mesh. At the Geevor mine, stage-crushing with Hardinge mills instead of stamps is being tried, and the results are most promising. Details will be forthcoming for publication before long.

CRIPPLE CREEK, COLORADO

Milling of Ores.—The Clancy Process.

Of the 530,000 tons of ore shipped out of the Cripple Creek district last year, approximately 70% was treated at the Golden Cycle mill at Colorado City, 20% at the Portland mill, and 10% by the smelters. The open rates under which ore is now shipped to these mills are as follows: Under ½ oz., $4 per ton; ½ to ¾ oz., $5; ¾ to 1 oz., $6; 1 to 1¼ oz., $6.25; smelter, 1¼ to 1½ oz., $6.50; 1½ to 2 oz., $7; 2 oz. and over, $8. On account of a surplus of concentrate the smelter grade ore begins at 1.25 oz., and a considerable tonnage of ore of this grade, or a little better, was smelted. In the district the method of treatment worked out originally at Stratton's Independence, Ltd., has become the standard of practice, the new Port-

land mill having accepted the last step, reconcentration, during the past year. No more is heard of secret processes or patent nostrums, and steady work is the order of the day. The new Portland mill treated 170,000 tons of ore during the year, and Stratton's Independence treated 117,500 tons, all material regarded as worthless a few years ago and averaging about $3.10 per ton.

The big excitement promised for last year, the Clancy process, has nothing to report. Owing to poor construction, the crushing plant had to be torn down and rebuilt, and various parts of the mill proper overhauled, while the fact that there is nothing to make public after 8 months run is a good criterion of the metallurgy attempted. It is but fair to say that Mr. Clancy did not have charge of the work at the Ajax, hence it is not certain that it was the Clancy process that was standing trial.

Of the lesser mills, those treating oxidized ores chiefly, the Kavanaugh at the Joe Dandy mine has had a most successful year and is reported to have returned its cost to its owners in 10 months operation. The Blue Flag mill of the Blue Flag Mining Co. has handled about 4000 tons during the year and is apparently successful, while the Wild Horse mill has maintained its regular rate of 50 tons per day, at a profit. An increase in the amount of low-grade ore handled in the district may be expected, and, in all probability, more mills along the lines of the Stratton's Independence and new Portland will be erected. Some sort of showing will probably be made by the Ajax mill with the Clancy process, so that, metallurgically, the outlook is bright.

JOHANNESBURG, TRANSVAAL

COAL-MINING INDUSTRY.—TIN MINING.

It is not generally recognized that the coal-mining industry of the Transvaal has become second only to gold in importance and total value, having now passed the diamond-mining industry. This is entirely due to the steady growth of the business transacted, for the selling price per ton of Transvaal coal has continued to decline. In October, 426,277 tons of coal was sold at prices at the collieries ranging from 3s. 9d. to 5s. 2d. per ton in the different districts.

Tin has had an unexpected setback in the Transvaal, for in October the value of the concentrate shipped was only £28,940, which, as a matter of fact, despite the higher prices now ruling for tin, is little more than half the highest total monthly value of concentrate shipped a year ago. For the past two years it has been confidently expected that the tin-mining industry of the Transvaal was in for some good times; in fact, nothing short of a 'boom' was at one time predicted, and large tin-mining areas in the Northern Transvaal were in consequence secured. Tin-mining in the north has, however, fared badly, largely due to the erratic manner in which the metal occurs. Several mines have started under what seemed at first promising conditions, only to find that the tin deposits were very irregular, and 'ore in sight' could only be considered tantamount to 'ore at grass.' There are only two mines of any importance now producing tin in the Transvaal; one, the Rooiberg, is a fairly consistent producer, while the other mine, at Zaaiplaats, by far the richer of the two, is quite the reverse. Some time ago the consulting engineer, in consultation with the acting manager, estimated the ore reserve as 114,000 tons of 4.5% tin, but a year's milling has shown that this calculation of the consulting engineer was overestimated to the extent of 69,670 tons. It was the same consulting engineer who, in reporting upon the prospects of the first discovery of tin in the Transvaal, ten years ago, at Vlaklaagte, made the astounding assertion that the Vlaklaagte tinfields would more than rival in importance the goldfields of the Rand. After a few months' prospecting, the tin gave out at Vlaklaagte and the field is now completely deserted. At the present time, owing to the erroneous estimate of the tin reserves at Zaaiplaats, the shares have fallen from £4 to about £1, and considerable injury has been inflicted upon what promised at one time to become an important tin-mining field in the Transvaal. Whether the field will recover from the effects of this mistake will depend to a large extent on future discoveries, but today's experience is that, where so many disappointments have occurred, there is little disposition to supply the capital needed to make such discoveries.

MEXICO

PETROLEUM PRODUCTION.—SALE OF THE PALOMA AND CAHRILLAS.

The petroleum production of Mexico in 1912 is estimated by Thomas H. Bevan, vice-consul at Tampico, at 20,000,000 bbl. He reports that in the first 9 months of the year the exports of Mexican oil to the United States totaled 4,237,307 bbl., with an invoice value of $2,632,911. The big wells of the Tampico territory show no signs of diminishing supply, and as new wells are being brought in and the facilities for marketing oil abroad are being increased, the output during the present year is certain to be much greater than in the year just closed. The gross sales of the Doheny interests in November amounted to $451,349, as against $353,887 in October and $324,759 in September. These companies expect to increase their exports to the United States this year, and to make important shipments to Brazil and other South American countries. It is authoritatively reported that the British Government has made a contract with the Pearson interests for the delivery of 1,000,000 bbl. of oil for the British navy, and that 29 oil-tank steamers are now building in British shipyards for the Mexican trade. The majority of the steamers are for the Pearson's Eagle Oil Transport Co., which has just placed two of nineteen new tank steamers in commission. The Anglo-Mexican Petroleum Products Co., the export selling concern of the Pearson interests, has just secured from the Barbadoes Government an exclusive privilege, for 25 years, of maintaining a ship fueling station at Bridgetown, and it is stated that this will be the first of a chain of stations extending through the West Indies and along the east coast of South America. The report of Pearsons' Mexican Eagle Oil Co., the operating concern in Mexico, for the year ended June 30 last, shows a balance at the credit of the profit and loss account of $4,264,942.57. During the year the company acquired, by purchase and lease, over 20,000,000 acres additional.

POTRERO GUSHER, VERACRUZ.

The recent purchases of the Paloma and Cahrillas mines in the state of Coahuila were made directly by the American Metal Co., Ltd., which is closely associated with the

Peñoles Mining Co., the concern operating the principal mines and the smelter at Mapimi, Durango. The price paid for the Paloma was ₱2,000,000, and for the Cabrillas $1,200,000. The same company has taken working leases on the property of J. J. Murphy at Cedral, Coahuila, and on the Florida mine in the Bajan district of that state. Much interest attaches to the working option on the Noria mine in the Sombrerete district of Zacatecas, granted by the Noria Development Co. to the Camp Bird interests of London, which control the big Santa Gertrudis enterprise in the Pachuca district of Hidalgo. If the purchase is made it will mean heavy expenditures for extensive development and for mine and mill equipment. The completion of the Durango-Cañitas line of the National Railways, now under construction, will give a great impetus to mining operations in the Sombrerete district.

In December the El Favor Mining Co. shipped from the El Favor mine in the Hostotipaquillo district of Jalisco 386 tons of high-grade ore, having a value of ₱62,635, and milled 1143 tons of ore that produced ₱17,418 in bullion and concentrate. The total profit on the month's operations was ₱51,070. The company's 20-stamp mill ran 87% of the possible time, crushing a total of 1967 tons of mixed ores from the El Favor, Mololoa, and Mirador mines, all Makeever properties. The value of the bullion and concentrate produced was ₱43,874. The Amparo Mining Co., operating in the Etzatlan district of Jalisco, is putting in two additional Krupp tube-mills, making four in all. It is expected that the new tube-mills will make it possible to increase the tonnage handled from 7000 to at least 7600 per month. In 1912 the Amparo company earned a big surplus over its dividend disbursements of $240,000.

NEW YORK

COPPER METAL SITUATION.—COPPER PRODUCERS AND BUYERS. —GRANBY AND HIDDEN CREEK.

As a striking instance of a retreat by the strongest of financial powers, the recent movements in copper metal stand out. During 1906 and the early part of 1907, when copper metal climbed to record prices, the consumers for the most part helped the movement. The 'right about, face' in the attitude of the consumer exemplifies typically the general change in temper. The movement in copper which carried the metal, broadly speaking, from around 12c. to a recent high mark of 17¾c., has been fought stubbornly and almost universally by consumers, and this unyielding attitude is emphasized by the fact that recent concessions which have brought quotations down to 16c. have signally failed to enlist any but the most grudging support. It is hard to imagine how a situation could have been more frequently or more thoroughly analyzed, and it seems wonderful, even at this time, after an incomplete but decided retreat has been made, that the stand taken by the consumer could have to this extent triumphed over an organization so strongly entrenched and commanding such limitless resources. It is quite evident that a common meeting ground for the opposing forces in copperdom has not been reached, and the peg will have to be moved still lower before the buyers will come into the market in anything like their wonted numbers.

The Shattuck-Arizona has made itself a feature of the Boston market by officially announcing the opening of a very rich body of copper ore on its 300-ft. level, the ore carrying a high content of silver. To make the news really worth while, the company is paying a dividend of 50c. per share and will soon be increasing its earnings by added shipments when the enlargement of the Calumet & Arizona smelter is completed. The Chino dividend is still a matter of rumor. There has been some talk of a quarterly payment of $1 per share, but the market action of the stock would seem to indicate a smaller disbursement. The figures of the U. S. Geological Survey covering copper production for the year 1912 estimate copper output for the year at considerably above any record in the history of the industry, being 1,249,000,000 lb., as compared with 1,097,232,749 lb. in 1911.

The Granby has been so successful in its 'coming back' that it would seem that the last word had several times been written. In December 1910 Granby paid a dividend of 1%, since which time the shareholders have been without returns upon the investment, and in addition have had to go through some rather nerve-racking experiences. After several meetings and some lengthy considerations, the directors have declared a dividend of 1½%, and what is of even greater importance, have issued a call for a special meeting to ratify the issuing of $5,000,000 in 6% ten-year convertible bonds. It has been a much-discussed question as to whether the Granby's new developments at the Hidden Creek property should be paid for out of earnings and the stockholders be deprived of all revenue, or whether there should be some new financing. It is now stated that this latter course has been decided upon, only because of the magnitude of the showing at the Hidden Creek mines. The statement is made that the ore developed at the Hidden Creek mine has a value greater than that of the ore mined from the Granby property since the beginning of operations. Granby's production has ranged from 14,000,000 to 21,000,000 lb. per year since 1905. On this basis there would have to be developed in the new property ore that would produce some 150,000,000 lb. of copper to make good this statement. Taking into consideration the comparatively short time which has so far been spent in the development of the Hidden Creek, this property will have to be immediately recognized as one of the potential big producers of new copper. Granby's new bond issue has been underwritten, and only $1,500,000 will be issued at this time, the remainder to be used as needed. These bonds are to be convertible into common stock at par.

Of especial importance to mining interests in the larger sense is the outlook for silver. The consensus of opinion seems to be that silver producers may expect a continuance of present prices and possibly some slight enhancement rather than otherwise. Purchases by the Indian Government in 1912 amounted to £6,000,000, this being the first silver bought for coinage into rupees since 1907, and, notwithstanding the recently developed tendency of the Indian Empire to hoard gold, the commercially prosperous conditions of the Empire point to the necessity of further purchases for coinage during the coming year. An equally important, but possibly more uncertain element, is the situation in China. The recent unrest in that country has had its effect upon the volume of commerce, but with restored tranquillity the needs of the country are certain to be greatly augmented, as for some time to come it will be impossible for China to get on any kind of an organized credit basis.

Comment has been made in this column from time to time on the development of hydro-electric power, and the measures put into effect to create a new and greater demand for the product. Along this line it is interesting to note that the Washington Water Power Co., the headquarters of which are in New York, is making negotiations looking to a revival of the Republic mining district, Washington. The present plan includes the purchase of one or more of the larger mines and the erection of a concentrating plant large enough to treat the ores of the district. The Washington Water Power Co. is one of the organizations of White, Weld & Co. and controls the public utilities of Spokane, furnishing power from three power-stations on the Spokane river, having a capacity of about 70,000 hp. at present.

It is announced that the merger which was to take in the Giroux and the ground of the Copper Mines Co. has been declared off. This is something of a disappointment to Ely, as it was hoped that the new concern would build another smelter and fill a larger place as an independent producer of copper. The litigation brought by the Stewart Mining Co. against the Ontario has ended adversely for the Heinze company. Shareholders who got in on the recent rise in the stock have been disappointed in the failure of the company to take any definite action in regard to dividends. The Stewart company has been operating a

mill owned by the Federal Mining & Smelting Co., and it is now stated that as the Federal is likely to need greater milling capacity, the Stewart may be compelled to erect a new mill of its own.

SEWARD, ALASKA

Willow Creek.—Road Construction.—Power and Fuel Supply.

Willow creek, in the Susitna River district, was first prospected by the Barthoff brothers about seven years ago, who discovered the claims which now comprise the property known as the Gold Bullion Mining Co. This discovery was shortly followed by others made by Robert Hatcher, and other prospectors, of claims now owned by the Alaska Free Gold Co. and the Alaska Gold Quartz Co., on Fishook creek, a tributary of the Little Susitna river. Later discoveries were made on Arcnangel and Fairangel creeks, which really form the headwaters of the Little Susitna river. Willow creek is a tributary of the Big Susitna river, emptying into that river from the east.

This district covers an area of about ten miles east and west and about two miles north and south. It is one of the most mountainous in southwestern Alaska, the ranges being extremely rugged and precipitous. The prevailing country rock is a variety of granite, and the orebodies occur in fissures of varying widths from a foot to about two feet. These can be traced by their outcroppings for very long distances without a break. On Willow creek and Fishook creek the dip of these veins, so far as it has been exposed by working, is quite flat, but on Archangel and Fairangel creeks the dip varies from 36 to 70 degrees.

The first gold produced from the quartz in this part of Alaska came from Willow creek, where the surface ores were so extremely rich that in 1909 there was quite a stampede to secure properties. Small stamp-mills were erected on the Gold Quartz and Free Gold properties so that during the season of 1912 they, in addition to the Gold Bullion, were regular producers. These properties were recently examined, but owing to the fact that the Free Gold had been leased for a term of years and that satisfactory arrangements could not be perfected with the lessee, it is reported that the deal has fallen through. From the best information obtainable, production to date from these three properties is in the neighborhood of $150,000.

Until last year the only means of transportation to any of these properties was by pack train, and the fact that they are all six or seven miles from any timber as well as the fact that the mills are run by water-power furnished by small streams, is the principal reason why operations have never been conducted except during the summer months, which of course is a serious handicap. During the summer of 1912 the Alaska Road Commission constructed a first-class wagon-road to connect these properties with tidewater at Knik, some 35 miles distant, and it was the expressed intention of Milo Kelly, the manager of the Alaska Gold Quartz Co. to construct permanent buildings during the coming season and make arrangements to operate in future during the winter. The three companies, it is understood, are endeavoring to come to some arrangement to develop hydro-electric power on the Little Susitna river for the generation of electricity and a transmission system not only to their own properties but also to any others in the district, as the flow of the stream to be developed is ample to furnish motive power for the entire district.

Although development work on the claims on Fairangel and Archangel creeks has been almost insignificant in quantity, yet the outcrops of good-grade gold-bearing quartz, worth $15 to $100 per ton, are sufficiently extensive and persistent to warrant the owners in carrying on much more extensive and systematic development. During last summer an orebody was discovered on a property near Fairangel creek that is apparently an extension of a narrow vein that had already been prospected on an adjoining claim about 1800 ft. distant. But an enormous rock slide that in places reaches a depth of 100 ft. prevents any prospecting to determine whether the latest discovery is an extension of the earlier one. During last season considerable prospecting was done by old timers and several locations were recorded on which gold-bearing quartz was discovered. Assay returns from samples invariably showed the ore to be high grade, but the extent of the bodies so far as at present known indicate a number of small mines rather than large bodies of ore.

The fact that the Matanuska coalfields are situated only about 20 miles east of the headwaters of the Little Susitna river is another reason why not only this district but the entire Kenai peninsula from Seward to the Talkeetna should receive attention from prospectors and capitalists. Of course the withdrawal of coal lands and the cancellation of entries has worked a hardship, especially in this district, so as to cause capital in the past to be averse to making investments, but everybody hopes that this policy will soon be changed. When that is done and mine owners can procure the necessary fuel at reasonable cost, the fact that a quartz mine is seven or eight miles from timber will be immaterial.

BUTTE, MONTANA

Butte & Superior.—Electrifying the Milwaukee.

The zinc concentrator of the Butte & Superior Copper Co. is now treating about 500 tons per day of ore averaging close to 20% zinc. The extraction, independent of the flotation plant, averages 70% of the zinc content, and 50% concentrate is being shipped to Bartlesville, Oklahoma. As it is generally conceded that the mine has in the neighborhood of 2,000,000 tons of ore which will average 18% zinc, the property gives promise of soon entering the dividend class.

As the plans for electrification of the Chicago, Milwaukee & St. Paul railway become matured, it is evident that they represent some big advances in transportation ideas and power economy. The system is being evolved by capable experts, and success is probably beyond question. It is apparent that the present work is only preliminary to the final electrification of all the Milwaukee lines throughout the West, and no doubt the other railways will follow suit just as soon as they realize the success of the system, and as soon as they can make the necessary arrangements for power. Of course, the hydraulic power available is not sufficient to operate all the railways, but the railways will probably be electrified just the same, additional electric power being furnished by power-plants at the coal mines. These changes herald the way for the use of Western coals in gas-engines in place of the present wasteful steam-engines. For the time being, however, railway electrification will mean curtailing Western coal production.

Some features in the Milwaukee plans are worthy of mention. The braking of trains on the down grade is to be accomplished by running the motors on the engines as dynamos, feeding the current thus generated back into the transmission systems. This will mean smoother movement than with the present friction-brake system, and will be a factor in power economy. The 3-phase alternating current from power-plants will be transmitted at 100,000 volts to numerous rotary transformers along the railway lines. From the transformers direct current will issue to the feeding lines at 2400 volts. Overhead trolley wires have been selected in preference to the third-rail system, which would be troublesome to operate in the deep snows of winter, and is more dangerous. The change to electricity over the 450 miles of main line from Harlowtown, Montana, to Avery, Idaho, will be completed in three years at an estimated cost of $8,000,000. A standard type of locomotive will be in use for both passenger and freight trains. These locomotives will be able to handle the regular trainloads of 2200 tons on a 1% grade, using an additional engine for steeper grades.

Several important economies are claimed for the new system. The present steam locomotives require inspection and overhauling after each 125 miles run; the new electric locomotives can run more than twice as far without inspection. While waiting for trains, steam locomotives consume 80% as much coal as they do when pulling a train; electric locomotives consume power only when in operation.

General Mining News

ALASKA

Valdez

The Fidalgo Alaska Copper Co. recently made a shipment to the Tacoma smelter and will probably continue to make regular shipments from this time.

The George W. Sals Syndicate, of Boston, has made a payment of $147,000 on 14 claims on Valdez creek, bonded some time ago. The same people have an option on 20 bench claims near the same creek, $10,000 on each claim being due on January 1, 1914. Competent engineers report that the extensive gravel deposits on Valdez creek will average 50c. per yard. So far work has only been done in a desultory manner.

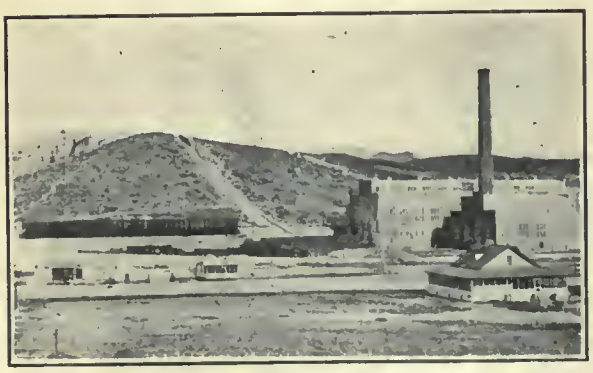
ARIZONA

Cochise County

The Shattuck mine produced 1,105,526 lb. of copper, 9538 oz. of silver, and 16 oz. of gold in December, and shipments to the Calumet & Arizona smelter at Douglas total 250 tons per day. When the new plant of the Calumet & Arizona is finished, the output will be 500 tons per day, under a five-year contract. Lead ore is being sent to El Paso from the 300, 400, 500, and 600-ft. levels, and it returns 40% lead, 3% copper, and $7 per ton in gold and silver. About 500 tons per month will be shipped. The mine employs 225 men, 190 being underground, and development covers 900 ft. per month. On the 300-ft. level a rich ore-shoot was recently opened, yielding 30% copper and $25 per ton in gold and silver.

Gila County

(Special Correspondence.)—At present the Inspiration Consolidated Copper Co. is employing 270 men underground



MIAMI POWER-PLANT.

and 40 on surface work. This force is merely employed at the preparatory mining work, the hundreds of men engaged in the mill construction and railroad grading being employees of contractors. The last measurement taken in the inclined shaft showed it to have reached its objective point, the 3480-ft. or upper tram level. It has been decided to continue the inclined shaft to a depth of 100 ft. below the upper tram level for the purpose of permitting a raise from that depth to the 3480-ft. level, where a 180-ton waste-pocket will be cut, the waste to be dropped through the raise and lifted through the inclined shaft to an npper level, through which it will be conveyed to the surface. At the millsite the steam-shoveling and blasting already have made heavy inroads on the 300,000 cu. yd. of earth which must be removed before H. Kenyon Burch can hegin construction on the 7500-ton mill. Fourteen draftsmen are engaged in the task of designing the plan and details of the concentrator. Because of the similarity of ores in the Inspiration and Miami properties, the Inspiration will be modeled to a great extent upon the plan of the Miami concentrator.

The completion of the new 500-ton unit of the Old Dominion concentrator depends on when the shipments of steel come through from the East, but if there is no delay the concentrator will be running in the late fall of this year. Excavation for the crusher plant is completed, and the forms are in place for the concrete. Excavation work is proceeding at the site of the sampling mill and concrete ore-bins. The foundation for the new Nordberg compound-geared hoist at the 'A' shaft was completed early this month, and is ready for the hoist, which has been delayed in shipment. There are no new important developments underground to report, although work has been started cutting pockets on the 800 and 1200-ft. levels. The ore-bins at the Kingdon shaft consist of four 100-ton capacity pockets, or 400 tons in all. A new air-line will be laid from the O. D. smelter power-plant to the Kingdon shaft, and the air will be reheated before use in the hoist.

Miami, January 25.

During December, development at the Inspiration Consolidated mines covered 3780 ft. in the Inspiration and 470 ft. in the Live Oak area. The drifts being driven to connect the Joe Bush and Scorpion shafts have made connection. Under 1100 ft. remains to be driven to connect the drifts between the Colorado and Scorpion shafts. Surface work for the railroad construction, grading of millsite, and erection of buildings continues with much energy. At the Miami, Chilean mills are being replaced by Hardinge conical mills. In the Superior & Boston mine, development is being done on the 600, 800, and 1000-ft. levels. The Gibson Copper Co. shipped 262 tons of 18% copper ore to the Old Dominion smelter at Globe in December. The raise for the 600 to 400-ft. level is finished. The Summit adit is in 800 ft., and will be driven to connect with the Summit shaft, from which the Pasquale vein will be opened.

In December the Iron Cap produced about 450 tons of ore averaging 6.5% of copper and 4.5% of iron, and sent it to the Old Dominion smelter. The Williams shaft is 800 ft. deep, and 35 men are employed. The shaft of the Arizona Commercial Co. has been repaired to 800-ft. depth. A large steel head-frame has been removed from the Eureka to the Copper Hill shaft. In a north drift from the adit, the new Dominion mine has opened 12 in. of chalcopyrite assaying 23% of copper. The Magma Copper Co. is opening rich bornite ore on the 800-ft. level.

Mohave County

The United States Smelting, Refining & Mining Co., which owns the Gold Road mine, is employing 200 men, and the monthly yield is over $70,000. The mine shows an ore-shoot 300 ft. long, and during the current year the company expects to make good profits.

Pima County

C. A. Schrader, who has recently visited the Ajo district, 80 miles southwest of Tucson, states that 400 men are working there. The Calumet & Arizona company has six diamond-drills working, while other companies are prospecting claims.

Santa Cruz County

At the Chiefs mine, in the Patagonia district, an adit was driven to cut the World's Fair vein, and at 411 ft. 5 ft. of ore averaging 48% of lead and 1600 oz. of silver was opened. A winze sunk 28 ft. is still in ore, and at 75 ft. stoping will be started and ore sent to El Paso. The present workings are about 280 ft. above the World's Fair. The latter's owner, F. Powers, has let a contract for 500 cords of wood.

Yuma County

At the Swansea smelter a reverberatory furnace, 19 by 108 ft., is being built, and the monthly production of copper is 600,000 lb., mostly from custom ores.

CALIFORNIA

Amador County

During the six months ended December 31, 1912, the Bunker Hill mill crushed 34,941 tons of ore in 176 days. The condition of the mine is satisfactory, and dividend No. 79, of 5c. per share, was paid on January 15.

Inyo County

The 20-stamp mill of the Skidoo mine has been shut down

owing to the 29-mile pipe-line bursting in several places, due to the reecnt cold weather. The water for the Skidoo district comes from Jail canyon at the foot of Telescope creek, across the desert, at a high pressure.

HUMBOLDT COUNTY

(Special Correspondence.)—The Oro Water, Light & Power Co. has taken 15,000 acres of gravel land under lease from the Orleans Mining & Development Co., and is arranging to prospect with a Keystone drill. The larger portion of this area has been worked by hydraulic methods by the Orleans company, but large deposits of the gravel are at a depth unsuitable for extraction by this method. About 1000 acres comprises virgin ground, and has been extensively hand-drilled. If prospects prove sufficiently good, the Oro people plan the erection of a bucket-elevator dredge, costing approximately $75,000. It is understood the company is contemplating the building of an electric-power plant, as abundant water is available. This marks the first practical attempt to dredge gold placers in this county, and the project is arousing considerable interest. The property is situated near Orleans, at a point close to the Siskiyou county line.

Eureka, January 18.

KERN COUNTY

(Special Correspondence.)—Andrew Nixon reports the discovery of a rich vein of white scheelite in his recently acquired White Flower property. A shaft is being sunk. The Atella Mining Co. is developing the Churchill and East Union claims. The former has been opened to a depth of 600 ft., and the latter about 250 ft., by shafts. The mill is operating steadily with three shifts. It is reported the Yellow Aster Mining Co. is contemplating a further increase in its working force. The company has paid $1,111,879 in dividends, of which $50,000 was disbursed in 1912.

Randsburg, January 19.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—J. C. Bell & Co., owners of the Josephine mine on Kelso mountain, are considering the construction of a small blast-furnace to treat the lead ore exposed. It is stated that a force of 30 men will be at work by March 1. Connors & Co., leasing on the La Plata mine on Democrat mountain, started a shipment of 15 tons of first-class ore this week. Returns of 400 oz. of silver per ton are expected. S. L. Work, operating the Pioneer mine on Covode mountain, is operating the new 10-stamp mill on one 12-hour shift. A high saving of metals is reported.

Georgetown, January 20.

At the Capital mine both the company and lessees are busy on development, and mining ore. Three cars of ore worth $20 per ton have been shipped from the Gold Fissure mine on Covode mountain. The new mill of the Pioneer mine has been started. The Josephine mine at West Argentine has 3 ft. of ore averaging 60% of lead, and shipments have been sent out.

DENVER COUNTY

(Special Correspondence.)—The annual meeting of the Colorado chapter of the American Mining Congress was held at the rooms of the Colorado Scientific Society, Denver, on January 21. The retiring president, D. W. Brunton, delivered an instructive address. The following officers were elected for the current year: Governor, S. D. Nicholson, of Leadville; first, second, and third lieutenant-governors, respectively, J. M. McClave of Denver, A. L. Burris of Cripple Creek, and Bulkeley Wells of Telluride; executive committee, V. C. Alderson of Golden, R. L. Martin of Central City, and Thomas Tonge of Denver; secretary and treasurer, E. L. Wolcott of Denver; directors, D. H. Brunton of Denver, F. W. Bosco of Creede, E. A. Colburn of Denver, R. D. George, State Geologist, of Boulder, A. W. Harrison of Silverton, R. M. Henderson of Breckenridge, Irving Howbert of Colorado Springs, W. E. Renshaw of Idaho Springs, J. T. Roberts, Jr., of Ouray, and G. S. Wood of Cripple Creek. A resolution was adopted to the effect that the mining industry, dating from 1860, had done more to build up Colorado and Denver than any other industry, and the people of the state and city are urged to take a more intelligent and unprejudiced interest in legitimate mining. The executive committee is to arrange for monthly luncheons, to which all mining men will be invited.

Denver, January 22.

LAKE COUNTY (LEADVILLE)

The Sharver-Cullen lease at No. 2 shaft of the Ibex, has cut about 18 ft. of zinc carbonate ore averaging 18% of zinc. Several cars of ore from the recent development of the Mt. Champion group, Lackawanna gulch, returned $135 per ton at the Arkansas valley plant. This ore is 6 ft. wide, and a cross-cut is now in 15 ft. The orebody in the upper adit has been opened for 400 ft., and with the opening of this vein in the lower adit, there is 120 ft. of stoping to be done.

SAN MIGUEL COUNTY

The Tomboy mill treated 11,000 tons of ore during December yielding $15,500 and $75,500 from 1650 tons of concentrate, a total of $91,000. Expenses were $50,500, leaving a profit of $40,500. Construction costs were $1033, and expense on aerial tramway, $5400.

TELLER COUNTY (CRIPPLE CREEK)

To drive a fourth drainage tunnel, 500 ft. below the Roosevelt tunnel, will cost about $450,000, and toward this the different railroad companies operating in the district have subscribed $100,000, and the Cresson Consolidated company $50,000. The Elkton and El Paso companies are considering the question, while the Portland company will not contribute until its ore-shoots are developed to the level of the present drainage tunnel.

During 1912 the Isabella company sank its shaft 200 ft. and cross-cut 300 ft., and depended upon royalties from lessees to pay for development. Development of the rich shoot opened on the 1500-ft. level of the American Eagles mine proves the ore to be continuous, and returns have averaged $40 per ton. Rosebud hill, and that section adjacent to Beacon hill, is to be prospected, and the district should soon be active. The Cresson shaft is down to 1300 ft., and cross-cutting has been started to the orebody. A winze has been sunk in ore from No. 12 level.

IDAHO

SHOSHONE COUNTY

The 60-ton concentrating plant of the Sierra Nevada has started work. The Marsh mine at Burke is opening well, and 65 men are employed in sinking a 3-compartment shaft from 800 to 1000-ft. depth. When this is finished, a raise, which has already been started from the shaft station, will be driven through the 500-ft. level to the main adit, providing a 3-compartment shaft to the 1000-ft. level. An electric trolley line will then be installed from the adit portal to the shaft station. The Hecla Mining Co., of Burke, has declared dividend No. 115, of 2c. per share, amounting to $20,000, making a total of $2,670,000. During 1912, dividends were $300,000.

MICHIGAN

HOUGHTON COUNTY

During its past fiscal year the Ahmeek Mining Co. showed the following results:

Ore milled, tons	651,329
Copper produced, pounds	16,476,000
Yield per ton	$25.3
Cost per ton	$1.39
Cost per pound, excluding construction	5.50c.
Cost per pound, construction	1.22c.
Cost per pound, smelting, freight, office, etc.	1.15c.
Total cost per pound refined copper	7.87c.
Net earnings	$1,520,000
Dividends paid	900,000

The Isle Royale mine produced 8,200,000 lb. of copper in 1912, at a cost of 9c. at the mine and a total of 11.25c.

per pound, the average price received being 16.75c. per pound. Net profits were $520,000, and the surplus is now $768,000.

MONTANA

Silverbow County

(Special Correspondence.)—Some of the machinery for the Butte Central mill has not yet arrived, but by February 15 the plant ought to be in operation. While a number of special features have been included, there has been no radical departure from the practice in other places where concentration and all-sliming methods are used. A large number of preliminary tests have been made on the ore of this mine. The most interesting feature of the mill will be the working of the counter-current method of continuous agitation, in which the highest grade of solution from the first agitator will be drawn off, while the pulp passes continuously through the series, meeting a barren solution at the last agitator, thus getting both a dilution of the pulp going to the filter, at the same time bringing a solu-

MINES AT BUTTE.

tion high in free cyanide, and low in metal content from the last agitator up to the first, this solution building up in metal value as it makes the circuit.

Butte, January 22.

The leaching plant of the Butte-Duluth company is nearing completion. It will have a capacity of 200 tons per day, and the process is similar to that at the Bullwhacker, where results have proved satisfactory. The concentrating plant of the Boston & Corbin company will be ready for work about the middle of the present month. The Anaconda Copper Mining Co. will add to its mining equipment at Black Eagle station, seven 25-ton and two 10-ton electric mining locomotives, supplied by the General Electric Company.

In December the East Butte Mining Co. produced 1,316,962 lb. of copper, and during the past year, a total of 14,747,086 pounds.

NEVADA

Churchill County

During December the Nevada Hills Mining Co. treated 3596 tons of ore yielding $72,730, the loss in tailing being $6370. Costs of mining and treatment were $31,606, leaving a profit of $34,854. Construction expenses were $2646. Assets of the company total $130,500, including cash, $14,600; concentrate and bullion in transit, $32,500; supplies, $55,000; and absorption of metals in mill, $23,000; while liabilities total $100,000.

Esmeralda County

About 40 men are working in the Klondyke district, and James Golden is in San Francisco arranging for a mill of 50-ton capacity. A well is being sunk for water supply for the mill, and town of Klondyke.

Humboldt County

A new mining district has sprung up at Poverty Peak, situated at the western edge of the mountain of that name, and is the turning point of the Little Humboldt river in Paradise valley, and is 30 miles north of Winnemucca, connected by a good wagon-road. Free gold has been found at the foot of the mountain. The orebodies are in an altered porphyry, in limestone. A number of claims have been staked.

Nye County

The Nevada Cinnabar Co. was recently organized, with a capital of $1,000,000, in Utah, for the purpose of developing quicksilver properties in this state. The company has acquired the Davis, and Shoshone Quicksilver Co.'s mine, making a total area of 50 acres. Near these claims there is a 25-ton furnace in operation, and good profits are made.

Storey County

On the 1000-ft. level of the Consolidated Virginia, the northwest drift was advanced 80 ft., including six sets of timber, during the week ended January 25. The face of the drift is in porphyry. In the Ophir, work has been confined to general work on the 1600, 2400, and 2500-ft. levels. Work on the 2500-ft. level of the Sierra Nevada has been temporarily suspended owing to an accident to the motor of the Union-Sierra Nevada joint winze. The Yellow Jacket mill has been working full time on Crown Point, Belcher, and Yellow Jacket ore. The Mexican mill ran 70% of the time and treated 315 tons worth $30.39 per ton, with 93% extraction. No. 1 tube-mill is out of commission owing to the motor burning out. The pumps at the C. & C. pumping shaft were only stopped 15 min. owing to shortage of power.

White Pine County

The Nevada Consolidated Copper Co. will pay bullion tax amounting to $13,284 on net profits for the last quarter of 1912, when the following were the results of operation:

Ore treated, tons	515,115
Gross yield	$2,375,072
Cost of mining	389,662
Cost of freight	135,041
Cost of treatment	1,218,807
Net yield	632,562

The tax rate is $2.10 on each $100 of net profit.

OREGON

Baker County

A peculiar case has been started at Baker by W. Mortison against the Columbia company for $100,000. His son lost both legs through, it is alleged, his wading through the water of Crack creek, which is polluted with 'acids' used in the cyanide process at the mine.

Jackson County

The Sterling mine, eight miles southwest of Jacksonville, one of the richest placer mines in southern Oregon when in operation, is to be reopened by S. S. Bullis and his son, of New York. A ditch for hydraulic work has been surveyed, and will be constructed. The mine has been shut down for four years.

UTAH

The following production of coal was made in 1912 by the coal companies of Utah, as published by W. H. Child & Co. in the Salt Lake *Tribune:*

	Tons.
Utah Fuel Co. (controlled by D. & R. G. railway)	1,951,784
Castle Valley Coal Co.	210,395
Consolidated Fuel Co. (controlled by United States S. R. & M. Co.)	319,777

Blackhawk Coal Co.	99,976
Independent Coal & Coke Co.	401,316
American Fuel Co., mine ready for daily output	1,000
Spring Canyon Coal Co. (controlled by J. Knight), daily	1,000
Castle Gate Coal Co., mine being developed, daily shipment	50

The National Fuel Co., now being financed, has 1040 acres in Carbon county.

Juab County

The annual report of the Lower Mammoth Co. states that development during the six months ended December 31, 1912, covered 1900 ft., and a good deal of low-grade zinc ore has been opened on the 1300, 1400, 1500, 1700,, and 1800-ft. levels. Probably 150,000 tons averaging 12% zinc, or about $17 per ton. Experiments are being made on this ore with a view to its profitable treatment. One car of copper ore and 10 cars of zinc were shipped, 538 tons in all, worth $8716. Including assessments of $20,000, the revenue was $36,052, and expenditure $29,798; while after paying off an overdraft, the cash on hand is $1162.

Salt Lake County

The Utah Apex Mining Co. will soon have in use a new 3-ton electric mining locomotive recently ordered from the General Electric Co. The Utah Copper Co. produced 5,975,246 lb. of copper in December, making the year's total 95,015,391 lb., against 99,456,225 lb. in 1911, the decrease being caused by the strike last September.

A special meeting was to have been held on January 30 of the Consolidated Flagstaff, Superior-Alta, Columbus Consolidated, and Columbus Extension mining companies of Alta, to ratify the action of the directors in agreeing upon a consolidation of these properties. The consolidation will control 700 acres of mineral land under the name of the Wasatch Mines Co., with a capital of 1,000,000 shares of $5 each, of which the Columbus Consolidated will have 160,000; Columbus Extension, 100,000; Flagstaff, 100,000; and Superior-Alta, 40,000 shares. The treasury shares will be used to raise money for driving an adit, and development of the lower levels of the various properties.

Within the next 30 days the crushing department of the Utah Copper Co.'s mill will be completed, giving a capacity of 50,000 tons per day, which is far in excess of the capacity of the mills.

Tooele County

The copper smelter of the International Smelting & Refining Co. is still shut down, although there is about 25,000 tons of copper ore at the plant. The lead smelter is being operated full time.

WASHINGTON

Ferry County

The examination of the San Poil, Old Republic, and Ben Hur mines at Republic, in compliance with the agreement under which the properties were recently optioned under the direction of the Washington Water Power Co., is to begin at once, and J. V. Richards, of Spokane, who represents the option holders, has gone to the district with assistants.

Stevens County

Conrad Wolfle, manager of the United Copper and Aurora mining companies, has announced that the companies have entered into a 10-year contract with the West Kootenai Power & Light Co. for 1000 hp. at $40 per horse-power. By May 1, 250 hp. is to be delivered, being supplied from the plant at Meyers Falls, on the Colville river, recently acquired by the Kootenai company. The remaining 750 hp. is to be delivered within two years from the big plant at Bonnington Falls and covers the remaining 10 years of the contract.

WYOMING

According to the *Centennial Post*, the production of this state in 1912 was: agriculture, $35,820,000; stock-raising, $30,465,000; mining, $24,860,342; and manufacturing, $6,000,000; while the resources of the state are calculated at $47,692,000,000, of which coal, oil, phosphate, iron, gold, and copper lands are set down at $45,300,000,000.

CANADA

British Columbia

During the week ended January 22 the Granby smelter at Grand Forks, treated 22,318 tons of ore and 370,000 lb. of blister copper was shipped. The totals for the first three weeks of 1913 are 65,654 tons of ore and 1,088,000 lb. of copper.

GRANBY SMELTER.

Ontario

(Special Correspondence.)—A deal of unusual importance was negotiated recently when the holdings of the Dominion Nickel Co. in the Sudbury field were acquired by F. S. Pearson. The Dominion Nickel Co. is owned by J. R. Booth and M. J. O'Brien, and it controls large areas of valuable mineral land in the nickel range. Mr. Pearson has for years been intimately associated with Sir William MacKenzie in connection with his electric power-plants in Canada and Mexico, but it is understood that the new company will be financed by the Rothschilds. The Guggenheims had been negotiating for months for the purchase of the Dominion Nickel Co.'s holdings, but satisfactory terms could not be agreed upon, and the way was left open for Mr. Pearson and his associates. No details regarding the terms of purchase are available, although a large payment has already been made, but it is believed that the figures will run into millions. So far the International Nickel Co. has had practically a monopoly in the nickel business, the Copper Cliff mines, near Sudbury, producing nearly 70% annually of the world's supply. This company is now starting to double the capacity of its smelter and expects in two years time to be treating 160,000 tons of ore per month. The market for nickel has been constantly broadening, and it is doubtful if the entry of this new company will have any effect upon the International Nickel Co. In order to successfully compete with them it will necessitate an expenditure of $5,000,000 to $8,000,000 and about five years time.

Sudbury, January 23.

During the week ended January 18, 11 mines at Cobalt shipped 469 tons of ore. Bullion shipments for the year to date total 182,450 oz., worth $115,379. La Rose Consolidated revenue in December was $163,128, making the year's total $1,796,880, and profit $1,026,663. The surplus at the present time is: cash, $1,667,104; ore on hand and in transit, $199,526; a total of $1,866,631.

Yukon

According to G. I. McLean, comptroller of the territory, the gold production of the district in 1912 amounted to $5,250,000, against $4,300,000 in 1911. Almost the entire output is from placer deposits, the first quartz mill in the Yukon, the Lone Star, only yielding a few thousand ounces. The bulk of the gold comes from Bonanza, Hunker, Eldorado, and the Klondike valley, where are the properties of the Yukon Gold Co and the Boyle Concessions, Ltd. About 20 other creeks contributed to the total production. The Yukon Gold Co. operated eight dredges and 15 hydraulic plants. During the coming season the number of dredges will be the same, but hydraulic work will be increased by

1200 in. more of water in the Twelvemile ditch. The Boyle company will increase its dredges from two to four, the new ones having a capacity of 14,500 cu. yd. per day. The former company employs 800 and the latter 200 to 300 men. The total output of gold from the Yukon is approximately $169,000,000.

Skagway has a hydro-electric plant which cost approximately $70,000, including emergency boilers. The maximum output is 500 kw. per hour, and charges are 6c. for power and 10c. for lighting, with a monthly flat rate on lamps burning a certain number of hours. The Home Power Co., which owns and operates the lighting and water systems, furnishes the town with water at $100 per month, the town authorities retailing the water and making $300, charging $2 for the first tap and 25c. each for each subsequent tap. Hotels are charged 10c. per room for water, regardless of the number of taps used. The Alaska General Electric Co. owns and operates the telephone system, which has a radius of one mile and cost $3000 to install. The charge for telephones is $5 per month for business and $3 for residence.

MEXICO

Chihuahua

Owing to a shortage of coke, the Chihuahua smelter was shut down for two days, but resumed operations on receiving a shipment from the United States. This smelter employs 500 men, and deals with 800 tons of ore per day.

Durango

Sixteen Americans, at Inde, were threatened by bandits, who also stated that they would destroy the buildings and machinery of three large American and French mining companies. The Mexican Government sent 150 troops to give assistance. Inde is 70 miles overland from the railroad station of Rosario, Durango. It is the centre for the Inde, Guadalupe, and Matracal mining companies. The Durango Lumber Co. is starting its mills, which will have a capacity of about 5,000,000 ft. of lumber per month. A railroad about 10 miles long has been constructed to Durango. The rolling stock consists of 5 locomotives and 150 cars for transport of logs and finished timber to all parts of Mexico. M. A. Leach is general manager for the new company.

Hidalgo

The estimated production of the Real del Monte Co., of Pachuca, owned by the United States Smelting, Refining & Mining Co., for 1912 was 3,610,032 oz. of silver and 19,867 oz. of gold from the treatment of 40,000 tons of ore per month at the two mills. Profit from these operations was fully $1,500,000.

Mexico

The mill of El Oro Mining & Railway Co. treated 20,560 tons of ore and re-treated 16,670 tons of tailing during December, yielding a total of $177,620. Working expenses were $102,040, development $22,640, leaving a profit of $52,940, which, added to the railway profit of $9720, made a total of $62,660.

Sonora

A vein several feet wide and carrying 300 oz. of silver and gold per ton has been opened about 15 miles east of El Tigre. It is called El Tembior, and a 25-ton mill has been ordered. W. L. Rynerson, who has a lease on the mine, has shipped 20 tons of picked ore, averaging over 500 oz. of silver and 8 oz. of gold per ton, to Douglas.

During December the old mill at El Tigre crushed 3205 tons of ore and the stamp-mill 3416 tons, while the cyanide plant treated 6410 tons of current and 1051 tons of dump tailing, the total yield being worth $143,877. Expenses totaled $84,988, leaving a profit of $58,889. Since January 1, 1912, canceled notes and bonds worth $315,168 were purchased, completing the bond requirements to September 1, 1913. Dividends paid in 1912 were $379,128, making a total to date of $694,296.

Preliminary estimates for 1912 show that the subsidiary properties of the Mines Company of America made a gross production of $2,400,000, and expenses were $1,600,000. The Dolores, El Rayo, Creston-Colorado, and La Dura mines are in full operation.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

Jesse Scobey is in Nicaragua.

C. C. Broadwater has gone East.

A. L. Sweetser has gone to Mexico.

M. R. Campbell was here on Monday.

H. R. Beekman has sailed for London.

F. G. Cottrell has returned from the East.

Thomas Kiddie, of Victoria, is at the Palace.

R. P. Vincent has returned to Australia from England.

R. Y. Williams has returned to Urbana from Alaska.

C. H. Lindley is still in the hospital, but is recovering nicely.

Howland Bancroft was in San Francisco during the week and has gone to Los Angeles.

Clarke Sullivan has been appointed superintendent of the Zapilote mine, in Tepic.

S. J. Kidder, now superintendent of the Buckhorn mine, is visiting in the Middle West.

William B. Fisher has resigned as superintendent for the Davis-Daly Copper Company.

W. M. Bowman is assayer and chemist for the West End Consolidated Mining Co. at Tonopah.

R. B. Rogers was in San Francisco while returning from Honduras and has gone to New York.

H. Kenyon Burch is now engineer for the Inspiration Consolidated Copper Co., at Miami, Arizona.

Louis J. Mayreis is now with the South Urals Mining & Smelting Co., Tanalyk-Baimark, Orenburg, Russia.

J. P. Hart has left Tonopah to take charge of the Manhattan Ore & Milling Co. mill at Manhattan, Nevada.

C. F. Rand has been nominated for the office of president of the American Institute of Mining Engineers.

R. B. Oliver has returned from the Belgian Congo and is now at 2063 San Antonio avenue, Alameda, California.

Charles H. Lee is now at 934 Union Oil building, Los Angeles, where he has opened a hydraulic engineering office.

Bradley Stoughton has been nominated as secretary to the Board of Directors of the American Institute of Mining Engineers.

M. W. Atwater has resigned as superintendent for the Butte & Superior Copper Co. to become superintendent for the Davis-Daly.

Gelasio Caetani has left for Boston after delivering a course of lectures at Harvard University. He will go to Europe for a few weeks.

George E. Collins was re-elected president of the Colorado Scientific Society at the annual meeting recently. The new vice-presidents are E. N. Hawkins and Richard A. Parker. Frank E. Shepard and Thomas B. Stearns were elected to the vacancies on the executive committee.

F. Lynwood Garrison has been retained as chief engineer in charge of exploration of placer lands controlled by the Breitung Mines Corporation in Colombia. Mr. Garrison sails for Colombia on February 1, accompanied by a corps of four assistant engineers.

San Francisco Section of the Mining & Metallurgical Society will meet at Hotel Oakland next Monday, February 3, for election of officers and discussion of workingmen's compensation. A. J. Pillsbury will open the discussion.

Obituary

Edward C. Treadwell, superintendent of the Bonanza mine, in Trinity county, California, was swept away and killed by a snowslide on January 15. He was the son of James Treadwell, of San Francisco, and though but a young man had shown great promise.

LOCAL METAL PRICES

San Francisco is not a primary market for the common metals except quicksilver. The prices quoted below therefore represent sales of small lots and are not such as an ore-producer could expect to realize. Ore contracts usually call for settlements on the basis of Eastern prices, less freight and treatment charges. The prices quoted are in cents per pound, except in the case of quicksilver, which is quoted in dollars per flask of 75 pounds.

San Francisco, January 30.

Antimony	12—12½c	Quicksilver (flask)	39
Electrolytic Copper	18—18¼c	Tin	53½—54c
Pig Lead	4 60—5.55c	Spelter	8¼—8⅜c

Zinc dust, 1400 lb. casks, per 100 lb., small lots $9.50—9.75; large $7.50—8.50

METAL PRICES

(By wire from New York.)

NEW YORK, January 30.—Copper prices are decidedly unsettled; buyers are holding back for better terms despite the recent drop. Lead is quiet but in better demand. Spelter remains weak. Average daily prices for the past week, in cents per pound, based on wholesale transactions, standard brands, are given below.

Date.	Electrolytic Copper.	Lead.	Spelter. St. Louis	Silver, per oz.
Jan. 21	16.15	4.33	8.70	62⅛
" 21	16 05	4 33	6 63	62⅛
" 25	15.95	4.33	6 60	62⅛
" 26	Sunday.	No market.		
" 27	15.90	4.33	6 55	62⅛

December	143,353,280	58,490,880	65,712,640

SILVER

Below is given the average New York quotation, in cents per ounce, of fine silver for the months indicated:

	1912.	1913.		1912.	1913.
Jan.	56.25	63.01	July	60.67	....
Feb.	59.06	....	Aug.	61.32	....
Mch.	58.37	....	Sept.	62.95	....
Apr.	59.20	....	Oct.	63.16	....
May	60.88	....	Nov.	62.73	....
June	61.29	....	Dec.	63.38	....

COPPER

Daily quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally from 1-5 to 1-4c. per lb. more. Below are average monthly quotations in cents per pound:

	1912.	1913.		1912.	1913.
Jan.	14.09	16.54	July	17.19	....
Feb.	14.08	....	Aug.	17.49	....
Mch.	14.68	....	Sept.	17.56	....
Apr.	15.74	....	Oct.	17.32	....
May	16.03	....	Nov.	17.31	....
June	17.23	....	Dec.	17.37	....

LEAD

Lead is quoted ordinarily in cents per pound or dollars per hundred pounds delivered at St. Louis or New York. Below are the average New York quotations by months:

	1912.	1913.		1912.	1913.
Jan.	4.43	4.28	July	4.71	....
Feb.	4.03	....	Aug.	4.54	....
Mch.	4.07	....	Sept.	5.00	....
Apr.	4.20	....	Oct.	5.08	....
May	4.20	....	Nov.	4.91	....
June	4.40	....	Dec.	4.20	....

ZINC

Zinc is quoted as spelter, standard Western brands, and based upon St. Louis or New York delivery. While New York quotations, as a matter of convenience, are commonly used, relatively little spelter actually goes to or comes from New York. The bulk is shipped direct from the plants in the Mississippi Valley to manufacturers, due allowance being made for freight. New York daily quotations are published in this column each week. Below are given averages by months:

	1912.	1913.		1912.	1913.
Jan.	6.42	6.88	July	7.12	....
Feb.	6.50	....	Aug.	6.96	....
Mch.	6.57	....	Sept.	7.45	....
Apr.	6.63	....	Oct.	7.36	....
May	6.68	....	Nov.	7.23	....
June	6.88	....	Dec.	7.09	....

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average monthly quotations, in dollars, per flask of 75 lb., are given below:

	1912.	1913.		1912.	1913.
Jan.	43.75	39.37	July	43.00	....
Feb.	46.00	....	Aug.	42.50	....
Mch.	46.00	....	Sept.	42.12	....
Apr.	42.25	....	Oct.	41.50	....
May	41.75	....	Nov.	41.50	....
June	41.30	....	Dec.	39.75	....

TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations average about 5c. per lb. higher. Below are given average monthly New York quotations in cents per pound:

	1912.	1913.		1912.	1913.
Jan.	42.53	50.45	July	44.25	....
Feb.	42.96	....	Aug.	45.80	....
Mch.	42.58	....	Sept.	48.64	....
Apr.	43.92	....	Oct.	50.01	....
May	46.05	....	Nov.	49.92	....
June	45.76	....	Dec.	49.80	....

Current Prices for Chemicals

(Corrected monthly by Braun-Knecht-Heimann Co.)

Prices quoted are for ordinary quantities in packages as specified. For round lots lower prices may be expected, while in smaller quantities advanced prices are ordinarily charged. Prices named are subject to fluctuation. Other conditions govern Mexican and foreign business.

James Lewis & Son's Copper Report

The market for standard copper was subject to considerable fluctuation during December, with but little change at the close. In sympathy with a rapid depreciation in the value of the shares of the leading copper-producing companies, prices declined from £76 17s. 6d. for cash on December 2, to £73 5s. 0d. on December 16, and subsequently gradually recovered to £76 12s. 6d., this being the closing value of the year, against £63 at the end of 1911. Sales during December amounted to about 35,000 tons.

Consumers have bought refined copper sparingly, declining to pay the abnormally high price of 17¾c. per pound, or £82 per ton, c.i.f., demanded by the leading American refiners for electrolytic, supplying their requirements from other sources, English and Japanese, while some purchases from the smaller American producers have been effected at 17¼c. per pound.

Exports from the United States during December were 29,274 tons. This will include the excess of 'deliveries for export' by refiners over the custom house exports for November, of 5812 tons. A further considerable increase in American refiners' stocks at the end of December may be expected. Imports into Germany for 11 months amount to 191,993 against 176,525 tons in the same period of 1911; and the exports to 9050 against 8429 tons. The consumption of foreign copper is 193,778 against 169,796 tons, an increase of 23,982 tons. For the 10 months, the increase was 30,246 tons, showing a reduction of 6264 tons for the 11 months, as compared with the 10 months' period. European stocks have increased 785 tons, but the visible supply has decreased 40 tons during December. Imports are 4725 and deliveries 15,165 tons less than during the same period of 1911. Total arrivals in England and France for December were 18,820, and deliveries 18,352 tons fine copper. Arrivals in England from Chile were 2172 and deliveries 1983 tons, and from other countries 12,618 and 11,862 tons, respectively. Arrivals at Liverpool and Swansea from the United States were 2875 tons of bars and 630 tons of ingots, equal to about 3491 tons fine; in London, 311; and in France, 2190 tons fine. Chile charters are advised as 3300 tons, including 1325 tons for the United States.

ELMORE vacuum plant at the mines of the Sulitjelma company, Norway, produced 650 tons of copper concentrate during December.

Company Reports

TANGANYIKA CONCESSIONS, LIMITED

This company was originally formed in January 1899 to acquire a concession granted by the British South Africa Co. conferring the right to locate an area of 2000 acres in Northern Rhodesia, and other rights. Since that time copper and tin mines have been developed and smelting started, the metallurgical operations of which have been frequently the subject of much discussion; and interests taken in other companies and railroads, until the whole business is of a complex character requiring much study. The company holds 45% of the stock of the Union Miniere du Haut Katanga (Mineral Company of Katanga), whose general meeting was held in Brussels on December 2, 1912. Mr. Jadot, one of the directors, gave the following particulars of recent operations at the mines.

At the Star of the Congo mine, development is being carried out on proper lines, and discoveries made in shafts sunk 91 ft. below water-level are encouraging. At the Kambove mine, where 2800 ft. of adits and cross-cuts had been driven, necessary preparations are being made for extensive work, which, it is hoped, will be completed soon after the railroad from Elisabethville to Kambove is in operation. The other mines will be developed as the railroad is advanced.

	1911. 88 days.	1912. 79 days.	1912. 61 days.

Per ton of copper.....	3.44	3.24	2.65

During the last campaign, ores that had been concentrated by washing were treated, using 1700 tons of Wankie coke, which, produced from unwashed coal, contains much ash and sulphur. A washing plant for the coal is being erected at Wankie. Coke, delivered at the smelter, costs about $29 per ton. Until the quality of Wankie coal and firebricks made in Africa had been tested, construction of coke-ovens at the Lubumbashi works was postponed, but investigation proved them of good quality. A second furnace, of the same capacity as the one in operation, should be finished about February, but other plant will not be ready until June next. The briquetting plant will be ready about that time also. The erection of a new group of furnaces is under consideration. At the Star of the Congo, a plant for sorting and washing is well under way, and tests are to be made to get a better concentration by means of mechanical preparation. Discovery of coal of workable quality, near the Katanga railway, was recently reported.

In connection with the tin properties, the 'specialist engineer' will arrive from the Malay Peninsula with a selected staff about June, and will start work on the Kasonso deposits near Bukama. This engineer has had experience at Katanga, where, several years ago, he did the preliminary development and smelting at the Busanga tin mine.

Progress of the Katanga railway, 180 miles in length, is satisfactory. The traffic depends almost exclusively on the mining industry at Katanga. The whole system, which should be completed in March, will cover 290 miles, having taken four years in construction, which is fair work considering that there were difficulties with transport and labor, being 1600 miles from the port of Beira.

During the nine months ended September 30, 1912, net receipts from the Rhodesia-Katanga Junction Railway & Mineral Co., Ltd., were $130,000. Since June, 370 tons of copper was produced from the Kansanshi mine. On the Benguella railway the line to Huambo, 285 miles from Lobito, was opened in October 1911, and for the ten months ended October 1912 profits were $90,000, while estimates for the year 1913 show a profit of about $185,000.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

CONCENTRATE at the West End mill, at Tonopah, is now reconcentrated, the bulk being reduced and higher grade produced, effecting a saving in freight and smelter treatment charges. The sand from the concentrate so treated is pumped back to the mill circuit for further treatment.

MINE-RESCUE CARS are stationed at seven important points in the larger coal-fields of the United States. During the Bureau of Mines fiscal year ended June 30, 1912, 65,000 persons visited the safety cars and stations; 36,000 attended lectures; 10,000 took training in rescue work; and 1000 certificates were issued to miners.

DREDGE-MINING in New Zealand in 1911 produced gold worth $1,485,000 from 93 dredges, 31 of which paid $225,000 in dividends, and a total of 775 men were employed. Hydraulic mining produced $1,375,000 from 277 claims, which employed 2452 men. Of the dredges, 15 are working on the rivers and flats of the West Coast, and 78 in Otago and Southland in the South Island, while most of the hydraulic work is carried on in the West Coast districts.

PLASTICITY of clay, according to a recent hypothesis, is due to the presence of an organic aluminum compound. This assumption is claimed to explain satisfactorily all the established facts concerning the plasticity of clay. For example, it explains why only impure clays are plastic; why ignition destroys and levigation fails to restore plasticity; the industrial practice of weathering clay before use, and why the plasticity is reduced by bases, since the aluminunf organic compound is soluble in alkali.

BOTTLES containing liquid ammonia of 0.880 strength are apt to burst, or give a violent discharge of gas in hot climates. Before opening a bottle ought to be wrapped in a wet towel, or placed under a stream of cold water for a while. It is advisable to have convenient a weak solution of acetic acid, 10 drops in 100 c.c. of water, to use in case of alkalies getting in the eyes, the usual eye-bath being provided for that purpose. For acid in the eyes, a 1% solution of bicarbonate of soda, in distilled water, should be used.

IRON or steel articles can be made rustproof and at the same time given a good finish, by a process patented by W. Feuerhake, of Westphalia. The iron or steel goods are first electrogalvanized, and then lightly copper-plated from a copper cyanide solution. Then nickel plate is deposited on the copper, producing an excellent rustproof finish. The object of copper-plating is that, though nickel can be plated directly on zinc, it is unsatisfactory commercially, and it is always advisable to copper-plate the zinc first.

BOILER gauge-glass should have strength to resist pressure, insensitiveness to boiler fluctuations, and immunity to chemical action of steam or feed-water. Practically all gauge-glasses will stand 200 to 300 atmospheres pressure in the cold state. Heated up to boiler temperature and sprayed at regular periods, the strengths are considerably decreased and vary greatly; thus French glass will stand 6 atmospheres, English 7, Verbund-Robax 15, Durax 27, and Durobax 31 atmospheres. The makers of Durobax glass seem to have improved on its resistance to attack by steam and feed-water, as their gauge-glasses remain clear for a long time.

NICKEL used in the United States is chiefly imported from Canada. Large deposits are known to exist in Idaho, and an immense deposit of low-grade hydrous nickel-magnesium silicate occurs at Webster, North Carolina; but no economical method for the treatment of such material has yet been devised. A large part of the nickel output is now used in the form of monel metal, a nickel-copper alloy, so the expense of separating and purifying the nickel is obviated. Cobalt is chiefly derived from the silver-cobalt-nickel-arsenic ores of the Cobalt district of Ontario, and the price of the metal has greatly decreased since the discovery of the Cobalt district.

SPECIFICATIONS for the oil for mixing with concrete are given by the Office of Public Roads, U. S. A., for residual oils intended for waterproofing concrete according to L. W. Page's process. (1) The oil should have a specific gravity of 0.930 to 0.940 at 25°C. (2) At least 99.9% shall be soluble in carbon bisulphide at the ordinary temperature. (3) It shall contain 1.5 to 2.5% of bitumen insoluble in paraffin naphtha of 86°B. (4) It shall yield 2.5 to 4% of residual coke. (5) When 240 c.c. of the material is heated to 50°C. in an Engler viscosimeter and maintained at this temperature for at least 6 minutes, the first 100 c.c. which flows out shall show a viscosity of 40 to 45. (6) When 20 gm. of the material is heated to 163°C. for 5 hours in a cylindrical tin vessel, 2½ in. diameter by 1 in. high, the loss in weight shall not exceed 2 per cent.

DIESEL ENGINES of large size have become common in Europe; in Swiss electric stations Diesel-engine units of 2000 hp. are now in use, and it is said that the development of the large-size Diesel engine has been so successful that before long it will not be deemed extraordinary to develop 1000 hp. in one cylinder. One company of world-wide reputation is considering over 2000 hp. in the single cylinder type of Diesel engine. Engines of this type with four cylinders developing 1000 hp. power each can be made as light as the corresponding triple-expansion steam-engine. The weight of such engines compares favorably with that of the corresponding turbines and boilers. A 1000-hp. installation of this type weighed only 187 lb. per horse-power, as compared with 180 lb. for a steam turbine and boiler installation.

PERFECT german-silver castings have been obtained by adding 4 oz. of cupro-nickel-vanadium to the molten bath about 5 minutes before the heat is ready to pour. The cupro-nickel-vanadium, either granulated or broken in small pieces, is wrapped in a piece of paper and dropped in the molten metal, and when it becomes cherry-red is pushed below the surface and held there by an inverted cup-disk with a handle 4 ft. long. It is held near the bottom of the pot until it is completely absorbed by the charge. Then stir the pot with a pumping motion and allow the charge to remain quiet about 5 minutes, during which the vanadium effects the purification. The vanadium is not deleterious to the crucible. When the metal reaches a clear, limpid condition, shown by its greater mobility, the heat is ready to pour. When the metal is in perfect condition, flames of zinc oxide flare up at the sides.

FIREPROOFING of wood by impregnation under pressure is the most efficient method. As a general principle, each species of wood requires a different pressure for the necessary penetration, but the pressure remains constant for the same species, regardless of the dimensions of the piece to be impregnated. The penetration of the wood by a crystalloidal liquid is a function of the time. When displacement and penetration take place in a longitudinal sense, irrespective of pressure, the rapidity or duration of the injection will always be in direct relation to the length; for a given length and constant pressure, for the same species, the rapidity may, in certain cases, vary with the initial capillary speed, depending on the concentration of the injected solution. The species generally used are oak, mahogany, teak, ash, beech, gum, walnut, popular, fir, pitch pine, pine, and birch. The double phosphate of zinc and ammonia obtained by dissolving zinc hydroxide in ammonium hydroxide, and adding phosphoric acid, is superior to any other salt for impregnation, and is the only one that can be applied without inconvenience.

TABLE OF CONTENTS

EDITORIAL

STARTING of the Gumaus dredge of the Paracale district of the Philippines was appropriately celebrated by visitors from Manila.

JAPANESE copper production for 1912 is estimated at 65,000 tons. The Ashio mine retained first position with an output of 12,000 tons.

NINE million pounds of copper, equivalent to half the annual output of Tennessee, will be used this year by one American automobile factory.

PATENT has been issued to Mr. W. G. Whorf on 63 acres of coal land at Port Graham, Cook inlet, Alaska. This is notable as being the first patent granted for coal land in Alaska.

VENEZUELA has paid the last of the foreign debt resulting from international difficulties during the administration of President Cipriano Castro, and can now devote its revenue to internal improvement.

GUAYAQUIL is being studied by a United States Sanitary Commission headed by Colonel William C. Gorgas, and a safe and sanitary port is promised. With the opening of the Panama canal this will become a matter of first importance, and improvement of the port, following completion of the railway to Quito, will do wonders in opening Ecuador to modern industry.

SALE of controlling shares in the Golden Cycle Gold Mining Company at Cripple Creek to the Burris-Walker syndicate already controlling the El Paso mine, is announced in New York. It is said the consideration was $6,500,000 and that the shares are to be placed on the European market. The property includes the mine, the great mill at Colorado City, and a coal property near Colorado Springs.

MANY members of the American Institute of Mining Engineers, on receiving the invitation sent out by a number of well known engineers to join with them in subscribing $1000 each to wipe out the land debt of the Institute, will have concurred with the sentiments of the old colored man who was asked by a prosperous-looking white man whether he could change a $5 bill. His answer was, "No, sah, I cahn't change no five-dollar bill, but I thankee foh de compliment jest de same."

UNEARNED dividends of one per cent per month were paid by Messrs. A. L. Wisner and John J. Meyers, promoters now on trial in New York for using the mails to defraud, according to testimony given recently. It was shown that it cost $63,000

to mine $20,000 worth of ore at the Empire mine in Sierra county, and that 700,000 shares of stock had been sold for $205,000. The Kansas 'blue sky' law may not be perfect in form, but better protection of investors is certainly needed.

SEVEN years ago prompt wealth was promised investors in the Colorado Yule Marble Company. Now, with a total of $12,869,685 outstanding in stocks, bonds, and floating debts, stockholders are told that it is necessary to issue $2,500,000 worth of additional bonds to meet immediate needs. It takes more than marble to make a successful marble business.

MICHIGAN iron ore is to be subjected to a tonnage tax, remitted when iron is manufactured within the state, if a bill recently proposed be passed. The trouble with this plan is that Pennsylvania and Ohio might decide to tax coke or coal produced within their borders and remit the tax except in cases where the material was used in the manufacture of iron in a state maintaining a discriminatory tax on iron ore exported. The way to delightful complications is opened by the proposal.

EXPORTS to South America from the United States have increased from $38,000,000 in 1902 to $138,000,000 in 1912. So great a growth in the decade is encouraging and would be greater cause for congratulation if the total for the past year represented more than 10 per cent of the total exports to Europe. However, since exports to South America increased 300 per cent in the decade, while exports to Europe only increased 50 per cent, this disproportion is rapidly tending to disappear. So far our trade has been chiefly with Brazil, Argentina, and Uruguay, and the opening of the Panama canal should lead to a speedy growth of trade with the west coast of South America.

DUST in coal mines is a prolific source of explosions and in metal mines is the leading cause of miners' phthisis. In South Africa determined efforts have been made to lessen the danger of the latter by regulation of the use of small air-drills. In Nevada a bill has been introduced in the state legislature prohibiting the use of machine drills save in connection with water sprays or other efficient dust reducing apparatus. Since there are several means that may be employed, this is fair to all manufacturers, and without passing on the wording of the particular bill mentioned, we but express general opinion in saying that the movement to protect the health of miners deserves hearty support.

NOMINATION of Mr. C. F. Rand for president of the American Institute of Mining Engineers assures to the latter the services of an especially capable and active executive. Mr. Rand's success as president of the Spanish American Iron Company, his indefatigable industry, large public spirit, and charming personality, combine to peculiarly fit him for the position. Mr. Bradley Stoughton, who is the official candidate for secretary, is an experienced and capable engineer not so well known in the West as his deserts warrant, since he has worked mainly in the East and on the metallurgy of iron and steel. Mr. Rand and Mr. Stoughton, with a good board of directors, will assure satisfactory conduct of the business of the Institute.

FORMATION of the American Mine Safety Association, having for its purpose the conservation of the lives and health of the mine and a reduction of property loss due to explosions or fires in mines, is announced. This is one of the results of the interest in the subject aroused by the excellent work of the United States Bureau of Mines, and it is appropriate that Mr. H. M. Wilson of the Bureau should be chairman of the executive committee. Membership is open to individuals and firms and those interested are invited to correspond with Mr. Wilson, care United States Bureau of Mines, Pittsburg, Pennsylvania.

EDITORIAL comment performs its best service when it stimulates such thoughtful contributions to our discussion columns as that by Mr. Herbert Lang upon the use of oil as fuel in the blast-furnace. Radical departures from ordinary practice, such as this, develop unexpected difficulties, as our correspondent cites. For the reasons given, it seems probable that oil will never be able to perform the double function as a reducing agent and as a source of heat which coke adequately fulfils. The combustion period of the coke is comparatively protracted because of its slow descent with the smelting column, while the combustion period of the liquid fuel is the brief interval between its ignition at the tuyere and its escape from the zone of combustion. With the coke there is ample opportunity to secure a powerful reducing action in the charge and complete combustion in the zone of fusion, while with liquid fuel the opportunity is so limited as to present marked difficulties. Nevertheless there would appear to be a distinct field for smelting with liquid fuel, and it is to be hoped that other metallurgists will follow the lead of Messrs. Lang, Wallace Dow, Thomas Kiddie, and J. W. Nesmith in its experimental development.

DISCUSSION of the factors governing the choice of an electric motor for hoisting service, as given by Mr. H. A. Russell in this issue, will be both of interest and service to many of our readers. The illustration of a motor-generator set is especially interesting as a sequel to our editorial comment, in the issue of January 25, upon electric hoisting problems, in which it was suggested that an exciter directly connected to the drum-shaft of the hoist would render the electric brake independent of interruptions in the power supply and solve the problem which is troubling South African engineers. It has since been brought to our attention that this result may be better attained by placing the exciter upon the shaft of the fly-wheel of the motor-generator set, as shown in one illustration in Mr. Russell's article. With this arrangement the electric brake will not lose is effectiveness until the fly-wheel has come to a stop; a considerable period in which there is ample opportunity to complete the trip with the cage or skip. A hoist of

this character, built by the Wellman-Seaver-Morgan and General Electric companies is now in successful operation at the Duluth shaft of the Cananea Consolidated Copper Company, and others are in process of construction.

AMONG excellent recommendations made by Mr. Walter E. Clark in his annual report as Governor of Alaska, is one to the effect that holders of mineral claims be allowed to pay in lieu of assessment work $100 per claim per year into a fund for highway and bridge construction. This plan has been followed in Yukon territory with very satisfactory results. It often happens in Alaska that the expense of doing assessment work is much less than that required to send men to the claims to do the work. In such cases it would be to the advantage of the claim owners to pay the cash instead. There is nothing Alaska needs more than roads, and it would certainly seem wise to divert to their building money now largely wasted in assessment work.

Regulating Dredging

Gold dredging is attacked in a bill recently introduced in the California legislature. The bill starts with the declaration that cultivation of the soil is an ordinary use necessary for future subsistence, livelihood, and prosperity of the people, and that use of the soil for dredging purposes is an extraordinary and uncommon use, and provides that any person, firm, or corporation intending to mine soil for gold or other precious metal must make a written application to the State Water Commission for a permit. The application must state the situation of the proposed dredging area, the nature of the soil, whether it has been or is under cultivation, and, if so, the nature of crops and approximate value of the last crop; also whether, in the opinion of the applicant, said soil is more valuable for agricultural than for dredging purposes, and whether it can be restored, after dredging operations, for agricultural purposes equal to its condition at the time of filing. The commission must then examine the soil within thirty and hold a hearing within sixty days. Within thirty days after the hearing it must act on the application, denying a permit if the soil is found more valuable for agriculture. In determining the relative value the commission shall not be limited to a consideration of the value of the annual production of the soil, but may take into consideration the future and natural continued use for agricultural purposes. If it appears to the commission that the soil is more valuable for agriculture, but can be restored after dredging, the commission may grant the application and issue a license, containing as a condition that the soil be restored. It is proposed to make violation of the act a misdemeanor, punishable by $5000 fine or imprisonment not exceeding one year, and individuals acting for corporations are made personally liable. Advocates of the bill declare that dredging companies cannot consistently oppose it, because they have made the claim that dredging is confined to worthless lands, or lands that can be restored. While it is true that little land of agricultural value has been destroyed by dredging, the companies will naturally prefer not to have to justify to an outside and possibly hostile commission, their use of land before beginning work. It will greatly complicate the matter of buying dredging land, since it will be necessary to prospect it before submitting it to the commission and, if by chance the decision after prospecting is a close one, there may be no opportunity to recover the money already invested. It is also worth remembering that interest on the money won from an acre of land by dredging is often many times in excess of the value of any crop that could be annually harvested.

American Institute Election

The world over, the American Institute of Mining Engineers occupies a more conspicuous position than any other of our technical societies. It is exactly because this is true that its affairs must be conducted on the highest possible plane. Our readers are already familiar with the fact that the recent business conduct of the Institute has received unfavorable comment. This is directed at policies and methods, and only at individuals to the extent that they defend and justify the things criticised. We have frankly expressed our opinion that a thoroughgoing change is necessary and that this necessarily involves changes in personnel. In this we but coincide with the opinion of the nominating committee and many of the best friends of the Institute most familiar with its affairs. The matter is before the members and there is abundant room for honest difference of opinion. For our part we do not believe that an officer of the Institute should by force of his position make money out of its members, and we do not consider it proper to reëlect the beneficiary of such a system. To our way of thinking this is not a case where one may properly waive his judgment because of personal friendship or appreciation of excellent work done in the past. The issue is clear, though the method of voting has become confused because of changes already made in the articles of incorporation and impending in the constitution and by-laws of the Institute. Those who wish to vote for the new order should proceed as follows:

1. Make out and forward the proxy drawn in favor of Messrs. A. R. Ledoux and James Douglas, indicating a preference for the new constitution and the new order of business.

2. Vote ballot A, in person or forward it with the proxy drawn in favor of Messrs. W. R. Ingalls and W. H. Nichols, Jr.

3. Vote ballot C, which requires no proxy, but which will be invalid unless only two directors each for the one and the two-year terms be voted for, with five for the three-year term.

4. Make out and forward the proxy asked by Messrs. C. R. Corning and G. C. Stone. Probably, as those gentlemen state, the proxy will never be officially counted, but it will have an important moral effect.

Remember that a new proxy supersedes one already on file and that the date of the election is February 18. Vote, and vote early.

Electric Hoists for Mine Service

By H. A. Russell

*The use of electricity in mining is only limited by the available supply and cost of current, whether produced by the mining operator or bought from a power company. The most potent factor in the growth of a community is transportation. The country dependent upon burros can never progress like one gridironed with steel and macadam roads. And so it is with mining, where the hoist means transportation, and may be anything from a windlass to an up-to-date ore carrier. A hoist may spell success or failure for a mine, and always plays an important part in the operating expenses.

Early Use of the Hoist

The hoist has been the last thing to consider in electricity as applied to mining, because men naturally do those things first which are easiest. The miner first lighted the surface plant and mill with electricity and then applied motors to the stamps, concentrators, and other machinery, so that in many cases everything about the mine was electrical except the hoist, leaving this to be operated by steam, or in some cases water-power. One reason for this was the miner's prejudice against an innovation that might be attended with some risk. He did not wish to risk his life on an unseen power which might fail him. The gradual and almost universal application of electricity, however, has brushed aside this prejudice so that the electric hoist is no longer considered a machine of greater hazard than the long-used steam hoisting engine.

Direct and Alternating Current

It is sometimes asked, in applying electricity, whether it should be direct or alternating current, and a brief comparison of the two may be in order. Direct current is best for all operations that entail much speed control, as the speed can be controlled by a change in voltage or by a change of resistance in either the revolving element (the armature), or the stationary element (the field); whereas a change in voltage in an alternating current motor does not affect the speed. The variable-speed direct-current motor therefore has more possibilities for hoisting than the alternating, but it has its drawbacks for mining work in being a low-voltage machine, and low-voltage direct current is not adaptable to long distance transmission. A current of electricity flowing through a conductor will induce an equal current in an opposite direction in a conductor placed near it, at the moment of starting and stopping. This principle is applied in a transformer which consists of two sets of coils, one carrying the primary current and the other carrying the induced current, and this induction principle is continuous, as the alternating current is a continuation of starts and stops. This enables manipulation of the voltage at will. Current is generated at a low voltage easy to handle, stepped-up by transformers to high voltage, enabling transmission over long distances with small conductors and small losses, and stepped down by transformers again to safe voltages easy to handle for final use. With direct current the ultimate voltage is limited to comparatively small values and transformation can only be done by motor-generators, which are expensive and entail heavy losses. It is therefore necessary to use only alternating current where long distance transmission is general, as in the Western states. For this reason the only case where direct current is practicable is for large hoists, where it is sometimes used, as will be explained later.

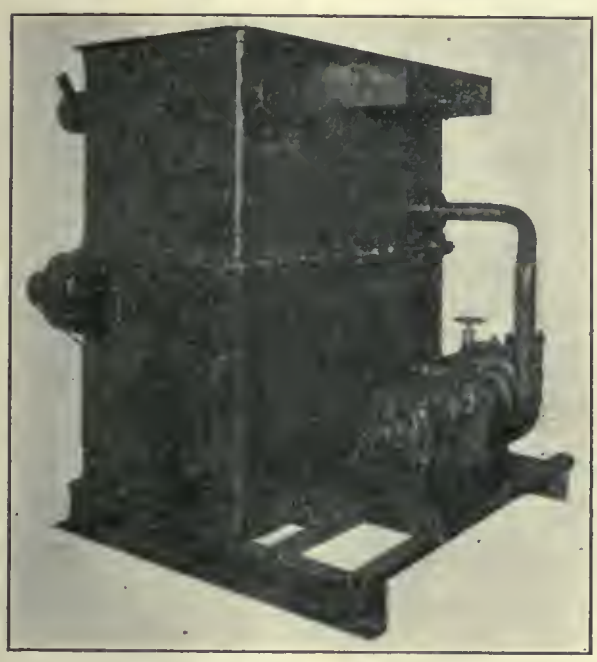
Relations Between Miner, Power Company, and Manufacturer

The hoist motor is the most difficult problem about a mine for the electrical engineer to solve, as it calls for heavy strains for short periods, delicate control of speed over wide ranges, and must be at all times reliable. Aside from the heavy strains which demand mechanical strength, the prime mover back of it must be of sufficient capacity and under such automatic control that the starting of the hoist will not put the rest of the plant 'out of business.' With a generator of 200-hp. capacity furnishing power half of which is used by a hoist, the starting of the hoist would stall the water-wheel and shut down the entire electric plant. The generating plant must be large enough to stand the heavy starting strain, and the water-wheel control must be able to keep up speed and, consequently, voltage when the heavy hoist load comes on. In the early application of electricity to mining the electric plants were scattered about in comparatively small units. The generators were much smaller than at present used, and the plants themselves were comparatively small. This made it undesirable for the power companies to take on a hoisting load which called for high power for short periods and a consequent disturbance of the system. When the hoist load is fed by large transmission systems the power companies still had to face this same difficulty in delivering current to a mine. While the hoisting load may not shut down the power company's plant, it can greatly disturb the other power users in the vicinity by dimming lights and throwing out circuit breakers. It is for this reason that the power company is obliged to keep the so-called peak load within certain bounds.

Another point more important to the power company than to the miner is the comparatively small revenue derived from hoisting. A stamp-mill takes continuous power at a fixed load for 24 hours in the day and the power company has an investment in apparatus every dollar of which is earning revenue. A hoist, on the other hand, is taking 100% more power during the period of acceleration than when it comes up to speed and is then shut off entirely.

*A paper delivered before the California Miners' Association, December 1912.

Generally speaking, a hoist is not earning dividends for the power company's investment more than one-third of the time and during this time the average load will not be over half the maximum demand. For these reasons the electric hoist has not advanced as rapidly as other applications of electricity to mining, but the power companies have had such rapid growth, their plants have grown to such enormous proportions, and their lines have so grid-ironed the mountains, as well as the valley, that they are now in position to offer current at rates profitable to themselves as well as the miner. The problem of the manufacturer is to supply a hoisting motor that will do all that the miner requires and in a way satisfactory to the power company. It is a matter where three parties are concerned and the



LIQUID RHEOSTAT FOR MINE HOISTS.

manufacturer must call upon the miner to give him all the data possible in selecting a motor that will be satisfactory to all.

Selection of a Motor

A hoisting motor must operate over a wide range of load, in fact, from zero to 50 or even 100% over its rated capacity for short periods.

Its efficiency characteristics must be comparatively good over this range. In other words, it must have a flat efficiency curve.

It must be reversible.

It must be of comparatively low speed for connection to the hoist-drum by means of gearing or rope drive in the larger sizes.

It must have high starting torque to enable it to start the load from a state of rest.

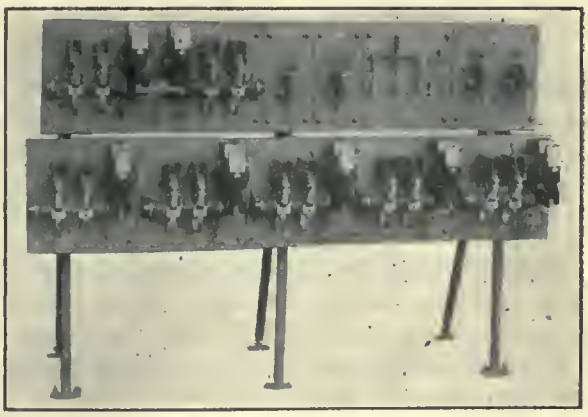
It must have speed control, from zero to full speed in fine gradations.

Being properly designed electrically it must have the mechanical design to withstand the various loads imposed upon it.

For constant-speed operation such as a stamp-mill or a rock breaker, it is a simple matter to calculate the proper horse-power to do the work. It is not so simple with a hoist. In addition to knowing the rope speed and the load the designer must know the period of acceleration, retardation, and rest. A motor may be designed for very heavy torque at starting and a short period of constant speed which would be exactly suited to a certain hoisting operation. Say the rating of such a motor is 100 hp., this same motor running under much smaller load, but running continuously, would not be at all satisfactory and would likely burn out in a short time. It is like a high-spirited road horse that is good for a burst of speed for a short distance, but would wear himself out if hitched to a heavy load.

MOTOR-GENERATOR HOISTING SET.

The manufacturer finds it very hard to establish standards where varying conditions are to be met, but in the case of hoisting motors they have tried to fix two general standards. One is a hoisting motor for intermittent duty where the load comes on and off frequently, requiring very little beyond its starting capacity. Such a motor is found in the



CONTACTOR PANEL.

usual mining hoists. Another is the continuous-duty hoist that must start its load, be under control, and then work for long periods at a fixed speed; such a motor is found in the digger on gold dredges. The miner will thus see why it is necessary for the manufacturer to know the conditions under which he is to operate and why it is necessary for him to furnish the data the manufacturer requires. The bare statement that a 100-hp. motor is wanted for a hoist is vague and misleading. What kind of a horse shall it be—a roadster or a draft-horse? There is as much energy and value in one as the other, but each has its place.

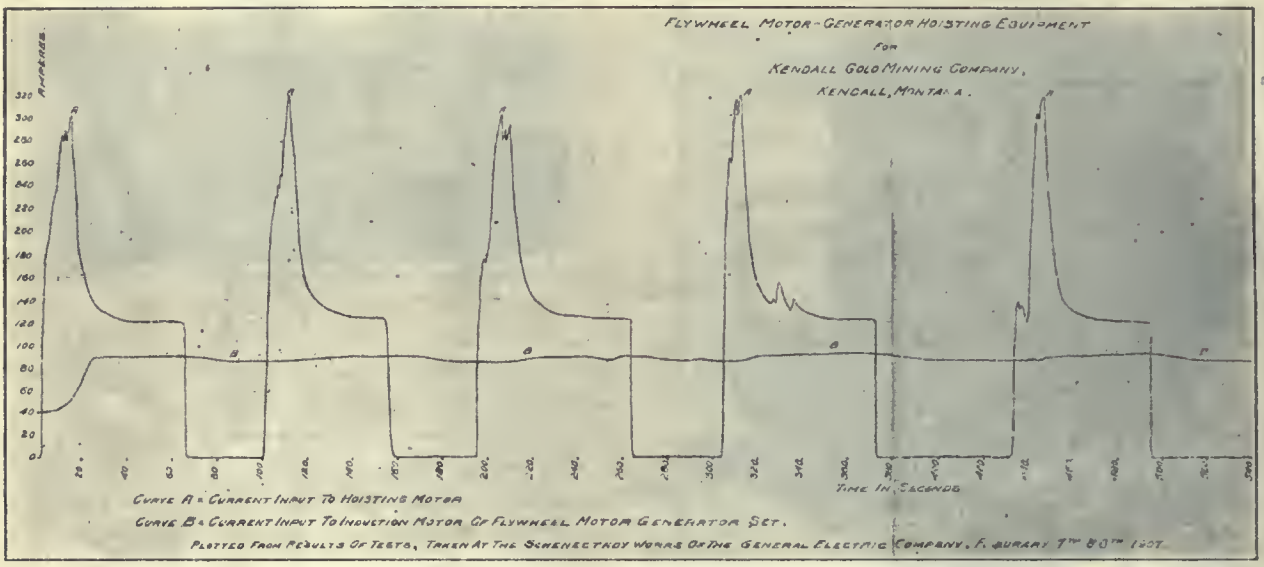
In taking up hoisting question, the following data

are of utmost importanee: Ultimate depth; angle of shaft; condition of track; weight of ore; weight of skip; size of rope (whether or not tail rope is used); speed of hoist with ore; speed of hoist with men; number of trips per hour; whether single or double drum (make of hoist); whether to operate balanced or unbalanced; when working balanced, is it necessary in case of emergency to operate unbalanced; number of seeonds required to accelerate; souree of power; eyele of duty (time to load, time to unload); if necessary to operate at reduced speed (sueh as for inspection and timbering), how long will such period last?

With the universal use of electrically-operated street-cars, similar data is furnished by the railway operators, so that manufacturers feel perfectly se-

Controlling Apparatus

After the motor, the control is the important factor in a hoisting outfit. The control is under constant operation, making and breaking contacts, and should be designed with sufficient carrying capacity to withstand this excessive use. With motors up to 150 hp. there is no difficulty in designing a simple drum controller that will satisfactorily take care of the work. Beyond 150 hp., however, the current begins to be unmanageable, and burning of contacts becomes a souree of expense and delay. It then beeomes necessary to use the controller as an auxiliary device, whieh makes and breaks eontact through contactors which are so arranged that the arcing is easily extinguished and the heavy eurrent does not enter into the controller and thereby dam-



POWER INPUT, WITH AND WITHOUT MOTOR-GENERATOR SET.

eure in guaranteeing their operation. The same security should be felt by both the manufacturer and the miner when suffieient data are furnished and the motor is designed for the particular work in hand.

Horse-Power Needed

The horse-power that is to be considered in selecting a hoist can best be illustrated by an example. The maker is furnished with the data necessary as to depth of shaft, speed, etc., and finds that the hoist when working unbalanced will require 335 hp. for the first six seconds during aeceleration, then the load immediately drops to 248 hp. at the end of eight seconds; from this point on the load gradually drops, due to the winding of the rope until it reaches 176 hp. after 160 seconds. Here the cycle is nothing, 325 hp., 248 hp., 176 hp., and nothing again. What should be the size of the motor to take care of this hoist? With this same hoist working balanced, the starting horse-power jumped to 298, immediately dropped to 189, then, due to the winding in of the rope, gradually dropped off to 54 hp. With the necessary data in hand, the manufacturer was able to design a motor, or rather select one, of a line of standards rated at 225 hp. intermittent, that he could guarantee to successfully perform the work.

age it. On the contrary, it is properly taken care of without injury, through the contactors.

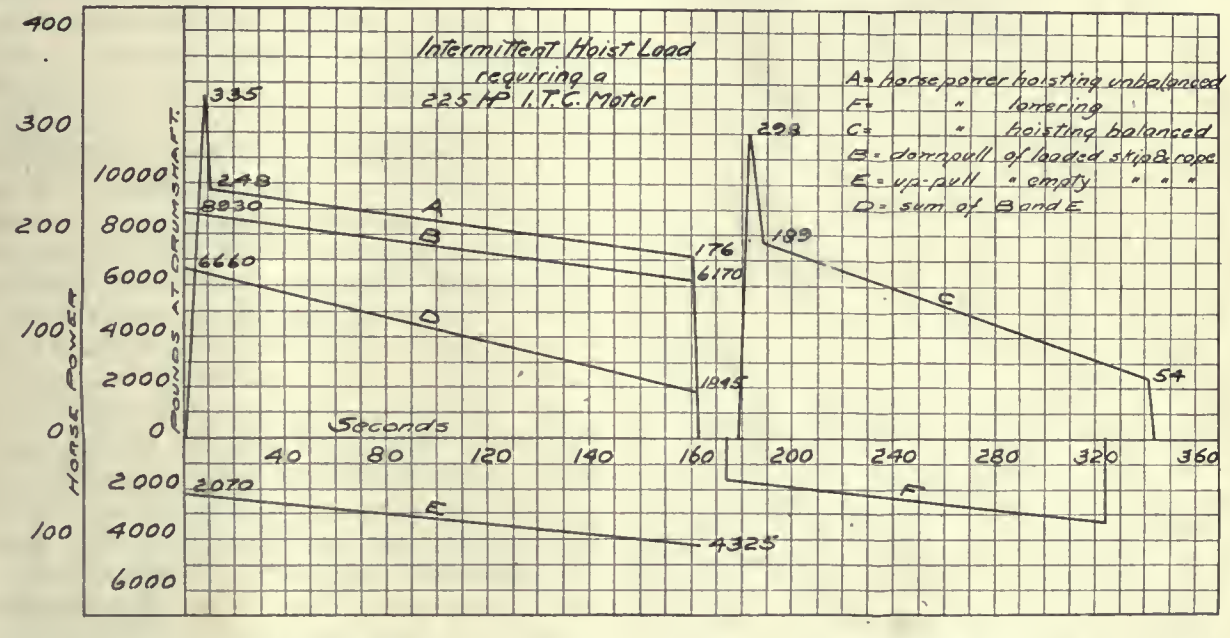
The contactor has another important safety feature. With the straight-drum controller using small currents, it is a relatively small matter whether the current be thrown on slowly or all at once. With heavy eurrent, however, and unwise use of the controller, it would result in serious damage and the contactor system is designed to limit the flow of current that ean take place at any one time. The operator might throw his controller around to the full-speed position, but the contactors would automatically come into play, one after another, without allowing excessive inrush of current at any point. Contactor-control panels are designed for motors of 150 hp. up to over 1000 hp. There is another method of control which lends itself to finer graduation than the contactor-panel, and it is therefore sometimes better, but the cost is too high to offset its advantages except in very large hoists. This is the liquid control. The resistance, instead of being cast-iron grids, is a liquid used in a tank which is water-cooled. This makes it easy to dissipate its heat through radiation by the circulation of water. These controls have been used extensively in South Africa on work where long periods of reduced speed are desired and with motors of 400 hp. or over. The system has many advantages.

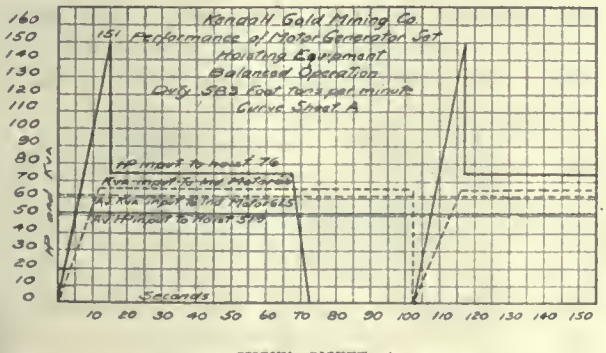
Peak Load

The power company objects to excessive loads, and where the power rate is based upon peak load it becomes necessary for the manufacturer and miner to get together and keep down that peak. This may be done in a degree by balancing the load in a double-compartment shaft. It has been done in some cases with a tail-rope, but this is not practicable in developing a mine, where the lower level is always changing. It may be done through a storage-battery whereby the battery may be stored under a steady load 24 hours per day and drawn upon at will by the hoist. This involves the installation of a motor-generator set and a storage-battery, an expensive outlay.

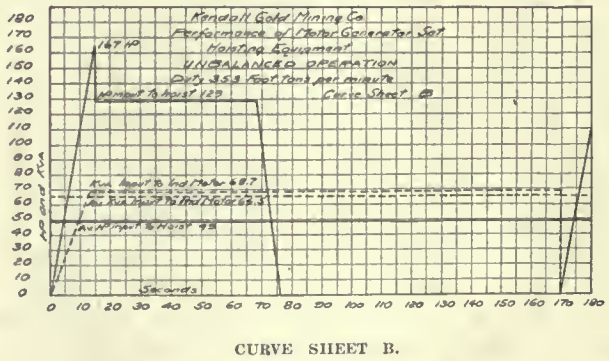
Another plan is the fly-wheel motor-generator set. This system, like the storage-battery system, involves the use of a direct-current motor on the hoist and is one of the cases where ease of regulation makes it desirable to use direct current. The system consists of an induction motor, which receives alternating current, two or three-phase from the power company, direct-connected to a separately-excited generator, and a heavy fly-wheel, all on the same shaft, as shown in the illustration. The hoist itself, as stated, is operated by a direct-current motor. The motor of the motor-generator set is kept running all the time. When the current is thrown on by an automatic control device, as shown in the illustration, the speed of the system is reduced. As soon as the speed drops, the fly-wheel gives up its energy to the generator. When the load goes off, this action is reversed and the fly-wheel then absorbs the power from the system. In this way the excessive peak is taken off and intermittent hoisting is accomplished by a steady drain of power.

The curves given below graphically show the operation of the system. The ragged uneven curve shows the power as it is actually taken by the direct-current motor, and represents the varying load of the hoist. It has sharp peaks and wide valleys. Curve *A* shows the input to the induction motor in comparison to the input to the direct-current motor.





CURVE SHEET A.



CURVE SHEET B.

It shows that the input to the induction motor never runs above 66 kva., or 5 kva. more than the average, which can hardly be called a peak. On the other hand, the input to the hoist is 151 hp., with an average horse-power of 51.9. If the miner had to pay on the basis of the peak load in this case, he would pay nearly three times as much for his current as he would with the motor-generator set. Between the time when the hoist is thrown off and starts up again, the input to the induction motor continues and the fly-wheel is storing energy for the next operation.

Curve *B* is similar to curve *A*, except it is not unbalanced operation, and the curves show that when the hoist load comes on, that of the induction motor goes off, and *vice versa*, thus evening up the drain of curren from the line. In the set from which they were taken, that of the Kendall Gold Mining

Co., Kendall, Montana, the motor is 75 hp., direct-connected to a 120-hp. generator.

Extent of Electric Hoisting

The field for electric hoisting in the West is a large one, and worthy of careful consideration. The power company is prepared to give good service, the manufacturer is ready to furnish reliable apparatus guaranteed to do the work, and the miner can contract with both of them at terms which will show a good return on his investment and a consequent decrease in his operating expenses. It seems like extravagance to throw out a perfectly good steam-engine, that has paid for itself over and over, for the sake of applying electricity. Yet we constantly see engines disconnected or taken away from the hoisting drums, and motors put in their place. It has paid to do it, or it would not have been done. How much better would it have paid had the motor been installed in the first place. In a new venture the power company will run lines to furnish the current, first for a prospecting hoist, and later for the large hoist suitable for heavy work. Where the power-lines are too far removed to economically reach the mine, an independent power-supply can often be developed. The miner, the power company, and the manufacturer are mutually interested in mining development. In the case of new power development touching on Government reserves, perhaps Uncle Sam had better be added to the trinity. This is as it should be, for the harnessing of water-power stands for true conservation. Water-power is unfailing, yet it saves the timber, coal, and oil, which do fail. The Comstock has been reopened by means of electricity for hoisting water, timbers, men, and some ore, and but for electricity this work would never have been resumed. On the Mother Lode a number of hoists have shown good results with electric power. Some of the power companies are supplying current for hoisting work at 1½c. per kilowatt-hour, and less, depending upon the size of the hoist and voltage conditions. This would amount to about $8 per month per continuous horse-power. With current about this figure, mines on the Mother Lode have put in electric motors, replacing steam, with fuel-oil at about $1.75 per barrel, and by so doing have cut the power bill in two.

Coal production from the Honan, China, mines of the Pekin Syndicate, Ltd., for 1912 is estimated at 450,000 to 500,000 tons. The company has had many difficulties to contend with, and no dividends have been paid during the year. Measures are being taken to engage in other forms of profitable business than mining, and the company has already invested $4,000,000 in 5% Honan railway bonds.

Zinc smelters in operation in Belgium in 1911 numbered 13, and produced 198,230 metric tons of spelter, valued at $23,933,659, a large increase over preceding years. There are 6 lead-silver smelting plants, which treated 860 tons of Belgium ore, and 58,580 tons of foreign ore, yielding 96,025 tons of lead and silver valued at $5,150,928.

Placer Gold Dredging and Washing in Bolivia

In addition to the rubber and other jungle products, all the rivers emptying into the Amazon carry gold. Many of the Indians earn their living entirely by washing the gravels from those rivers. The surface gravel is quite rich in gold, where the stones have formed a kind of riffle to catch the grains. By removing those stones and washing up the gravel for a foot in depth, the Indians often make $5 (gold) per day, and some white men make a great deal more. As pointed out, the surface gravels are rich in gold, and this has been the means of inducing an English company to take up many hundred pertenencias of dredging claims on the Kaka river. This company was first formed with a capital of £100,000. After less than two years' work, and before the dredge was working, it went into liquidation and was reorganized with even more capital. It had hardly started work when it again went into liquidation, and was again reorganized with a further capital of £100,000. After being 'bust' for the third time, someone connected with the company thought it would be wise to test the gravel to be found below. Accordingly, an engineer was hired for the first time to test the gravel. He condemned the whole scheme. This was an English company and English capital, with a properly constituted board of directors and a 'real live Lord' for a chairman; must have a Lord for a chairman in order to preserve a frigid atmosphere, in case any shareholders ask impertinent questions, and at the same time give the shareholders the 'glassy eye.' After five years' work (Heaven knows what they were doing all this time) the dredge was started, worked 360 hours and recovered 25 oz. of gold, nearly £100,000 having been spent in the vain effort.

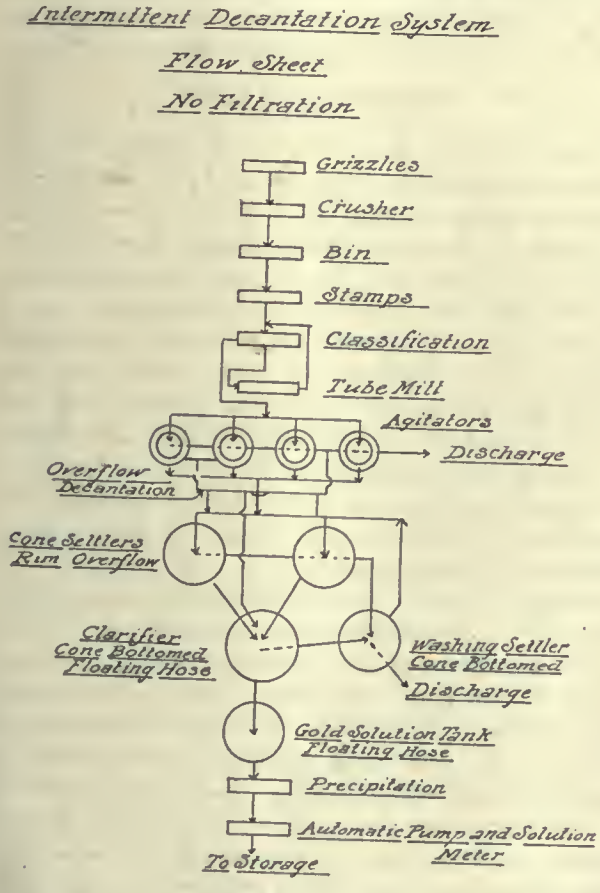
After this company had entirely failed, an old Irish prospector came along, tested the ground along the Kaka river, and decided to work it. He made a rocker out of an old gin-box, and with it and his two hands worked a month and took more gold out of the gravel than the properly organized English company which had spent in a dignified manner, with a large staff, nearly £100,000 of the shareholders' cash. This prospector might have been there yet, but after he had worked a few days he got on a wild 'jamboree' and, while loaded down with 'bugjuice,' danced Irish reels along the Playas and 'whooped it up' in such a manner that he scared the Indians, who used to transport him on the *balsas*, until they thought he was crazy and would not come near him. In vain he tried to get them to come to him in confidence. It is true they came, but always brought some peace offering, like the leg of a pig, some yams, or other food, which is the custom with the Indians thereabouts when approaching somebody of whom they are afraid. There are many prospectors of this hardy type who pass through this region after having followed nearly every gold rush for the past thirty years, and finally they drift down the river, ever onward, until they fill a place marked with a little wooden cross somewhere between here and the Atlantic.—*West Coast Leader.*

The Intermittent System of Cyanidation

By L. P. Hills

*The popularity of the continuous system of direct cyanidation is, I believe, an unfair verdict against the intermittent system. The former undoubtedly sprang from the difficulties encountered in the latter in promptly effecting a condition of suspension in the charge to be agitated, clogging of pipes, etc. All of these difficulties can be wholly obviated at present, one means being by the use of the agitator hereinafter described.

Theoretically, the charge system surpasses the continuous. The latter is, by its very nature, inefficient. Assume a series of 100-ton tanks, with a flow of 10 tons per hour. Consider the efflux from the first tank for any given hour. That 10-ton portion is composed of, approximately:



0.909 tons of the influx of the given hour
0.825 tons of the first preceding hour
0.751 tons of the second preceding hour
0.683 tons of the third preceding hour
0.621 tons of the fourth preceding hour
0.565 tons of the fifth preceding hour
0.513 tons of the sixth preceding hour
0.466 tons of the seventh preceding hour
0.424 tons of the eighth preceding hour
0.386 tons of the ninth preceding hour
0.351 tons of the tenth preceding hour

the remaining 3½ tons in diminishing portions back to the initial inflowing 10 tons. The great bulk of the pulp receives exceedingly long treatment, the time of treatment of different portions varying between wide limits. Also the heavier and coarser particles make the most rapid transit through the series; thus that portion requiring the longer treatment gets the shorter treatment. The ideal system, wherein the pulp receives the exact treatment required to perfect extraction, can be closely approximated in the intermittent system.

The accompanying flow-sheet illustrates an intermittent decantation system for which the following merits can be reasonably claimed: Simplicity, cheapness of installation, economy of power and labor, low maintenance cost, flexibility of operation.

The agitator is the chief feature of this system, and insures reliability of operation. It is a modification of the Pachuca, the central fixed column being surrounded by a vertically adjustable column of a few inches greater diameter. This outer column, by means of a screw at the top of the tank, may be moved from a position where the lower end of the column is in contact with the sides of the cone, to any predetermined point above that, the upper extremity of the column always being below the surface of the solution. During the time agitation is suspended and settling is taking place the outer column is in its lowest position, thus excluding the pulp from settling around the inner column and air-jet. To start agitation, turn the air on, which will institute circulation of solution down between the two columns and up through the central column, whereupon the outer column is raised, allowing the pulp to enter into the circulation. This agitator has been subjected to all kinds of tests and never failed to get the pulp into a condition of suspension and without the aid of additional air.

In the system under consideration, a thickener to precede the agitators is not necessary. The agitator is provided with a baffle which gives a circumferential quiet zone when pulp is being run in and when agitation is taking place, the overflow going to cone settlers. When a charge is sufficiently thickened in the agitator, the pulp is switched to another agitator, and agitation started in the charged tank. During agitation, barren solution may be run in to lessen the gold contents and also to vitalize the solution in the tank.

The extraction being completed, the outer column is screwed down, agitation suspended, pulp settled, solution decanted, and washes repeated as many times as is advisable, depending on the richnes of the ore. The settlings from settlers and clarifier are drawn off intermittently to washing settler, or agitator, and washed.

This system permits operating so that the finer pulp, in which the extraction is rapid, receives the short treatment and the heavier and coarser pulp receives longer treatment.

*From *Colorado School of Mines Magazine.*

Exports of iron ore from Chinnampo, Korea, to Japan are at the rate of 150,000 tons per year. This ore is secured from the Chai-lyong, Anak, and Eunyul mines. Exports of coal from the anthracite mines at Pingyang amounted to 100,000 tons, all going to the naval briquetting plant near Tokugama, near Shimonoseki.

Methods of Teaching Assaying

By D. C. Livingston

The ideal engineering course is one that instils the fundamental scientific principles that underlie every phase of engineering work, and also emphasizes these principles in their practical application and relation to modern engineering projects. In addition to this, the technical school should give to the student who has devoted four years of his life sufficient training in one or more branches of his profession to enable him to creditably fill the positions which he most likely will be called upon to occupy on graduating.

The mining graduate is most likely to be called upon to do either one or all of the following things: surveying, drafting, assaying, and analytical work, or possibly the testing of machines or processes; this last being a somewhat newer line in the direction of efficiency engineering that seems to contain possibilities for the graduate engineer. A number, of course, will obtain work underground until something more to their liking develops, but if statistics were available of the first technical work done by mining graduates, it would be safe to say that the list given would cover ninety out of a hundred. The mining student on graduating should be able to go into a mine assay-office and do the work required without any further instruction, and he should be also capable of making a complete survey of a mine and drawing a set of maps, if called upon to do so.

Defective Teaching

In most of the best engineering schools in this country, field practice in surveying is acquired during a summer school under conditions similar to actual practice, and an intelligent man, on completing such a course, should be quite capable of creditably filling a position as instrument man on a survey party or as mine surveyor, without further preparation. The same cannot be said about courses in fire-assaying, as given in most mining schools, and the unpractical method of teaching fire-assaying which is generally in vogue has often been mentioned in the technical press. The mining graduate is generally incapable of handling the amount of work that is usually required in a mine or smelter assay-office without first learning how to systematize his work. It has occasionally happened that a young assayer has thrown up his first job in despair, and those who have not left have usually been forced to work many unnecessary hours through lack of proper preparation, until they had learned how by experience.

The object of this article is to describe a method of teaching fire-assaying recently adopted at the University of Idaho, which was designed with the object of giving the student a thorough knowledge of the underlying principles and in addition capacity for handling a large amount of work and obtaining accurate results. Though it is fully realized that this course is by no means perfect, yet if its description does no more than bring in one useful suggestion for improvement, it will have fulfilled its object.

The course as given takes two afternoons per week, or its equivalent, throughout the whole of the junior year, and consists of four divisions: (1) the acquisition of a knowledge of the principles and reactions of the processes involved; (2) the acquisition of accuracy in the work; (3) special methods for difficult ores and metallurgical products, assay of bullions, ores containing metallic particles, etc.; (4) acquisition of speed and accuracy combined, and the handling of a large amount of work.

General Plan of Course

Acquisition of the principles is accomplished by laboratory practice, accompanied by explanatory lectures and reading from text-books. Fulton's 'Manual of Assaying' being the one used. In the laboratory work, after he has made sufficient cupels to last the semester, the student first runs a set of experiments to determine the reducing power of the common reducing agents like flour, argol, coal, sulphur, and pyrite ore, with both silicious and non-silicious charges. He then determines the oxidizing power of nitre against several reducing agents in charges similar to the first. This work gives him practice in handling his furnace and in making fusions. He then calculates a series of lead-soda-silicate slags for: (1) a high-grade silicious silver ore; (2) a high-grade silver sulphide ore. In the first case the slag is calculated to range between a tri-silicate and a sub-silicate, and in the second, by varying the amounts of silica as well as the other reagents the slag is made to range between a bi-silicate and an oxide slag. The physical effect of various slags is noted, and the actual effect is determined by cupelling the resulting lead button and weighing the silver. This brings out the reasons for using certain reagents, and both the theoretical and practical limits of the amounts to be used in these two classes of ore.

Necessity for care in sampling is brought out by each student taking a series of samples from a 'spotty' silver ore, which is reduced in size after taking each sample by further grinding and re-sampling. When several students work on the same ore their results will differ widely on the coarse samples, but should agree on the final grinding if this is fine enough and the sampling conducted carefully. The size of lead button which will bring down the maximum of the precious metals is also determined by experiment, using a fairly high-grade ore, by reducing a series of buttons of different weights and plotting the results obtained by a number of the students on the same ore. This work should take from 15 to 20 afternoons to finish properly, or approximately half of an average semester, when two

afternoons per week constitute the course. One of the most important things is accustoming the student from the start to handle as many as five or six duplicate determinations at the same time. This will tend to make him systematic in his work in order to keep his samples from getting mixed. The student is never allowed to mark his crucibles, but is made to run them in rotation as he would have to in practice. Accuracy is demanded in this part of the course, and all duplicate assays are required to check or be repeated.

Training in Accuracy

Acquisition of accuracy, by practice in crucible work, scorification, and fire-assay for lead, is accomplished, as in all other institutions, by handing out to the student carefully checked samples. These are either pulp or samples of 20 lb. in weight or thereabout, ground through 20-mesh. The large samples the student samples and 'bucks down' himself. These are, as a rule, simple ores involving no particular difficulty in the fluxing, as the object of this part of the course is to obtain skill in fusing, cupellation, and parting. Scorification of silver ores and fire-assay of lead ores is also taught at this time. Enough checked samples are kept on hand so that no two students are working on the same ore at the same time. The ores are handed out three or four at a time in order to keep the student systematic in his method of working. This work, on a basis of two afternoons a week, occupies the remainder of the first semester.

The first part of the second semester is spent in assaying difficult ores and metallurgical products by the different standard methods, as the excess litharge and nitre, iron nail, and scorification; and the limitations and advantages of the different methods shown for different types of ores, such as heavy sulphides, arsenides, antimonial and zincy ores, tellurides, hematite and limestone ores, speiss, copper and lead bullion. Checked samples and pulps of these ores are kept on hand for this purpose. The assay of gold and silver bullion, the combined method for copper bullion, and the handling of metallic particles, and any other special methods which may be considered necessary, are also taught.

Training in Speed

Acquiring speed and accuracy combined, and the handling of a comparatively large amount of work with dispatch, are inculcated by spending a whole day in the laboratory instead of two afternoons, as it is impossible for a student to accomplish any large amount of work when limited to a 3-hr. period. It is also absolutely essential that the student have his own muffle and entire set of apparatus, including the pulp-balance, although two students may use the same button-balance without interfering with one another. This part of the course is during the last half of the second semester, and consists of from six to eight whole days in the laboratory, depending upon the quality of the work turned out by the student. Commencing with six samples on the first day, the number is gradually increased to twenty-five on the last. These samples, which are checked pulps, are handed out in the morning and the results expected that night. All kinds of difficult ores and metallurgical products are included in these samples in order to give the student practice. If more than three out of ten of the assays do not check closely with the originals, the whole number have to be re-run until they do. When the student can run twenty-five duplicate assays on unknown ores and have three-quarters of them check within 0.5 oz. on silver and 0.03 oz. gold on a fifty-ounce ore, he is considered as having satisfactorily accomplished the course and should be able to hold his own in an assay-office. During the course over three hundred determinations are made for gold, silver, and lead, many of them being repeated several times. The practical value of the last part of the course appeals to the students, and they have voluntarily given up Saturday as being the only whole day available for the work.

Gold Dredging in the Philippine Islands

In the Philippines four dredges were reported as operating during 1912. The most important project during the year was that of the Philippine Exploration Co. on the Gumaus river. The 5½-cu. ft. dredge, built by the New York Engineering Co. for this company, commenced operations in October. The first clean-up was 275 ounces.

The company expects to handle 85,000 to 90,000 cu. yd. per month and that the average recovery will be in excess of 30c. per cu. yd. The dredge was built at a cost of about $150,000 and the life of the property is estimated at five years. The old Stanley dredge, which has been idle for two years, has been taken over by a new local syndicate known as the Maximall Gold Dredging Co. The hull has been thoroughly overhauled and found to be in fair condition, and the company began operations in October on the upper part of Paracale basin with F. W. Pearson as dredgemaster. The Paracale Proprietary Co. is operating the old Paracale dredge on the Paracale river, and has two dredges under construction. The first should be completed by the end of the present year and the other a few months later. The combined capacity of the two dredges, it is claimed, will be 100,000 cu. yd. per month. The old Paracale dredge has recently been overhauled and repaired. The old Risdon 3½-ft. dredge on the Maliguit river, under the supervision of John A. Bruce, handled from 15,000 to 20,000 cu. yd. per month. Frank B. Ingersoll and A. J. McDonald are planning to place a 5½-cu. ft. dredge of the close-connected type on the Malaguit river. Some ground on the Umiral river below the mouth of the Oyongan is controlled by Australians who are constructing a dredge. The ground has been prospected and the average value has been estimated at 35c. per yd. It is reported that a small dredge was purchased by H. E. Nelson for work on the Mariguina. It is only claimed to have a capacity of 100 yd. per 10 hours. Several areas were examined in 1912 with a view to building dredges if results were favorable and there seems to be a field for small dredges in the Philippines.

Drilling at the Mount Royal Tunnel

By L. B. Schwarz and G. H. Gilman

*A double-track tunnel, 3½ miles long, is being driven through Mount Royal, the high ridge behind the town of Montreal, in order to bring the tracks of the Canadian Northern railroad into the heart of the city, where a new terminal station is to be built. This work is being done by Mackenzie, Mann & Co., Ltd. Work on the tunnel was begun in July of last year. It is being advaneed at four main headings, one from the west portal, two from Maplewood avenue shaft, and one from the Dorchester street shaft. The rock is limestone of medium to hard texture, cut by trap dikes.

The drilling work is carried on by means of Sullivan 'FF-12' light-weight water drills, with 2⅝-in. eylinders, of which 18 are in use, and Sullivan 'UH-2' 3⅝-in. water drills, of which 15 were recently purchased. These drills are operated by eompressed air at 100 lb. pressure, supplied by six 100-cu. ft. belt-driven cross-compound eompressors and two 2000-ft. direct-connected motor-driven cross-eompound air-compressors.

SECTIONAL VIEW OF SULLIVAN WATER DRILL.

Sullivan Water Drill

As this is the first large piece of work in which the Sullivan water drills have been used in numbers, some detailed description of these machines will be interesting. Engineers have devoted much time and study to the problem of clearing drill-holes of cuttings. In a rock that makes sludge rapidly, as for example, shale, slate, and some porphyries, difficulty is experienced in cleaning the holes regardless of the angles at whieh they are drilled.

In a free-drilling rock, which ordinarily may be cleared by throwing water into the hole, depending upon the churning action of the drill-steel to eject the cuttings, this same difficulty is experienced with dry holes. This objectionable feature has been overcome to some extent by the use of a water jet, from a hose nozzle, but an arrangement of this kind practically requires the services of an extra man, since the desired results may be obtained only when the drill steel is reciprocating, and further, the amount of water required will in many cases prohibit the use of such a device. Wtih these points in mind, the Sullivan water reciprocating drill has been developed. This is an ordinary rock-drill of the reciprocating type, with a piston and rifle bar bored out to permit the insertion of a small tube, adjustably secured in the back head of the machine. Water under pressure is conducted by a hose line and fittings to the mouth of this tube, through which a constant jet passes into the hollow piston rod and thence into the hollow drill-steel, held in the chuck of the machine. The hole through the drill piston is enlarged for a certain distance from the point at whieh it ends in the counterbore for the rifle bar, and the function of this enlarged opening or secondary counterbore is to conduct an impulse of exhaust air from the rear of the piston chamber down through the hole in the piston, when it withdraws from the lower end of the tube, which happens at the instant of reverse on its forward stroke.

These details are shown in the sectional view. The action causes a charge of mingled air and water to pass through the hollow drill-steel to the cutting face of the bit, which, with the water which passes through when the piston is lifting, has the effect of ejecting the cuttings in the form of sludge from the drill-hole. It also insures a clean rock surface for the bit to strike, and prevents the hole from 'mudding up', regardless of its direction.

When working under normal conditions, air from the cylinder is not admitted to the hollow piston until after the valve is reversed, with the piston on its forward stroke. The air consumption of the machine is therefore exactly the same as if there were no water-tube, because the air which would ordinarily be exhausted by the valve passes through the drill-steel, and no live air can be admitted for this purpose.

If, however, the conditions of the ground warrant it, a charge of live air from behind the piston may be directed into the drill-steel, and this will be followed by the impulse of exhaust air as the piston nears the forward end of its stroke. This may be accomplished by pulling the tube farther back into the head, and then securing it by screwing down the lock plug upon the rubber sleeve. By thus manipulating the water-tube, a varying proportion of air and water may be admitted to the drill-hole to handle to the best advantage the particular kind of rock being drilled.

The water-tube is secured in the back head by the

*From *Mine and Quarry.*

rubber sleeve and gland or lock plug just mentioned. Water is introduced through a water elbow and hose fittings, which include a spud containing a screen to prevent foreign matter from entering the tube, and a screw cap to keep out dirt when the hose is disconnected. A removable plug is provided to limit the amount of water admitted.

Water-Supply

Water under a pressure of from 50 to 100 lb. per square inch is required for clearing the hole of its cuttings. If it is not possible to procure this by other means, a pressure tank may be employed, in which, after being filled with water, the desired pressure is secured by admitting to the tank compressed air at pipe-line pressure. At Montreal the supply is brought in under pressure from pumps and distributed to the drills in the headings by a manifold.

DRILLING SIDE-HOLES FOR WIDENING.

The amount of water entering the drill should only be such as to make a heavy paste of the mud. Using more water than is necessary for this purpose is objectionable, because it requires frequent filling of the water-tank and does not increase the cutting speed. It also is apt to get more water into the drill, in various ways, making it harder to lubricate. The amount of water required will vary with different kinds of ground, and if the $^1/_{16}$-in. opening in the water-spud of the drill is not large enough to suit conditions, the hole can be drilled out larger or another plug with a larger opening substituted. In the event that the cuttings do not come from the hole as readily as desired, the water-tube should be drawn back into the rear head by ⅛-in. stages, in order to allow more air to mingle with the water passing through the drill-steel. This should be tried before increasing the water opening, and if satisfactory results in cleaning the hole cannot be obtained by increasing the air-supply as suggested, more water may be introduced by enlarging the opening in the spud. When the air consumption of the drill is an important item, the water-tube can be pushed forward into the piston and this will cut down the amount of live air used through the drill-steel.

Round hollow steel is ordinarily used with this drill, and requires no shanking. The bit in common use is the regular cross shape, similar to that commonly used with solid steel. Lubrication is provided by the automatic differential-pressure oiler, used first on Sullivan light-weight drills. This consists of a chamber cast in the drill cylinder and holding about half a pint of lubricant. Oil from the chamber is drawn into the chest by the pulsations of the air in it. The speed is controlled by two small ball check valves screwed into the top face of the cylinder and connected by ports with the oil chamber, so that oil is conducted to the inlet opening in the chest. It is then carried through the machine in the form of a spray.

General

The general operation of this drill is the same as that of the ordinary reciprocating or so-called piston machine. It has the advantage of not requiring the use of any external means of extracting the cuttings, which permits it to be kept in continuous operation from set-up to tear down, excepting for time required to change drill-steels. A little practice on the part of the operator will enable him to adjust it to meet to the best advantage the existing conditions of ground and air pressure, and when this is once accomplished, remarkable drilling speed results.

Drilling Speed

The 'FF-12' water drills at the Mount Royal tunnel are mounted on horizontal 11-ft. heading bars, with a leg or support in the centre to secure stiffness. Four drills are used at once on this bar. When the rock is unusually hard, three double-screw mining columns are used instead of the bar. Two drills are mounted on arms on each of the two outside columns, and a fifth drill on the centre column. In one heading the drills have cut as high as 20½ ft. per hour per drill. This does not include setting up, but does include changing steel and lining up holes. The average depth of holes is 5½ ft., and the average speed per drill hour 16½ ft. In sinking a shaft with 7-ft. cut holes and 5-ft. line holes, an average of 8.6 ft. per hour per drill was maintained (total drilling time). In another heading where the rock is harder, the four drills cut in October, 13 ft. per drill hour, or eight 5½-ft. holes in two hours, total drilling time. The steel is 1⅛-in. gauge, and holes are drilled for 1¼-in. powder.

Water-piston drills are being introduced in Missouri, but performance figures are not yet known.

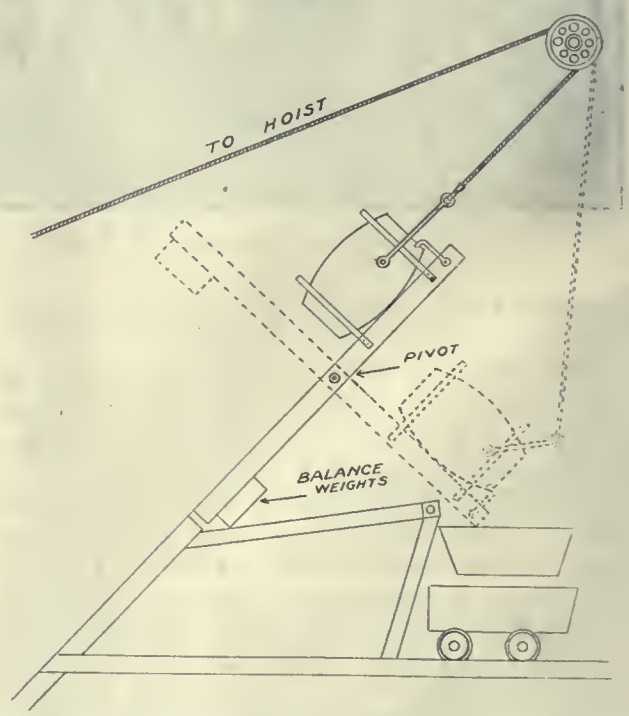
Concentration by Flotation

At the annual meeting of the Minerals Separation, Ltd., it was stated that nearly 2,000,000 tons of zinc, lead, and copper ores are being treated by the company's process yearly, while the following interesting comparisons with other concentrating processes were made by the chairman.

In the up-to-date mines of the United States and elsewhere, where several thousand tons of ore are treated daily, I understand the modern practice is to erect complete self-contained units, each designed and equipped to crush, and concentrate, or treat about 1000 tons per day. Complete plans of such 1000-ton units have been furnished to Mr. Broadbridge, the company's chief engineer, and on that he bases his figures, which have been summarized as follows: First, for an ordinary wet-table and vanner concentration unit to treat 1000 tons per day there are, in the particular mill referred to, 174 tables and vanners, occupying a building or floor space of 41,580 sq. ft. The power required to drive these amounts to 175 hp., and the cost of installation is approximately $120,000. This, of course, refers to the concentration plant alone, no crushing or power plant being included. Second, to replace this mill with a Minerals Separation flotation plant will require only two units of 600 tons each, capable of handling 1200 tons of ore, instead of 1000, and will cost about $20,000. The housing or floor space required will be less than 3000 sq. ft., compared with 41,000, and the horse-power to drive it only 80 to 120 at the most, according to the number of agitators. The additional cost of suitable re-grinding mills recommended will, at the outside, amount to $30,000; adding this to the cost of Minerals Separation flotation plant, the total will then only amount to $48,000, compared with $120,000 for the former unwieldy, and less efficient plant. The extra re-crushing plant forms no part of the purely Minerals Separation process plant, although it is recommended and included, because of the enhanced profit it will ensure. To make this clear, take a 2% copper ore, from which under the best table and vanner methods a possible 70% recovery may be assumed, so that with copper at 12c. per pound the yearly yield will be $1,226,400. Estimating an 85% recovery by Minerals Separation, because all minerals can be freed from the gangue by better crushing, thereby making the higher recovery easily possible, and assuming on a conservative basis that fully 50% of the crushed ore will need re-crushing at a cost of 20c. per ton, and allowing also for the additional cost of smelting, the net results will work out as follows: With copper at 12c. the yield will be $1,459,109, showing a balance of $232,709 to the good, which, again, is equivalent to over 60c. per ton of ore net, or more than sufficient to amortize the whole of the cost of Minerals Separation plant, plus that of the extra fine-crushing plant, in less than three months' operation. In other words, the copper produced from a 2% ore will cost at least 1c. per pound less to produce, the effect of which on the copper production of big mines, and of the world, will be self-evident. In a mill handling 2,000,000 tons per year, of which there are more than one in the United States and elsewhere, the two systems appear to be still more instructive and convincing. With wet, or table and vanner concentration, a plant of this capacity would require 850 concentration tables and vanners, occupying a floor space of over 200,000 sq. ft., consuming not less than 870 hp., with a capital outlay of over $620,000. A Minerals Separation plant, on the other hand, to treat this quantity would only require nine units occupying a floor space of not more than 15,000 sq. ft., would cost less than $100,000, and would require only 400 to 450 hp. If it were found necessary to fine-grind the ore, an additional $144,000 should be added to the above figure, raising the cost to $240,000. In capital outlay alone, the table and vanner plant would, therefore, cost 500% more than a Minerals Separation plant of equal capacity, or over 150% more than a Minerals Separation plant, plus the additional re-crushing plant recommended. The production of copper, assuming 85% recovery (in many cases we have reason to expect to get a recovery of 90%), would be increased from 51,000,000 lb. to over 62,000,000 lb. The net saving would amount to $1,163,547, taking copper at 12c. per pound.

A Self-Dumping Hoist

At small mines and prospects automatic machinery is quite as important as at large ones, and many a dollar may be saved by simple contrivances. One such is illustrated below in a self-dumping hoist as used by the Arcade M. & M. Co. It is especially



adapted to prospecting work on inclined veins. The counter-weight should overbalance the empty but not the loaded bucket. The whole arrangement is easily and cheaply built. We are indebted to C. F. Spaulding for the sketch.

Flotation by the Potter-Delprat process is conducted at a comparatively high temperature. Minerals Separation uses 60 to 70°, and the De Bavay and Elmore normal temperature.

Diamonds in British Columbia

By J. A. Macdonald

A year or more ago it was announced that diamonds had been discovered in British Columbia. Not much has been heard about the matter since, nor have any notable finds of diamonds been reported in the past year. That diamonds really are found in British Columbia is the announcement of R. W. Brock, Director of the Geological Survey of Canada. Stones of commercial value have been found in the glacial drift across the international boundary, in Illinois, Ohio, and other states. These have no doubt come from Canada, but the original locality has not yet been found.

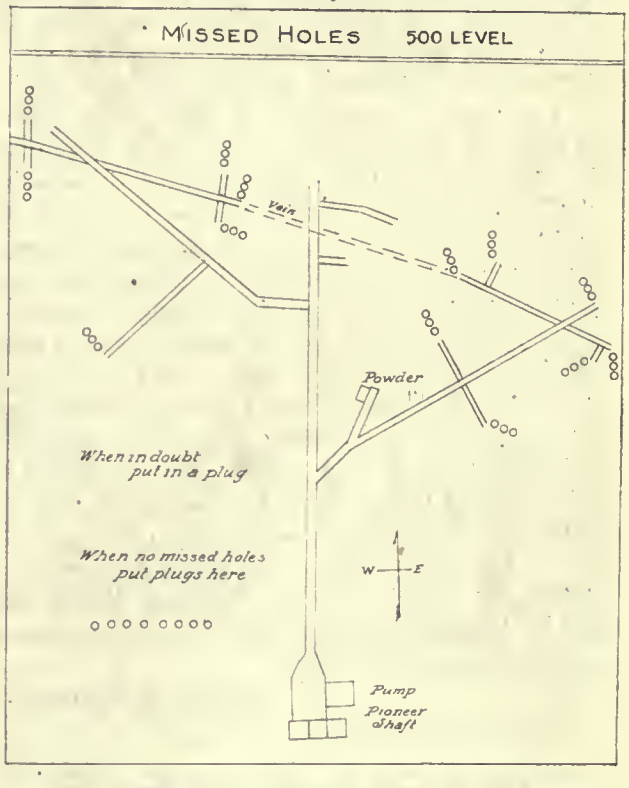
The rock now found to contain diamonds in British Columbia is a peridotite of the variety known as dunite, consisting of olivine and chromite. The rock specimens in which the diamonds were found were collected on Olivine mountain, near the Tulameen river, where C. Camsell, an experienced member of the Canadian Geological Survey, had been making an examination on behalf of that organization. Samples of the rock were submitted to W. A. Johnston, mineralogist of the Survey, to ascertain the nature of the chromium minerals. In the course of his examinations Mr. Johnston secured some insoluble fragments of crystals which appeared to be diamonds. More of this material was separated, and a series of tests established beyond doubt the nature of the material. The individual crystals are small ones, none of them being larger than an ordinary pin-head, but many appear under the microscope to be clear and bright, and of a good quality. Some are yellowish or brownish.

The diamonds occur in the chromite, not in the olivine of the rock. The chromite occurs as short, irregular, vein-like segregations an inch or more in width, in irregular masses, and as small disseminated grains through the rock. Gold and platinum also occur in the chromite. On account of the small size of the diamonds and the limited distribution of the chromite, the discovery is of scientific rather than commercial importance. It is possible that placer deposits in streams draining peridotite rock masses may contain stones of greater size, although the fact that placer-mining for gold and platinum has been carried on for a number of years without any such discovery having been made tends to lessen the probability, since stones of commercial size in the sluice-boxes would be apt to attract the attention of the miners.

The peridotite in which the diamonds occur is often weathered to serpentine. It is interesting to note that it is closely related to the rocks which form the matrix of diamonds in Arkansas and South Africa. This should be encouraging to prospectors. The discovery of diamonds in British Columbia was not altogether unexpected. The Geological Survey officials working there had for some time been on the lookout for them. Some years ago R. W. Brock obtained a few microscopic crystals which were believed to be diamonds, and which gave positive results in all tests to which they could be submitted. As a result of this prospectors were notified to be on the lookout for diamonds. This discovery is a genuine one, and no surprise would now be occasioned by the discovery of diamond-fields. Prospectors should keep a sharp lookout.

Missed Holes

The following method of informing the miners of the existence of missed holes is in use at the Gold Hill mine, Quartzburg, Idaho. A smooth board of convenient size is made for each level and hung on the wall of the change-room. A rough sketch of the level is drawn and, by using a small brush with drawing ink, a suitable map is made to enable each man to identify his own working place. At the end of each drift or cross-cut, on the map, three small holes are drilled. If a miss occurs, a small plug is put into the first hole of the corresponding drift; if two misses, into the second; and if three, into the third. It is noted upon the board that in case of doubt it is best to put in a plug. Should there be a question as to in which drift the miss occurred, as it is hard to distinguish when several shots are fired in drifts that are close together, put in a plug for each drift. Should no missed holes occur, all the plugs will be in a place arranged for them on the side of the board. The accompanying diagram explains this simple and efficient method.



Attention has been called to errors appearing in the article on 'Operating Costs of California Mines' by Charles Janin, in the *Press* of October 26, last. The cost of development at the Fremont Con. should have been $0.383; that of mining at the Gwin, $1.95; and the development cost given, $0.257, should have been added to the total mining cost $2.50 as printed in the company report. Mining cost at the Central Eureka should have been given as $2.82 in place of $2.85.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Progress in Mexico

The Editor:

Sir—In your issue of January 11, under the heading 'Progress in Mexico in 1912,' you state: "The Southern Pacific, which opened its West Coast line to the Tepic capital early in the year, has done no construction work." This is true from the Tepic end, but is not true of the Guadalajara end of the Southern Pacific railroad. The Southern Pacific built 9 kilometres of road for the benefit of the El Favor, Mololoa, and other operating mines, extending its lines from Magdalena to the present terminus, La Quemada, constructing bridges, completing the grading, and laying the rails and has built a splendid depot and sidetracks: and the El Favor Mining Co. has built a warehouse at that point costing $12,000. All ores have been delivered to that point since November 9, 1912, which marked the opening of that extension for traffic. As we have sent out information to several thousand people, interested with us in the Hostotipaquillo field, stating the above fact, we thought some criticisms might be made of the apparent conflict in the statements we have made and those which we have quoted from your report above. It will not be difficult for you to verify these statements, as we are sending fully 20 cars of freight per month from the new station; it is connected by telephone and telegraph with Guadalajara, and the agent from Magdalena was moved to the new station. This construction required an appropriation of $100,000 (gold) from the Southern Pacific railroad in Mexico and trains have been in continuous operation since November 9.

MAKEEVER BROTHERS.

New York, January 17.

Blast-Furnace Smelting with Crude Oil

The Editor:

Sir—Your timely editorial on the use of crude oil in blast-furnace smelting brings to my mind some additional facts pertinent to the inquiry. A great many attempts have been made in this direction, naturally enough, considering the obvious nature of the proceeding and the probable advantages which it should have under the conditions prevailing in this state. Where petroleum is so abundant and cheap it is most evident that its successful application in smelting would be attended with great advantages. In regions like California, where coke, the customary fuel in blast-furnace smelting, commands an excessive price, and where on the contrary the liquid fuel is extremely cheap, there can be no question of the desirability of employing the latter could means be found of rendering its employment perfectly feasible. As has often been remarked, the heat units are there, and only the details of its use remain to be settled.

I have been at much pains to procure information as to the various attempts that have been made to employ oil in smelting in the blast-furnace; attempts which began much farther back than most people are aware. I have seen an illustration of an antique and crude form of cupola devoted to melting pig iron, which was published fully 30 years ago, exhibiting the pipe connections by which petroleum was to be fed into the furnace—evidently in connection with the blast. It entered at the tuyeres, and it may be observed that while provided with means for atomizing the oil, the combustion was intended to take place wholly within the shaft. Of the propriety of thus burning the liquid in the melting zone I will speak hereafter. The next instance of the use of oil in this style of work that I shall instance, was the proposal of W. L. Austin, the celebrated metallurgist, the father, I may say, of pyritic smelting, to employ oil jets in the tuyeres of his furnace, not especially for the heat thus to be gained, but for the special purpose of preventing the formation of deposits of the magnetic oxide of iron, by which he was troubled at that time. I think Mr. Austin took out patents for such application of petroleum, but I am not aware that his invention came into practical use.

Subsequent to Mr. Austin's proposal Mr. Nesmith of the Colorado Iron Works at Denver invented a method of heating the blast of smelting furnaces by burning petroleum within the air main. His apparatus consisted virtually in an enlargement of the main, affording space for the development of the flame of one or more jets, the gaseous product of which, along with the unconsumed air, went on into the furnace. This involved, of course, the provision of refractory linings in the main and its connections. By this means the blast was effectively heated, but the method was criticised on account of the vitiation of the air, which lost a portion of its oxygen, taking up instead a corresponding amount of CO_2 and water vapor as the result of the combustion of the oil. I was under the impression at that time and later that the loss of active oxygen thus brought about was of a serious nature; but reflection convinces me that the proportion of oxygen thus sacrificed is likely to be too small to affect the smelting process noticeably, and I regret that I expressed antagonistic views thereon. It is easily capable of demonstration that the blast may be even highly heated without losing more than a fraction of the total oxygen, and there is also the consideration that if, as is usual, the blast of air proceeds unimpaired into the shaft it still requires to be heated at the expense of fuel, and of its own oxygen. It is now difficult to see why the preliminary heating which it would undergo by either Nesmith's or Austin's method would prove in any way destructive or prejudicial to the smelting process. Another important consideration here supervenes: the preliminary heating can be done with greater economy than the subsequent heating; since the fuel expended in the Nesmith (and probably in the Austin) device would be thoroughly burned, the end products being CO_2 and water; while the coke upon which we otherwise rely for the inter-furnace reactions, is largely converted into carbon monoxide. The reader will appreciate this according to his knowledge of the reactions in furnace metallurgy.

What would be gained by such an application of oil would evidently rest upon the saving in cost of oil versus coke, added to that gained by the more perfect combustion of the former. Some rough calculations may make the possible savings quite perceptible and important. A pound of the ordinary coke sold on this coast sets free approximately 13,000 heat units when completely burned,—that is, to carbon dioxide. A pound of oil produces nearly or quite 20,000, when burned equally thoroughly. Oil is therefore worth fully one-half more than an equal weight of coke under the same conditions as to perfection of combustion. In California crude oil may generally be had for $1 per barrel, more or less, depending on the cost of transportation. Allowing six barrels to the ton, oil costs about one-third as much as coke, which under similar circumstances may cost $12 per short ton, or $18 for a ton and a half, the equivalent in heating power of one ton of oil. Oil, therefore, whenever its use is permissible, costs only one third as much as coke. This computation would doubtless hold good wherever the matter is one merely of heat units, irrespective of the different behavior of the two fuels within the furnace. If the mere melting of a substance be the end sought, as of pig iron in the foundry cupola, or that of the materials within the open-hearth or copper reverberatory, there is no doubt that the monetary consideration holds. In the high iron, as well as in ordinary lead and copper-furnaces, where deoxidation by means of carbon is necessary, there would seem to be little likelihood of oil supplanting coke in spite of its greater heating power and less cost. However, there is much to be learned on this subject.

Concerning the complete combustion of crude oil within the tuyeres or before reaching them, experience has taught something of great significance. I have found by experience, and I dare say others have observed the same, that ample free and unencumbered space is essential for the proper burning of liquid fuel. If the space be restricted, or if the jet, atomized or otherwise, is directed against the materials to be melted, the oil is only partly consumed, and much carbon (soot) is set free, giving a very dense smoke, and in many cases a deposit of heavy difficultly combustible pitch is produced, which falling below the zone of fusion produces some ill effects. Even if the materials within the shaft are wholly incandescent and the combustion lively, as befits the smelting region, there is a waste of oil and the production of no great heat. The lesson learned from this is that the introduction of the liquid fuel directly into the furnace is not a workable method. It is true that in the lower part of the shaft of a pyritic furnace, as commonly run, there is much empty space, through which the currents of gas and air play comparatively freely; but if into a furnace thus working we proceed to inject oil, the immediate result is to lower the zone of fusion, by melting away the partly or wholly solidified matters (the 'noses', etc.) which support the charge above, permitting the whole mass to slide down, obliterating the cavities upon which the perfect admixture of the oil and air depends. When this takes place their blending becomes imperfect and the heavy smoke of unconsumed carbon is again produced, and the rate of smelting diminished. Such was the result of experiments in oil-burning when applied to lead-smelting some years since. The men in charge of that test declared that while the oil effected some apparent saving in the cost of fuel, the advantage was more than compensated by the diminished rate of driving and the attempt was given up. It appears then, in general terms, that oil cannot be worked in a close charge, and I believe that success is only possible when the liquid is applied to the preliminary heating of blast, which brings us back to the question so long argued in connection with pyritic smelting, as to the relative advantages of the heated and the unheated blast. This question, by the tacit decision of the metallurgical world, has been decided in favor of the unheated blast; but the possibility of employing so desirable and cheap a fuel as petroleum adds another chapter to the discussion. The question in its broad aspect is, can we substitute cheap oil for dear coke in some measure, and are there other advantages in the use of oil other than its superior heating power?

There is another advantage, of no mean significance in the use of oil, which I have discovered, and which I desire to call to the attention of practical smelting men. I have observed the strongest tendency on the part of the oil jet to prevent the customary obstructions about the mouth of the tuyeres. The heat bestowed upon the blast is sufficient to immediately liquefy the slag which otherwise would gather there and freeze into a nose, or partly close the exit of the wind stream. Everyone who has handled blast-furnaces recognizes the tendency to choke up the tuyere openings as a serious drawback in ordinary work, and will hail with delight any practicable means of obviating it. The result of the highly heated blast, or perhaps I had better say, the presence of the burning jet at that particular spot, is very favorable to the proper running of the furnace, lessening labor, and by reason of the unimpeded flow of the air-blast relieving the blowing machinery of much unprofitable work. I have used a fan in this connection, and I am convinced that it will deliver fully 50% more air when the oil jets are burning in the tuyeres than when delivering cold air, entirely because the tuyeres are kept free from obstructions. This is an advantage of great moment when large smelting capacity is sought.

Wallace Dow, of the Dow Engine Co., of Alameda, has constructed a melting cupola of his own invention, in which oil is the sole fuel. It has proved an unqualified success, melting with regularity the pig iron for the numerous castings manufactured by that company and doing it with an economy unapproached by coke-burning apparatus. I believe he saves fully three-fourths the cost of fuel by the substitution of petroleum for coke, and there is the greatest probability that through further experience the economy will prove still more decided. Not only is the melting done with dispatch, but the bath of metal may be kept fluid and in proper condition for pouring for many hours; in fact there is no reason why it may not remain molten for weeks, since the jets are so arranged in part as to play on the surface

of the metal. By this means it becomes possible to cast at any desired time. The problem before Mr. Dow differs from that which confronts the copper furnace manager, since in foundry practice it is necessary to supply all the heat of melting by the combustion of the oil alone, while in copper matting we get a great proportion of it from the reactions between the ore and the blast inside the furnace. In the one case the products of combustion must enter the furnace at a very high temperature,—perhaps as great as 3000° F.; while in the other the blast, to carry out all the desired objects, need be no higher as a general thing than 1000° F. Indeed it is generally conceded that with a blast of that temperature no fuel whatever need be used. It is necessary, therefore, to burn but little fuel for the preliminary heating, probably not more than enough to take up one-seventh of the oxygen of the air. In matting stacks there are required on the average about 1¾ tons of blast to each ton of material charged. To raise this weight of air to 1000° F. would require about 875,000 heat units, which is produced by 43.75 lb. oil of 20,000 heat units per pound. This is in the event that combustion is perfect and that there is no loss of heat in the operation. This is in the neighborhood of 7 gallons of fuel. I perceive that Thomas Kiddie has successfully used oil in this kind of smelting, and that he records a consumption of one barrel of oil to three tons of charge, or 14 gallons per ton. Probably Mr. Kiddie's results are more to be relied on than any merely theoretical calculations, although his published experiments related to only a short run. Mr. Dow has not as yet accumulated the facts necessary for precise statements of results, but since he has put his furnace into regular operation, it taking the place of two coke-burning cupolas, he will be able shortly to speak with authority on a number of phases on which there are at present only theoretical considerations for our guide.

Fully realizing the desirability of completely burning the fuel before its entrance into the cupola, Mr. Dow has provided his furnace with two heating chambers, one on each side of the shaft at the bottom, in which the atomized oil is brought into intimate mixture with the incoming blast, and from which the hot gases depart through broad apertures over the sole of the cupola. The heat is necessarily very intense, and its effect upon the firebrick of which the structure is composed is very marked. Better fire-resisting materials than the commercial bricks may be necessary for this purpose. Water-jacketing might be resorted to, but for a furnace which is out of commission the greater part of each 24 hours it seems hardly necessary. In this respect also the practice differs from lead and copper-smelting.

For my part I have taken out patents upon a form of construction which lends itself very well to the new requirements. My stack being supported on hollow columns and an encircling windbox, I have modified these to admit of the combustion of the oil inside of them, directing the highly heated blast to the interior of the stack through tuyeres lined with refractory materials instead of the iron pipes commonly employed. Each supporting column conveys and heats the blast, being lined with firebrick and provided with an efficient burner, by which the oil is injected downward so as to meet and be consumed by the incoming blast, which rises from subterranean pipes connected with the blower. By this means I still retain the feature for which my furnaces have been noted, that of no visible air connections. As I am about to put in operation one of these furnaces I shall take pleasure in later communicating to your readers the economic results of my work.

HERBERT LANG.

Oakland, California, January 15.

Secretarial Ethics

The Editor:

Sir—Referring to the editorial under the above caption published in the *Mining and Scientific Press* of January 25, I do not feel called upon to submit an answer to your criticism of matters pertaining to the policy of Institute excursions, since I did not originate that policy and am not responsible for it. My personal management of the excursion to Japan was investigated by a special committee, appointed at my request at a joint meeting of the directors and the Council, comprising C. F. Rand, chairman, Karl Eilers, and Edward L. Young, the last named being selected as particularly familiar with conditions in Japan. I have Mr. Rand's permission to make public the report of this committee, which follows:

New York, January 8, 1912.

At the first meeting of the Council of the American Institute of Mining Engineers held after the return of the excursion to Japan, Mr. Struthers being present, requested that a committee be appointed to receive and investigate any complaints which might be made concerning his share in the management of the excursion. The undersigned were appointed such a committee. They have seen personally or corresponded with a considerable number of those who took part in the excursion; they have examined the accounts of Mr. Struthers at his request, and have listened to a statement from him. They have discussed the whole situation with other members of the Council and of the Board of Directors, and with other members of the Institute, and are about to make a report to the Council. Some of the facts hereinafter stated are already known to some of those with whom members of the committee have individually been in communication, but the committee thinks it well to repeat them in this statement.

The underlying cause of the few complaints which have been received is the fact that many of the members of the excursion did not fully understand Mr. Struthers' relation to it. They thought that while acting as Secretary of the Institute, he was not only absenting himself from his post, but making a personal profit in addition to his salary. Mr. Struthers did not receive a salary from the Institute while absent from the United States. The excursion was managed by him and by Mr. Vaughn, the latter especially qualified from past experience, but having no official connection with the Institute, entirely as a separate affair. It is unfortunate that the early circulars, which were sent out from the Institute office, did not make this as plain as might have been. The preliminaries of the excursion were undertaken by Mr. Struthers before he became Secretary, and, as we are Councilors, we are aware that upon his election as Secretary he desired to give up the management of the excursion, knowing he was needed at the office. Matters had progressed so far that, after discussion, it seemed wiser to have him carry out what had been undertaken.

It is the opinion of this committee, as well as that of

a considerable number of those members of the excursion with whom the committee has conferred, that the cost of the excursion was as low as could have been obtained by engaging a professional tourists' agent from the outside, and the committee is aware that for many months prior to the departure of the excursion, Mr. Struthers did a great deal of very hard and difficult work in preparation for the trip. Several of those who have communicated with the members of this committee have urged that in future no excursion shall be conducted by any members of its governing bodies.

This committee recommends that a special committee be appointed by the Council to study the entire question of future excursions by the Institute or its members, and to report to the Council their recommendations with respect thereto. After examination of the statement of receipts and disbursements, the committee are unanimous in the opinion that Mr. Struthers' compensation was much smaller than some of the excursionists seem to think and in our opinion no more than was reasonable.

CHARLES F. RAND, KARL EILERS, EDW. L. YOUNG.

A copy of this report was sent to all of the gentlemen in the Japan party, including the responsible editor of the *Mining and Scientific Press*. Several other statements concerning me personally I forbear to notice at this time.

JOSEPH STRUTHERS.

New York, February 1.

[We are glad to give publicity to the above letter from Mr. Struthers, but regret that he did not discuss the policy whereby, as we stated, "the position of Assistant Secretary and later of Secretary of the Institute, has been used to make money out of the members of the Institute in addition to the official salary," since our opposition is to policies and not to any particular individual. In discussing the matter we used only printed documents of the Institute. We did not print the report Mr. Struthers now quotes, as the copy which came to our office was marked 'confidential.' Since Mr. Struthers has referred to the matter, it is but fair to state that the investigation in question was only requested by Mr. Struthers after a formal petition asking it had been sent to the Council of the Institute signed by representative members of the Institute, and following an earlier flat refusal on his part to make any statement of receipts and expenditures to a committee of those participating in the excursion. When this investigation was made Mr. Struthers refunded $854.79 "for salary paid him while absent from the country on the Japanese excursion" and $550 which had been charged to the Institute for transportation from San Francisco to Japan and return and expenses in Japan of A. E. Vaughn as assistant. It is understood that at the same time it was agreed that advance payments made by members of the Institute who found themselves unable to take part in the excursion, and amounting to a considerable sum, should also be refunded. It is proper in this connection to point out that Mr. Struthers did not charge the Institute for his expenses on the Japan trip and that in the past advance payments made by members not taking the trip have been at times refunded and in other cases held. It is also proper to state that circulars regarding excursions have always announced that advance payments might or might not be refunded in such cases. Whether or not they were refunded has been, so far as public record goes, determined by the individual who would have profited by holding them. In the particular case cited, apparently, readjustment was necessary before the committee was able to report that the compensation was "in our opinion no more than was reasonable."—EDITOR.]

A. I. M. E. Secretaryship

The following circular letter has been issued in New York by Messrs. C. R. Corning and G. C. Stone, who, as members of the Committee of Five, are especially conversant with Institute affairs:

There are two candidates for Secretary of the American Institute of Mining Engineers. Bradley Stoughton, who was nominated by the Committee after long and careful deliberation, for the past year has been Secretary of the Iron and Steel Committee, and in that capacity has done excellent work and is largely responsible for the brilliant success of the recent Cleveland meeting. Joseph Struthers, the present Secretary, has been renominated by a number of his friends. Mr. Struthers' record is well known to the members, and the policy he has carried out, although he did not originate it, has caused a great deal of unfavorable comment. In view of the circular of January 27 asking for proxies to Messrs. Charles Kirchhoff and Karl Eilers to support the candidacy of Mr. Struthers, which request will undoubtedly be complied with by Mr. Struthers' friends, we urgently request that all those who are opposed to his candidacy and the policy he represents should promptly sign and return to us the enclosed proxy, which, as it shows on its face, is to be used solely for furthering Mr. Stoughton's election and for preventing the continuance in office of the present Secretary of the Council, Mr. Joseph Struthers. Although the vote for Secretary is not likely to be counted officially, it will be used in an attempt to influence the new Board of Directors in their choice of a Secretary. It is therefore of the greatest importance that all those who wish to see a change in the management and do not wish to have the Directors hampered in carrying out the changes should aid in the election of Mr. Stoughton.

Annual Meeting A. I. M. E.

The annual meeting of the American Institute of Mining Engineers will be held in New York, under the auspices of the local section of the Institute, February 17 to 20. The preliminary program provides for an informal social meeting and smoker at Institute headquarters, 29 West 39th street, Monday evening, at 8 p.m. The business meeting will be held at 10 a.m. Tuesday, February 18. Technical sessions will be held Tuesday afternoon, Wednesday morning and afternoon, and Thursday morning. Tuesday evening F. H. Newell will address the Institute, and Wednesday evening will be devoted to a formal banquet and reception to the president of the Institute. Luncheon will be served in the Institute building Tuesday and Wednesday.

Special Correspondence

NEW YORK

THE FAR EAST AND GOLD.—NEW COPPER PRODUCTION.—WETTLAUFER MEETING.—CRIPPLE CREEK.

As an underlying condition of importance, the financial situation in the Far East continues to attract large attention, especially in London. In answer to a question by one of the members of Parliament, the India Office stated recently that the net imports of gold into India for the year 1912 amounted to £27,637,627, and the sales of council bills and telegraphic transfers to £28,173,143. Moreton Frewen, the famous bimetallist, in commenting upon these figures, states that there must be deducted from the amount derived from the sale of bills and telegraphic transfers what is known as the home charges, amounting to £17,000,000, making a net amount of about £11,000,000 to be added to the net gold import—a total of £39,000,000 in gold absorbed by India last year. Mr. Frewen calls attention to this absorption of yellow metal, saying that it is to be hoped that the publication of these "sinister figures" will put both the India Office and the financial district of London on guard. Further, in this connection, the *Statist* calls attention to the fact that India's absorption of gold does not increase the available supply of money in the Indian money markets. The Bank of Bengal has recently advanced its rate to 8%, and withdrawals of silver from the currency department have been so heavy that the Indian Government has again been forced into the silver market. The movements of cash balances in the Indian banks are held to indicate that the gold now being remitted to India does not get into circulation. How far the production of gold is responsible for some of the apparently anomalous conditions existing is a matter of much discussion among theorists and would-be economists, and however construed, may be said to have little or no effect upon the mining of gold as an industry. Quite a contrary state of facts exists as to the mining of silver, the latter metal being on a commodity basis, and if conditions in the Far East will justify a further slight increase in price on some fairly permanent basis, it will mean much activity in both new and old districts where for some years the net profit to be won from the production of silver has been so slight as not to justify operations. The precious-metal miners are compelled to look to India and China as important factors in the future of the industry. According to the generally accepted theory, any such hoarding of gold as is estimated by Mr. Frewen would both perpetuate and intensify the so-called high cost of living, against which such world-wide protest is now being made.

In the copper market, the trend has been for the most part against any improvement. It is anticipated that there was an increase during January in surplus stock of somewhere between 7,000,000 and 12,000,000 lb. This is based upon an estimated refinery output of something above 135,000,000 lb., while sales, so far as known, indicate a combined domestic and export demand of about 125,000,000 lb. The tensity of the Balkan situation has not been without effect, and the result has been renewed weakness in the London market. The metal touched 16c. in New York, recovered about ½ point, and at the moment the market is a very sluggish one. There is a good deal of figuring being done on the amount of new copper which the mines are preparing to turn out, and this will be one of the chief elements in the fixing of price levels. If present prices are maintained, there will be a great deal of activity in those properties that have been rejuvenating themselves and are now just about ready to begin production once more. The Superior & Boston has resumed shipments to the Old Dominion smelter, and is shipping ore from its eighth level which is taken out in the course of development work. The Shannon Copper Co. is rapidly getting upon a basis where it can show a fair degree of profit on the present copper market. The company produced in September 143,000 lb. of copper at a cost of 13.85c.; in October, 210,000 lb., at a cost of 14.83c.; in November, 436,000 lb., at a cost of 12.71c., and in December, 362,000 lb., at a cost of 12.54c. During the quarter covered by these figures, $40,000 was expended in development and charged to production cost. As a result, ore has been opened on the lower levels showing 9 to 11% copper.

Among the Lake Coppers the important questions for a long time has been the possible life of the Calumet & Hecla. The company has recently adopted a policy of conservation as regards the conglomerate lode, and is maintaining its rock tonnage from the other developed lodes on its property. The result is a decreased net production for the Calumet & Hecla, as the Osceola lode shows an average of about 15 lb. of copper per ton as against 30 lb. for the rock mined from the conglomerate. This policy means that the Calumet & Hecla can maintain its present output for twenty years. The directors of the Chino Copper Co. are to meet on February 28, and it is expected that action will be taken on the company's initial dividend. The rate has not yet been determined, but it is expected that $1 per share quarterly will be paid. On the same date the quarterly meetings of the Utah Copper Co. and the Nevada Consolidated will be held, but no change in the rate of distribution by either of these companies is expected.

The minority interests of the Federal Mining & Smelting Co. are combining to bring suit to declare null and void the present contract existing between the company and the American Smelting & Refining Co. Some effort has been made to adjust the matter without litigation, but no statement has as yet been made by the officials of the smelting company. If the litigation is eventually begun, it is said that a receiver will be demanded.

GOLDEN CYCLE MINE.

The annual meeting of the Wettlaufer-Lorrain Silver Mining Co., Ltd., was a stormy affair, and the present administration was sustained by only a small plurality and, as a matter of fact, this was done only after a deal of hustling for proxies among shareholders. It has been a matter of considerable discussion as to how far the selling of Wettlaufer has been for the account of so-called 'inside' interests. The report of Fred Hellmann, the consulting engineer, in summing up the condition of the property, is as follows: "The known orebodies have been exhausted by the year's operation, development so far has failed to uncover any new orebodies, and a program of development is being carried out with the object of finding further orebodies, or determining, in so far as this may be done, with a reasonable outlay, that none such exist. The future of the property will depend upon the result of this development work." This issue, at one time spoken of a second Kerr Lake, both being in the hands of the Lewisohn interests, has sold down to merely nominal prices.

The merger which is to be made a holding company for the principal Cripple Creek properties is gradually taking shape. A $25,000,000 securities company is proposed, to hold the various transportation lines in the district and to take over the El Paso and Golden Cycle. Later possibly the Vindicator, the Elkton, the Isabella, and others will be included. The shareholders of the Pittsburgh Silver Peak G. M. Co. are to receive a 2% dividend on February 15. The rumor which has been circulating as to a pos-

sible consolidation of the American Zinc, Lead & Smelting Co. with the Butte & Superior is emphatically denied by the inside interests in both companies. The Hayden-Stone people are represented on the directorates of both companies, but it is said there is no ground for talk of consolidation any further than that the present community of interest insures harmonious action. Consolidation of the St. Joseph Lead and the Doe Run Lead companies has reached the appraisal stage, and a joint committee of experts is shortly to make an examination and report on both companies. When this shall have been done, a plan for further action will be submitted to the stockholders. The forthcoming issue of convertible bonds to be made by the Granby has been underwritten by Speyer & Co. This underwriting marks the entry of one of the largest of the international banking houses into what is now for them a new field.

SPOKANE, WASHINGTON

SHORTAGE OF POWER.—NEW POWER-LINES.

The need of more power for the cyanide plants at Republic is a hindrance to the treatment of the ores to full capacity. At the North Washington Power & Reduction Co. mill it is planned to cut out the Chilean mill, install a second tube-mill, running the two tube-mills in tandem on ¼-in. mesh Lone Pine ore. At the San Poil Consolidated Co. mill a remedy for slow grinding is being sought by fastening strips of steel 18 in. apart to the barrel of the tube-mill, along the length of the cylinder. This is claimed to be an improvement, as the strips catch the pebbles, raise them, and cause them to fall with considerable force against the ore. In the San Poil mill ore averaging $10 is being treated at present, and about $4000 per week is reported as the amount of the bullion produced.

Several companies are looking for contracts to bring power into Republic, and among them are the North Washington Power & Reduction Co., through its manager, J. L. Harper; the Washington Water Power Co., of Spokane, and the Stevens County Light & Power Co. of Colville, Washington. The latter two companies would have over 100 miles of transmission-line to build before reaching Republic, so the North Washington P. & R. Co. has a marked advantage, having only about 30 miles to build, by connecting to the Bonnington falls line from Cascade, British Columbia, at the international boundary. Furthermore, this line is already under construction, while the two longer lines have not yet even been surveyed.

The Washington Water Power Co. supposedly has two engineers with four men each at the San Poil and Ben Hur mines, and two at the Republic mine, sampling for the purpose, as already stated in the *Mining and Scientific Press*, of interesting capital as a means of selling power. No information can be had from the engineers. A concern referred to as El Oro Mill Co. is securing land in Republic, beside the track of the Great Northern railway, for a cyanide plant for the treatment of ore from the Black Tail mine, owned by the Hope company.

A valuable body of ore has been opened on the 200-ft. level of the Ben Hur mine and developed for 40 ft. on the strike. It is said to be the richest body of ore ever found in the mine. Work has been resumed on the Laurier mine near Laurier. The Illinois Mining Co. is planning the construction of a barge, to be towed by a steam tug to Peach, a landing at the mouth of the San Poil, on the Columbia, and as soon as the Great Northern railway is completed to Peach, to begin transporting coke to that point and haul it seven miles up the San Poil valley to Keller, and then start up the smelter at the latter place.

At the Twilight group, on Jumbo mountain, in the Orient district, an adit, in 40 ft., is following a well mineralized vein. A contract has been let for development work by the Mogul Mining Co. on a group of claims northwest of Pierre lake for $6000. Fine sulphide and native gold ore is reported from the last shot in the White Elephant mine. The Napoleon mine, near Marcus, is sending about 2500 tons of ore per month to the smelters. A rich discovery is reported at the Swamp King mine.

In the Galena Hill mine, at Rock Cut, a deposit of ore, 7 ft. wide, assaying around $75 per ton, has been developed on the 170-ft. level, the first carload of ore from which will be shipped to the International Smelting & Refining Co. at Salt Lake, Utah. The concentrator on the Galena Hill property has been reconstructed and is operating satisfactorily.

The material for the concentrator for the Lead & Zinc Co. at Metaline is on the ground, and the lumber for its construction is being framed. The First Thought Mines, Ltd., has filed papers in a suit against Stevens county to have the tax levy of $14,036 for the years 1909, 1910, 1911, and 1912 against the First Thought mine declared void, alleging that for 1909-10-11 the property was assessed at $80,000 each year, and for 1912, $40,000; that for no time after 1908 did the property produce any ore of such value as to pay a net profit; that up to the date of cessation of labor on the mine the company had expended upward of $40,000 in diamond-drill and general exploitation, but had found no ore exceeding in value $4 per ton.

GRANTS PASS, OREGON

A NEW MILL.—RAILROAD CONSTRUCTION.

Equipment and machinery have been ordered for the Oriole mine, in the Galice district. The Oriole has been under development for several years, and has made a good showing, particularly in free-milling ore. Many valuable shipments have been made from the property. A mill and concentrating plant, to be operated by water power, will be constructed. The Vanguard mine, on Josephine creek, southwest of Kerby, is being rapidly developed under the management of C. E. Phillips, backed by outside capital. The ore contains free gold, tellurides, and some copper. A crew of 25 men will be employed on the claim through the winter. Mr. Phillips states that a number of other claims on Josephine creek are under development. Many men have lately arrived, being encouraged by the prospect of the Pacific-Interior railroad. This line will run within a few miles of the district.

Negotiations are under way by which the old Granite Hill mine, of Louse creek, will be rescued from oblivion. This well equipped mine has been idle for more than five years, litigation and flooded workings being the prime cause. The vein system is a good one, and it is believed the mine will 'make good,' once it is given a fair chance. Chicago people are the owners. Practically all that is needed to resume work is to unwater the mine, and mining men say that this could be accomplished by a double skip operated in the 2-compartment shaft of the mine. It has in addition to the 30-stamp mill and electric-power plant, one of the finest hoists on any Oregon mine.

The Good Luck or Swastika placer mine, of Jump-Off-Joe, is operating steadily this winter under the management of Cook & Howland. There are few surface mines in southern Oregon that have operated more steadily, and whose returns have been more certain, than the Swastika. Cook & Howland have owned and managed the property for a number of years. Two and three giants are employed, one of them being used much of the time on a grizzly elevator to remove the tailing. The mine has its own electric-light plant for night work. All the hydraulic mines are operating day and night. The rains have been heavy, and there is a good depth of snow on the ranges, so that a long and continued run of the monitors is probable. Gold is already coming to the Grants Pass banks, and a still greater quantity is shipped to the Mint. On Grave creek, Galice creek, Illinois river, Applegate river, Wolf creek, and all other mining streams of Josephine county, placer mining is in progress.

Three camps have already been established on the proposed line of the Pacific-Interior railroad that is to be built from Grants Pass to the copper and gold mines of southern Josephine county, and on across the Siskiyous to Crescent City, California. More than 150 men and half as many teams are employed in clearing trees along the right-of-way and in grading. Grants Pass recently voted

$200,000 bonds to be used in assisting this railroad, and more than three times this amount has been subscribed by mining and timber men. Crescent City people have also subscribed liberally to the railroad fund. Construction work has greatly stimulated mining in the isolated districts of Waldo, Josephine creek, and elsewhere south and west of Grants Pass.

Negotiations are under way by which a Michigan syndicate, headed by H. C. Russell, of Marquette, will take over the Blue Ledge copper-gold mine, of the Blue Ledge district on upper Applegate river. Mr. Russell went out to the camp this week and is making a thorough investigation of the mine. He was accompanied by several of the leading claim-owners and miners of the district, including J. F. Reddy, A. L. Jones, Walter McCallum, and Roger S. Bennett. Robert S. Towne, owner and manager of the Blue Ledge, is at the property, and met the party on its arrival. The Michigan people who are making negotiations to purchase, are heavily interested in the copper mines of that state, and if they take over the Blue Ledge they will develop and operate it on a large scale.

JOHANNESBURG, TRANSVAAL

NOVEMBER RETURNS.—FUTURE YIELD.—NUMBER OF STAMPS.

The November returns of the mineral output of the Union of South Africa show a decrease of £114,297, gold being responsible for £45,316. This was due to the short month and not to any decline in the gold-producing capacities of the Rand, which seem destined to increase for at least some time to come, not to decline as prophesied by H. C. Hoover. It does not, however, seem likely that in the immense stretch of reef-bearing country from Randfontein to Boksburg any marked increase in gold output can take place, and this portion represents the area from which the gold output in the past has been principally obtained. With the approaching exhaustion of several of the richest mines on the Central Rand near Johannesburg, it will be well if the present output is maintained over that stretch from Randfontein to Boksburg, but it is more likely to be slightly increased than otherwise.

Beyond Boksburg there is still a considerable area of goldfield, some of which is expected to turn out well, and but little unprofitable. So that it is to this Far East section of the Rand that all eyes are now turned to supply the increased output of gold on the Rand which for so many years has been such a conspicuous feature. There is also an untouched area southwest of Randfontein, but owing to its being covered by huge thicknesses of dolomite, its gold-bearing possibilities are but little known. Attempts to pierce this dolomite by shafts have not so far been successful, either on the East or West Rand, but providing the reefs are proved to be workable, there does not seem much doubt about the requisite capital being obtainable, as in other parts of the world more than double the water yet found in the Transvaal dolomites has been overcome. Until both the eastern and western extremities of the Rand are developed and producing it seems somewhat premature to talk of the rapidly aproaching decline of the Rand. Few authorities will dispute that in the majority of instances the yield of gold in depth per ton milled on the Rand is not maintained, and profits per ton may decline, but the large-scale workings necessary to reduce the costs will at the same time add to the total gold output, and perhaps the sum total of profits, if not to dividends to the same extent as formerly. This increase of total gold production and fall in the profits earned per ton has been conspicuous for some time on the Rand, and to all appearances is likely to continue. With regard to the present position of affairs in the gold-mining industry of the Transvaal, the figures for the November output are significant.

As a matter of fact, the Heidelberg and Klerksdorp figures ought to be added to those of the Rand, for they are nothing else but extensions of the Witwatersrand into the outside districts, and undoubtedly continuous with those of the Rand. Despite the conspicuous overshadowing of the outside districts by the Witwatersrand, Lydenburg and Barberton are making steady progress, the output of gold slowly but steadily increasing.

NOVEMBER GOLD PRODUCTION

	No. of mines.	Stamps at work.	Tube-mills.	Output, fine oz.

SALT LAKE CITY, UTAH

THE LEAD TARIFF.—OHIO COPPER.—STATE AID FOR RESEARCH.

Utah lead producers are beginning to feel easier over the tariff question since the return from Washington of the representatives who went there to present the producers' side to the House Committee on Ways and Means. W. H. King and George W. Riter, representatives of the producers' association, both expressed the belief that the Democratic Congress will keep a sufficient tariff on lead to protect the American mines, which are running on a rather close margin. Private advices from Washington to men interested are to the same effect. Some of the leading mining men in this part of the country are Democrats who favor a tariff on lead and zinc, and they are using their influence to the utmost in favor of the retention of a duty on these metals.

Ohio Copper is still the subject of a wide difference of opinion between the optimists and the pessimists. The latter have all kinds of dire things to say about the property, and their opinion has largely been reflected in the price of the stock. On the other hand, men connected with the operating department cheerfully predict large profits as soon as the remodeling of the mill is completed. December profits fell to $20,000, and the net earnings for 1912 were $305,400. At the mine it is declared that more ore is being uncovered than is broken down, and that in a comparatively short time an output of 3000 tons per day will be maintained.

Independent of the efforts to have the National Bureau of Mines establish testing plants in the West and take more interest in metalliferous mines, it is now proposed to have the state of Utah undertake mining research work. W. Mont Ferry, one of the best known mining men in the state, has introduced a bill in the state legislature appropriating $15,000 for mining and metallurgical research work by the State School of Mines at the University of Utah. "The purposes of the research department," according to the bill, "shall be to conduct experiments and research, either alone or in coöperation with the National Bureau of Mines and other agencies, with a view to finding ways and methods of profitably treating low-grade ores, of securing a higher percentage of extraction of metals from their ores, of obtaining other information which shall have for its object the benefit of the mining industry and the utilization and conservation of the mineral resources of the state."

While metal-mining in Utah as a whole is still waiting for a general awakening and the return of 'boom times,' the coal-mining industry is making astonishing strides. It is only a few months since the United States Smelting, Refining & Mining Co. consolidated several of the principal younger properties in Utah. W. G. Sharp, the president, is authority for the statement that the output has already been doubled, and the campaign of development is scarcely begun. A number of smaller companies have commenced operations recently, and the prospect is that the next few years will see an immense increase in the production of coal in Utah.

The Mines Operating Co., which has a lease on the old Ontario at Park City, has been having trouble on account of water shortage due to cold weather, but is again oper-

ating the new mill. Progress here is being watched with interest by metallurgists. Officials of the company claim that by the present process they will be able to mine and treat the low-grade silver-gold ore at a total cost of $4 per ton. The assays are said to run $8 to $12, with a saving as high as 80 per cent.

TORONTO, CANADA

HOLLINGER OUTPUT.—GOLD LEAF PURCHASE.—NEW RAILROAD.

The payment of the regular 3% dividend due on January 28 was accompanied by a frank and detailed statement by the officials of the Hollinger mine showing the curtailment of operations by the strike and the actual conditions now obtaining. The output is now about 80% of what it was at the outbreak of the strike, and the situation has much improved during the past few weeks. The value of gold produced the week previous to the strike was $51,769, which dropped the following week to $18,043. It fluctuated considerably for some time, falling as low as $10,816 during one week, but the new year witnessed a marked increase, the output for the first week of 1913 being $25,687, and for the week ended January 21, $41,000. The force of miners is still below normal, but there are 427 men now on the payroll and the number is daily increasing. The company has won a test case brought against some of the strikers under the Lemieux act. Three of the men were prosecuted for inciting and engaging in an illegal strike involving a breach of contract, and were found guilty. Two of them were sentenced to fines of $500 each, or 3 months imprisonment, and the third was fined $50, or 60 days in jail. An appeal from the decision has been taken. The main vein of the Dome Lake has been found in the cross-cut at the 180-ft. level, where it shows an improvement both in width and gold content, assaying about $32 per ton. The 10-stamp mill is being constructed and is expected to be in operation about the end of February.

The report of the general manager, presented at the annual meeting of the Crown Reserve at Montreal respecting the McEneany mine, estimates that there are 34,995 tons of ore from 40 ft. below the third level to the surface, which should yield a profit of $650,000. The shaft will be continued to the 500-ft. level. The vein at a depth of 400 ft. is 6 ft. wide, carrying free gold. The financial statement of the North Dome to the end of the year shows receipts of $104,103 and expenditures amounting to $103,366. The Gold Leaf Mining Co. is operating in the Kirkland Lake area in the Swastika district, where it has acquired the Boisseneault-Charlebois claims and is taking in machinery. The price paid for the property is stated as $250,000.

The Elk Lake branch of the Timiskaming & Northern Ontario railway was completed and formally opened for traffic on February 4. The operation of this line will greatly stimulate the silver mining industry of the Elk Lake and Gowganda districts, hitherto heavily handicapped by transportation difficulties, which caused the closing down of many promising prospects. Much freight is being prepared for shipment, including a carload of ore from the Miller Lake-O'Brien, of the value of $75,000. This company has purchased the Millerette, adjoining, and is utilizing its 10-stamp concentrating mill to treat low-grade ore. The Mann mine of Gowganda will also make a shipment. The Mann has developed a vein of 5 to 6 in. of high-grade ore at the bottom of the winze sunk from the 110-ft. level. The Powerful, another Gowganda company, has cut a 6-in. vein of good ore on the 150-ft. level, with wall-rock for a foot on either side impregnated with silver which will make good milling ore.

The new Casey-Cobalt shaft has been connected with the 250-ft. level. The mill is treating an average of 27 tons per day and making good recovery. The annual report of the Wettlaufer indicates that the mine is not likely to continue paying dividends at the present rate of 5% per quarter. Net profits for the year were $320,249, a slight increase over the previous year. The surplus, after paying dividends, was $36,931, a decrease of $63,971. The April dividend calls for $75,000, and it is believed that this will have to be dropped.

LONDON

NISSEN STAMPS IN SOUTH AFRICA.—KYSHTIM.

Mining men in the United States, and especially those in the Western states, are always pleased to hear of the success of their friends in foreign parts, so no apology is necessary for writing something about the Nissen stamp and its progress in countries under the British flag. During the past two years the stamp has been thoroughly tested at Johannesburg. Four stamps were erected at the City Deep mine, and the relative advantages of this type and of the ordinary 5-stamp battery thoroughly investigated. The results were given by P. N. Nissen in a paper read before the Chemical, Metallurgical & Mining Society of South Africa in October 1911, an abstract of which paper was published in *The Mining Magazine* for December 1911. It was conclusively proved in these tests that the Nissen stamp crushed more ore per unit of power, and that as regards the weight of the stamps the Nissen crushed a third as much again. The better regulated feed and the larger area of discharge are responsible for these improvements. The City Deep did not order any more Nissen stamps, because it was already fully equipped with other modern stamps for the capacity of the mine. But the Wernher-Beit-Eckstein group, the controllers of this mine, decided to adopt the stamp at other mines under its control, and has decided to purchase 64 for the extension of the New Modderfontein plant, in the Far East Rand. The group also intends to use the stamp in the enlarged plant at the Modderfontein B, but the number is not yet fixed. At the Fairview mine at Barberton, belonging to the same group, 2 stamps have been crushing to ¼-in. mesh at the rate of 35 tons per stamp per day; 2 stamps are also in use at the Rietfontein in the Lydenburg district.

The Consolidated Gold Fields of South Africa has decided to make the Nissen stamp the standard type for future construction and has ordered a large number for its mines in Rhodesia; namely, 56 for the Shamva, 36 for the Falcon, and 24 for the Golden Kopje. The plant at the Planet-Arcturus will also be equipped with them, but the actual number has not yet been determined. A great many smaller mines in Rhodesia and outlying parts of the Transvaal have adopted the stamp. Most of them are gold mines, but an interesting exception is the Liewpoort tin mine in the Rooiberg district, in the northern Transvaal.

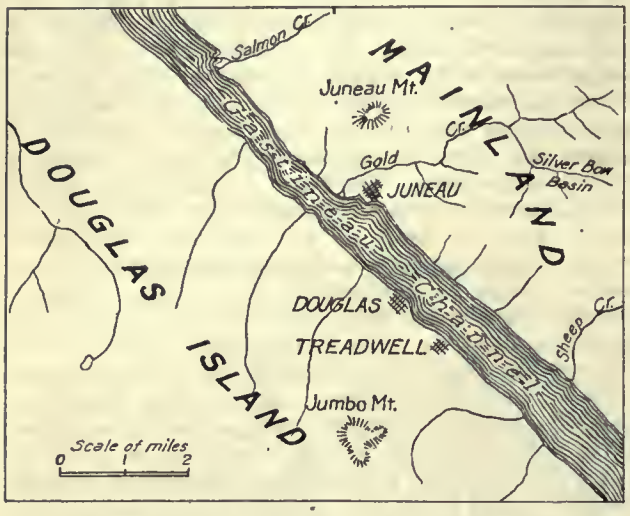
Your readers have been kept well posted on the doings of the Kyshtim Corporation, the company developing the copper resources of the Kyshtim estate in the Ural mountains. The technical management has been largely in the hands of American engineers, R. Gilman Brown being at the head, with Walter G. Perkins as consulting metallurgist, and H. W. Turner as consulting geologist. This venture is well established, so that closer attention is now being turned to the Tanalyk property, 300 miles or so farther to the south, not far from Orsk. The orebodies in the various mines belonging to this estate vary considerably. At first the average ore was supposed to be silicious, with fair copper and a relatively high precious-metal content, with barite occurring occasionally, and in some places zincblende. Exploratory work has shown that the amount of blende is present in larger quantities than was originally supposed. Moreover, the silver is associated chiefly with the zinc. At the Mambet mine, where most work has been done, the nature of the ore is shown by the results on the 105-ft. level. The lode is 15 ft. across, averaging 2.15% copper, 3.9 dwt. gold, and 2.9 oz. silver, with a large percentage of zinc. The copper mineral appears to be brittle and easily slimed. At the Graffsky mine, the copper is less than 1%, with about the same amount of precious metal as in the Mambet, and also a large proportion of zinc. Mr. Brown is, therefore, of the opinion that modifications will have to be made in the scheme of treatment, providing for the removal of the zinc and making a gold-copper and a silver-zinc product. T. J. Hoover has been consulted, and T. W. Draper has been appointed concentration manager. A small reverberatory will handle the less zincy ores.

General Mining News

ALASKA

JUNEAU

During December the Alaska Treadwell 240-stamp mill worked 20.09 days with water power and 6.54 with steam power, crushing 28,201 tons of ore; while the 300-stamp mill worked 14.87 days with water power and 11.79 with electric power, crushing 41,577 tons, the total being 69,778 tons. By amalgamation, $100,464 was saved, and by cyanidation



MAP SHOWING SITUATION OF TREADWELL MINES.

1416 tons of concentrate; the yield was $92,861, the total realizable value being $191,393. Operating expenses were $82,620, construction $25,004, and the net profit $83,769. Development covered 691 ft., and the stock of broken ore increased 3478 tons. The total output in 1912 was 892,192 tons of ore, yielding $2,161,319.

ARIZONA

GILA COUNTY

(Special Correspondence.)—The London Arizona Copper Co., aided by Dan O'Connell, has discovered a large body of silver-lead carbonate ore in its property. It is hoped that the profit from the ore will be sufficient to thoroughly develop the copper orebodies earlier discovered, and even to erect a smelter.

Winkelman, January 30.

(Special Correspondence.)—At the Inspiration property a station is being cut at the main west shaft. Both the main east and west shafts will be concreted. These shafts will have a hoisting capacity of 10,000 tons each per 24 hr., and probably a capacity of 7500 tons each for 16 hr., insuring a full supply for the mill in the event of disablement of one of the shafts. A 20 by 26-ft. station at Live Oak No. 1 shaft has been finished and a drift started from that point to connect with Live Oak No. 2 shaft.

At the Miami mine, one of the eight diamond-drill holes has revealed ore to a depth of 300 ft. below the 720-ft. level. In future the main shaft will be sunk to the 870-ft. level to extract the underlying ore. At the Captain shaft a large head-frame is almost completed, and the raise from the 420-ft. level has connected with the shaft at a depth of 200 ft. From that point another compartment is being stripped downward. When completed the shaft will consist of two compartments, one 4 by 4 ft., the other 3½ by 4 ft. The larger compartment will be used for hoisting rock extracted during development, the smaller will be used for counter-balance cages. Fortunately, all development at the Captain shaft will be in hard rock underlying the secondary enrichment zone. The shaft is being opened to take the place of No. 2 shaft, which, because of its situation in the orebody, will have to be abandoned. The electric hoist now at No. 2 shaft will be moved to the Captain. The 200,000-ton stockpile at No. 2 shaft is nearing exhaustion. J. Parke Channing has assumed direct charge of the Miami Copper Co. during the illness of B. Britton Gottsberger.

Government surveyors are marking the route of a transmission line that will convey electric power from the Roosevelt dam to Superior. It will tap the line now being built to Miami at a point near that town. Bringing in electric power will act as an impetus to development in this district, as the present cost of power is almost prohibitive.

An important discovery of high-grade ore has been made at the Superior & Boston mine, in the raise between the No. 6 and 8 levels. The ore is copper glance, 3 ft. assaying 31% copper with drillings into the hanging wall assaying 16% copper for a distance of 4 ft. The high-grade ore has thus been proved for a width of 7 ft., with the hanging wall not cut. The raise is now up 170 ft. above the No. 8 level, indicating a continuous orebody between the No. 6 and 8 levels, and this new find of glance ore at the present horizon leaves little doubt that this orebody will extend considerably higher. In the west end of the mine ore was mined to within 30 ft. vertically of the surface in this same vein.

Miami, January 30.

Copper production of Miami in January was 2,932,369 lb., as against 3,067,200 lb. in December. Ray Consolidated output in December was 3,830,000 lb., making a total of 35,931,402 lb. during 1912.

The Ray Consolidated Copper Co. has temporarily stopped construction work on the mill at Hayden, the eighth and final unit remaining unfinished. No reason has been given for this move.

GRAHAM COUNTY

(Special Correspondence.)—From September 1 to December 31, 1912, the Shannon Copper Co. treated 95,235 tons of ore which yielded 5,149,805 lb. of copper, 1012 oz. gold, and 54,394 oz. of silver, at an average cost of 13.49c. per pound. The high costs in September and October were due to taxes and liability insurance, while the large furnace 'froze' up in the latter month. The profit was $208,872, and on January 13 a 50c. dividend, amounting to $150,000, was paid. Development cost $40,000. In the west and sublevels of the Shannon mine, high-grade concentrating and smelting ore was opened for a length of 130 ft. over a width of 25 ft., and averaging 9.4% of copper. The Shannon-Arizona railway cost $715,000 to construct, and $414,000 bonds are outstanding. The new store, costing $25,000, is open for business. Liquid assets are $612,717, and current liabilities $174,649.

Metcalf, January 30.

MARICOPA COUNTY

In a west drift of the Cunningham Pass mine, 12 ft. of ore containing copper and gold has been cut. The Bullard, which adjoins the former, is shipping its ninth car of ore. Last week 18 in. of copper glance ore was opened.

MOHAVE COUNTY

C. Grimes, president of the Tom Reed Gold Mines Co., is inspecting the property. The Gold Road company has had trouble with its water-supply recently owing to the cold weather. The Elkhart mine, at Chloride, is being equipped with a plant for separation of lead, zinc, and iron. In the cross-cut of the Arizona Southwestern Copper Co. the vein is 16 ft. wide, carrying $24 per ton in gold and silver. A mill will soon be in commission, to treat 150 tons per day.

Quartzite district is busy, and prospects are good. The Cinnabar Development Co. has a new retort in operation. The Goodman mill is being overhauled. At the other small mines a considerable amount of work is being done.

YAVAPAI COUNTY

(Special Correspondence.)—Grading is being rushed on the new United Verde smelter site at Clarkdale. The T. F. Miller Co. has a store in operation there, and several temporary buildings are up. A modern brick plant of large capacity is ready to begin operations, and several big stacks of lumber are in readiness for use on the townsite. It is reported that the United Verde company will absolutely

control the new town by refusing to sell lots to outsiders. Lots will either be leased or the company will put up the buildings and rent to whom they please. An 8-in. pipe-line is being laid from the Kerwagen spring. The contractor has completed about half of the grading on the tunnel railroad line, from the 700-ft. adit to the smelter site.

The Arkansas & Arizona has been shut down about a week on account of motor trouble. The company has been working right along and has developed promising orebodies. The Haynes is employing about 25 men. This is a wet property, most of the water coming in above the 600-ft. level. The water is being caught there, and a large electric pump is being installed to force it out of the mine. A. J. Pickerell is loading a car of picked ore and concentrate from his properties near Prescott.

Prescott, January 28.

The Bagdad Copper Co. has three drills working, and over 100 holes have been put down. The United Verde Extension mine has been found to be in better condition than was expected, after being flooded for over two years. The Ford Mining Co., whose property is eight miles from Jerome, will prospect with a diamond-drill.

CALIFORNIA

Calaveras County

(Special Correspondence.)—A meeting of the business men of Angels was called last Thursday evening, at which ways and means to fight the Sierra railroad freight rates were discussed. There has been considerable hard feeling in this community regarding this matter, and the Railroad Commission does not seem inclined to interfere, regardless of appeals of Angels business men. Over $1000 was subscribed, and more is promised. The Utica people are getting ready to make their annual trip to the mountains to reconstruct their flumes. This is a yearly occurrence, and one would suppose that the work would be so constructed that it would be permanent. A large number of men will be employed. The Stanislaus Power Co. is making a few improvements at its power-plant on the Stanislaus river. It is planned to put in another pipe-line, which will place them at the head of the list with the largest power producers of the state. The Tanner Mining Co. is contemplating considerable improvements on its property. It has purchased from the Hercules-Horseshoe Mining Co. the 2-stamp mill and other buildings, which will be moved at an early date. A road is now being graded to the site of the new mill. J. A. Campbell is superintendent.

Angels Camp, January 31.

Eldorado County

At the Gopher Boulder mine, near Kelsey, the company has been unwatering the shaft preparatory to reopening the old gold producer. It is stated that an English syndicate intends bonding it and employing a fair number of men.

Inyo County

The Skidoo mill lost 16½ days time in December, and crushed 830 tons of ore. On December 15 the cyanide plant was closed for the winter. Bullion produced was worth $12,287, while total costs of $4790 left a profit of $7497.

Nevada County

During the coming spring it is probable that the old Covotoman and Young America gravel mines will be reopened by J. W. Rea. The old town of You Bet, once having a population of several hundred mining people, has only three families; and the well known flag-pole has been cut down for fuel.

The Queen Radigunde mine, in the Alleghany district, is the basis of a lawsuit between J. J. Guentherodt and E. E. Hoeft. After operating for two weeks on the Deer creek gravel beds, the Keystone drill is being taken to Yuba county. Results have not yet been published. San Francisco people are interested.

Placer County

The power plant of the Jubilee mine, on the Grass Valley road, is shut down for repairs and installation of a large boiler. The incline shaft is down 130 ft. A cave-in at the Red Jacket lead compelled Recknagle Bros. to suspend work. The new dredge for the El Dorado & Placer Gravel Mining Co., at Poverty Bar on the American river, is being rapidly constructed.

Plumas County

By an agreement of January 4, A. Weil will have control of the Rose Quartz group of claims, situated on Poorman's creek, for five years. Under the terms, the mine is to be thoroughly developed and a 5-stamp mill erected.

Shasta County

(Special Correspondence.)—The Oro Water, Light & Power Co. has taken a bond on the Gibson and other ranches just below Redding, and has set a force of prospectors at work. In the event of satisfactory results from drilling, it is planned to build a dredge. The properties are in the Clear Creek district. Porter & Taylor, of Los Angeles, who recently bonded the Russell holdings, have arranged to place 25 men at work early in February. The property comprises the Lost Channel placer claims, near Igo, and about 14 miles west of Redding. Work by the owners has disclosed good gravel.

Redding, January 28.

(Special Correspondence.)—A new copper ore deposit has been discovered near Heroult, by Fred Grotofend, locator of the famous Mammoth mine. The outcroppings were overgrown with brush, but the nature of the formation exposed resulted in investigation and location. It is probable a company of local and Eastern people will be formed to develop the holdings. Development at the Shasta Belmont group continues. Nevada capitalists are largely interested. The claims lie near Heroult.

KENNEDY 100-STAMP MILL.

Redding, February 3.

On January 28, at the Heroult iron smelter, seven miles from Kennett, a furnace was blown in to smelt copper ores by electricity and an oil blast. J. H. Loughrey experimented with a carload of ore from the Iron Mountain mine, and although not an entire success, results were promising.

The outlook at Whiskey Creek is bright. A 20-in. vein of rich ore is being opened at the Gambrinus mine, and a 5-stamp mill and two concentrators are working full time. A. Eggerton and F. Newmeyer have done well in the Mad Mule gulch. At the Mount Shasta mine a new ore-shoot, 2 to 4 ft. wide, has been cut. In New York gulch, M. Gannin's miners have driven a cross-cut to cut, 100 ft. below the outcrop, a vein that shows 2 ft. of good ore.

Tuolumne County

(Special Correspondence.)—What appears to be an important find was made in the Atlas mine, near Tuttletown, this week, when a cross-vein was cut on the 200-ft. level. Both veins are gold-bearing and at the junction are very rich. The housing of the mill is almost finished, and the work of placing the machinery has begun. About 30 men are employed in the mine and on the surface. The Longfellow Gold Mining Co., organized under the laws of Arizona, filed articles of incorporation in this county this

week. The principal place of business is Phoenix, Arizona, and the capital stock is $500,000, represented by 500,000 shares of the par value of $1 each. By its articles, the company's liabilities are limited to $50,000 at any one time. It is understood it will operate the Longfellow mine, at Big Oak Flat. The M. McCormick company has become sole owner of the Draper mine, near Soulsbyville, having purchased the interest which Cotton Bros. & Co. owned. The price paid, according to papers recorded here this week, was $40,500. The mine, which is 600 ft. deep, has been a good producer, but has been idle for some time. Approximately 100 mine locations have been recorded during the present month.

Sonora, January 25.

COLORADO

Clear Creek County

The new mill at the Pioneer mine, at Empire, is producing a clean product. The Capital mill is also operating steadily on company ore. Lessees at the Seven-Thirty mine are opening good ore. The old dump from the Burleigh mill has been cleared away from the site where the Edison mill is to be erected. The Marshall-Russell property is not being worked, pending a consolidation of a number of claims in the Empire district. The adit here is in 7000 ft., and should cut a number of veins. A new compressor plant is being erected at the Bellevue-Hudson mine, near Lawson. A large number of mines in the Daily and Atlantic districts have been closed for the winter.

Dolores County

The annual meeting of the Rico-Wellington Mining Co. was held at Provo, Utah, on January 30. During 1912 the production was 4700 tons of ore. The new mill for treating zinc ore is ready, but nothing definite has been done toward starting concentration of ore. Its daily capacity is 75 tons. An orebody containing copper, lead, and silver is being opened.

Gilpin County

At the Castle Rock mine, a shipment of 8 tons of smelting ore, containing copper and lead, assays $63.90 per ton. On the 400-ft. level the vein is 18 in. wide, showing improvement in driving. A carload of ore from the Two-Forty mine returned 4.75 oz. of gold and 8.5 oz of silver per ton. This came from the 200-ft. level. The property is developed by two adits, each 1000 ft. long, besides a shaft 340 ft. deep. At the Pittsburg regular shipments are made. With the Waugh No. 12 stoping machine one man has drilled 122 ft. in 6 hours.

Lake County (Leadville)

On January 27, 1905, the *Herald Democrat* stated that, in time, ore as low as 15% zinc would be profitably mined; and at the present time 17% ore is being shipped, and by March, the smelters will receive 15% zinc ore. This will be a boon to many in the Leadville district. There is little new from this centre, everybody being busy.

Ouray County

(Special Correspondence.)—The Wanakah mill worked 89 days during the quarter ended October 31, 1912, and treated 4469 tons of ore yielding a total of $48,232, the profit being $24,230. Development covered 707 feet.

Ouray, January 30.

Teller County (Cripple Creek)

A contract for the sale of control of the stock of the Golden Cycle Mining Co., which is held by Messrs. Milliken, Logan, and Carter, who, it is said, have 1,400,000 shares out of 1,500,000, has been signed. The sale involves about $5,500,000 for the mine and $1,500,000 for the mill, the latter treating 70% of the ore from Cripple Creek mines. Joseph Walker & Sons, of New York, who financed the El Paso Consolidated Co., has the option on the Golden Cycle stock. During the past week Joseph Walker, Jr., and others inspected the El Paso property. During January local mines paid $167,843 in dividends. The Vindicator produced 96,934 tons of ore worth $29.50 per ton, and lessees 10,775 tons, worth $18.50 per ton, in 1912. Royalties paid were $27,868. The annual meeting of the Mary McKinney Mining Co. will be held on February 10. During the past year the company produced 10,459, and lessees 3086 tons of ore, yielding $272,454 and $53,858 respectively. Total revenue was $328,028 and expenses $211,071, leaving a balance of $116,957. At December 31 the surplus was $77,670. A 2c. dividend, amounting to $26,185, was paid on January 28, 1913. Development to 920-ft. depth covered 4314 ft. A station is being cut on the 900-ft. level of the Nichols shaft of El Paso, and the ore-house is ready. Ore is being mined at three places in the Abe Lincoln property on Gold hill, the average grade in December being over $25 per ton. The flow of water from the Roosevelt drainage tunnel was recently 8485 gal. per minute.

IDAHO

Bonner County

At the Idaho-Continental mine, near Porthill, machinery is being assembled, coming from that place by sleighs a distance of 21 miles. The Union Iron Works, of San Francisco, is supplying three sets of rolls and other machinery. A hydro-electric plant has been erected about 10 miles from the mine, the 4000-ft. flume remaining to be constructed.

Lemhi County

The first consignment of precipitate from the Musgrove mill has been received at Salt Lake City, Utah people being interested in the property. The mill has a capacity of 25 tons per day, and at present is operated by steam, but when water-power is available a profit should be made from ore over $3.20 per ton. By the manager, R. L. Edwards, the following details are given of the mill, which type is coming into favor in several countries:

The Lane mill, running at a little over 5 r.p.m. (the proper speed is 8) will crush one ton per hour so that 95% passes 200 mesh. The tailing on the first charge (the charge was agitated) assayed only a trace. At the present time we are not able to keep up sufficient speed on the mill and run the agitator too, with the small boiler, so are crushing the ore a little coarser and not agitating. It leaches better than one would expect from the amount of slime in the ore. The highest tailing sample so far has assayed only 80c., but the ore we have run has been very low, averaging $4.80. The precipitation is perfect, and cyanide consumption is low, so it is settled that the mill is going to do fine work.

We figured on getting some help from the water-power in the winter, but we did not get connected up with the flume.

Shoshone County

The Federal Mining Co. has purchased the Frisco mine, at Gem, its 500-ton mill, and water right on Canyon creek for $250,000. This mine has paid $1,250,000 in dividends since 1889. The Frisco Consolidated company has 15 separate properties. The Frisco mine is 600 ft. west of the Morning mine, which belongs to the Federal company, and has been developed to a depth of 200 ft. by 20,000 ft. of workings. Originally it produced lead and silver ore, but the percentage of zinc has increased, so that the mine was practically abandoned. The process at the Morning mill will successfully deal with this ore.

The Stewart Mining Co. made a profit of $536,900 during 1912. About 500 tons of ore is shipped daily. In February the Bunker Hill & Sullivan M. & C. Co. paid dividend No. 185 of $65,400. This makes the total amount of dividends paid $14,042,550.

KANSAS

Cherokee County

On January 14 a slab of rock, 5 by 18 by 45 ft., estimated to weigh over 200 tons, and a large piece of limestone, fell from a drift in the Hartford mine, near Galena, and killed four men, while another was badly injured. Twenty-one men worked hard at rescue operations.

MONTANA

Silverbow County

(Special Correspondence.)—The Boston people who

brought suit to annul the decision of the Parrot company to sell its property to the Anaconda Copper Mining Co. for 90,000 shares, are still fighting the case. A short while ago, evidence was taken at Butte bearing on the sale, the witnesses being Anaconda officials. The minority holders, who are trying to have the sale annulled, contend that the property is worth far more than was paid for it; while the Anaconda company claims that, as it had been an unprofitable property, the payment was ample. Owing to a scarcity of water, the Barnes-King mill is treating only 100 tons of ore per day, but in the spring there will be plenty. B. B. Thayer, president of the Anaconda Copper Mining Co., is now at Butte on his semi-annual inspection of the properties. A good deal of activity prevails in the Georgetown district, the extension of the Butte, Anaconda & Pacific railway into that part having made the improvement. The vein on the 2000-ft. level of the Tuolumne mine is 30 ft. wide, with 9% copper and good silver content. Shaft-sinking is being continued.

Butte, January 30.

NEVADA

Esmeralda County

(Special Correspondence.)—The estimated production of the Goldfield Consolidated Mines Co. for January was 27,265 tons of ore, yielding $505,000. Operating expenses were $175,000, leaving a profit of $330,000.

Goldfield, February 3.

During the last quarter of 1912 the Goldfield Consolidated Mines Co. produced $1,255,782 from 86,294 tons of ore, at a cost of $510,248, leaving a profit of $745,533.

On the hanging wall of the 100-C raise, in the Vernal mine, there is an 8-in. vein which carries high-grade ore showing free gold, and with it there is 30 in. of lower grade ore which can be mined at a good profit. On the 50-ft. level a cross-cut is being driven. Regular shipments are being made. Salt Lake men have acquired control of the Round Mountain Mining Co. The mill is treating 180 tons per day, and 90% is extracted by grinding and amalgamation. During 1912 some good developments were recorded to a depth of 900 ft., and on the lowest level 12 ft. of ore is being driven on. Placer-mining has been done to some extent by lessees on the Sunnyside claims of the Round Mountain. The Goldfield Oro shaft is being enlarged from 350 ft. to the surface

Humboldt County

Rochester Canyon has a population of about 800 people, there being three towns close together. The Rochester Hills Mining Co. has an adit in 52 ft., in hard ground, and at 115 ft. it is expected to cut a vein at 100-ft. depth. With the Big Four people, a tramway 1750 ft. long will be erected. There are 4000 sacks of ore on the Big Four lease which is to be sent to the Thompson smelter. To supply the new centre with water, a supply can be brought by gravity from Lee's springs, while for electric light and power it is proposed to erect a power-plant at Oreana, on the Southern Pacific railroad.

Lyon County

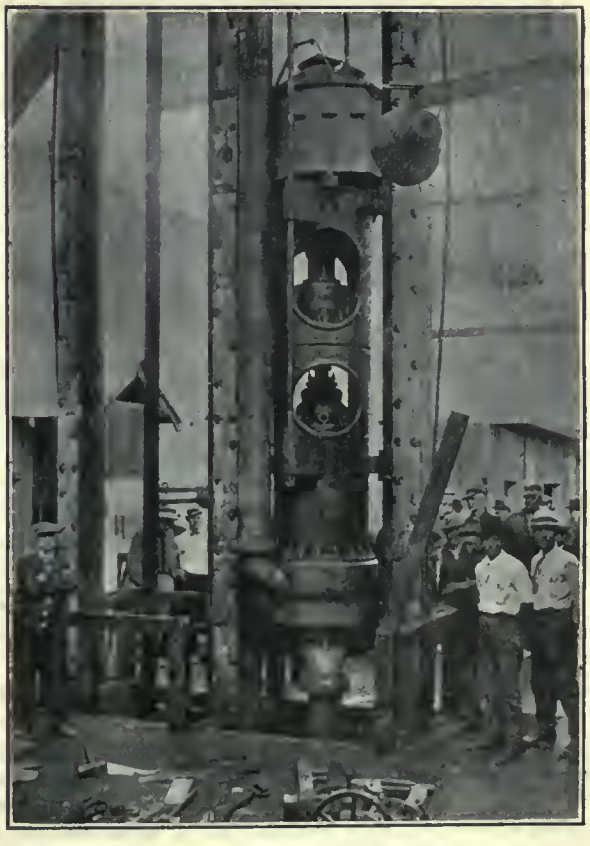
During the past year the Thompson smelter received ore from 125 different copper properties in western Nevada. There has been a decline in Mason Valley stock, due, it is stated, to the company borrowing money on unsold stocks of copper. At the Nevada-Douglas mines, 250 men are employed, and ore shipments for the week ended January 9 were 3063 tons. A new orebody has been cut in the Berryhill adit, almost directly under the 'big stope' of the Douglas Hill mine. At the Ludwig, the incline shaft is down 68 ft. below No. 7 level, in ore averaging 2.5 to 10% copper. Leaching experiments have reached the stage where a 10-ton experimental plant is to be erected. It is believed that 1.5% ore will yield a profit by this process.

Nye County

The following development was reported by Tonopah mining companies during the week ended February 1: Ten mines shipped to the mills 11,090 tons of ore worth $231,635, including Jim Butler, 450 tons; Merger, 165 tons; North Star, 45 tons; and Midway, 45 tons. The year to date shows a total of 52,870 tons, worth $1,104,832 from all mines. Between the 565 and 615-ft. levels, the Montana Tonopah cut 16 ft. of good ore. On No. 6 level of the Jim Butler the shoot has been driven on 100 ft., showing 6 ft. of ore at present. Improvements at the MacNamara mill have been finished. The Extension opened good ore on the 600-ft. level. Sinking of the Belmont main shaft has been resumed, it being in trachyte in the footwall of the vein. During the quarter ended November 30, 1912, the Tonopah Mining Co. produced $702,368 of bullion, from which mining, milling, and general expenses left a surplus of $374,654. Sundry receipts and T. & G. railroad dividends brought the revenue to $448,335. Dividends absorbed $400,000. Cash on hand amounts to $416,831.

Storey County

The annual meetings of the Crown Point, Belcher, and Yellow Jacket mining companies were held in San Francisco last week. The combined report states that the Yellow Jacket mill treated 7787 tons of dump ore and 21,660 tons of mine ore, during 197 days, valued at $144,549. The Crown Point mined from the 1400-ft. level, and winze to 1450 ft., 17,826 tons. The three companies shared expense in repairs to the Yellow Jacket shaft, tramway, and bin, and are preparing to unwater the mines by pumps at Gold Hill. Generally the condition of the mines and finances is satisfactory. During the week ended February 1 the Mexican mine produced 1315 tons of ore worth $37,099; and the mill treated 442 tons yielding $13,658, with 92% extraction. An up-to-date mill is to be erected in the Six-mile canyon, using the Fischer plant for a start. This has 5 stamps, and the capacity will be increased to 50 tons per day. It will treat ore from the Comstock-Phoenix mine and other claims.



CENTRIFUGAL PUMP AT COMSTOCK.

White Pine County

Nevada Consolidated Copper Co. produced 70,800,244 lb. of copper in 1912, as against 63,048,997 lb. in 1911.

TEXAS

Brewster County

(Special Correspondence.)—Closing of the Del Carmen mines in Coahuila, Mexico, is announced. These mines are

in the foothills on the western side of the Sierra del Carmen and belong to the Madero family. They were worked for lead for several years by the Kansas City Con. S. & R. Co., but recently have been operated for zinc. The mines are 15 miles from Boquillas, Texas, and the ore has been delivered by aerial tram to the north side of the Rio Grande. From Boquillas to Marathon, on the Southern Pacific, 82 miles, the ore has been hauled by mule-team. A new type of auto truck was tried, but proved unsatisfactory. The cost of delivery of ore, coupled with disagreement between Texas and New York men interested in the operation of the property, has led to closing the mine. As the

TERMINAL OF DEL CARMEN TRAMWAY.

custom house at Boquillas has been closed, it is now impossible to bring in the ore economically.

Marathon, January 20.

SALT LAKE COUNTY

At the meeting of shareholders of the four Alta mining companies, mentioned in these columns last week, to agree to consolidation, the Columbus Extension holders disapproved of the proposal, holding that it would not benefit the mine. The meeting was adjourned. During 1912 the Ohio Copper Co. produced from 757,000 lb. of copper in February to 187,000 lb. in October, when the strike was in progress, and profits ranged from $37,000 to $20,000 in December. The year's output was 6,952,700 lb., and profits $305,400. Assets total $500,000. The Utah Copper Co. produced a total of 95,105,391 lb. of copper in 1912, as against 99,456,225 lb. in 1911.

SUMMIT COUNTY

Five mines at Park City shipped 1843 tons of ore during the week ended January 25. Snow has interfered with mining in the Snake creek district. At the Ontario mill, water pipes and solution-tanks have been thawed out, and the roasting-furnaces fired up.

TOOELE COUNTY

At the International smelter, No. 3 lead furnace has been started, and No. 4 will be ready by February 15, giving a total capacity of 1000 tons of ore per day.

WASHINGTON

STEVENS COUNTY

The Standard Chewelah company has opened a rich vein of copper ore in its shaft two miles from Chewelah, and is installing a boiler and pump to unwater a deeper shaft on the property. An east cross-cut is in 175 ft., and with 75 ft. more the vein will be cut. A compressor will also be installed, and ore shipments will begin in 60 days. The United Copper Co. held its annual meeting last week. The gross revenue during 1912 was $226,000, and the estimate for the current year is $662,500.

WISCONSIN

GRANT COUNTY

(Special Correspondence.)—There is much interest now among zinc miners in various new types of drills. The Leyner one-man drill has been introduced in many of the mines and is rapidly replacing two-man drills. The Vinegar Hill company uses it entirely and pays on a footage basis. Homer Snow has put the Leyner in at the Empire mine. At the Frontenac the Temple air-electric drill is in use, while the Mineral Point Zinc Co. is getting excellent results with the Ft. Wayne electric. In average ground 145 ft. was driven recently in 45 shifts. The wide distribution of electric power through the district favors introduction of power drills. The Mineral Point Co. has not found much in the Merry Christmas, a tract of ground worked years ago but long idle, but is expecting good results from the work being started at the Black Jack, south of Galena. This property was worked heavily in the nineties, shipping to the Illinois Zinc Co. At Highland, matters are rather quiet. The Highland Mining Co. has sold out to the Mineral Point company, leaving the Franklin the only independent mine of importance.

Platteville, February 1.

CANADA

BRITISH COLUMBIA

So far $1,324,554 has been spent by the Granby company on its Hidden Creek mines, and a further $1,620,000 will be necessary for full equipment on a 2000-ton daily capacity. During the past six months the smelter at Grand Forks has yielded a profit of $790,054, and the surplus is $1,095,575.

ONTARIO

The Crown Reserve Mining Co. produced bullion worth $1,692,060 in 1912. Total expenses, including $147,910 royalty to the Ontario government, were $556,050, leaving a profit of $1,130,010. Dividends paid totaled $1,061,288, and the surplus stands at $821,392.

During the week ended January 25, 20 tons of gold-bearing ore was sent out from the Tough claims at Kirkland lake, near Swastika. Ten Cobalt mines shipped 327 tons of ore, and two 65,164 oz. of bullion, the total of the latter for the year being 247,615 oz. The Hollinger mill treated 43,227 tons of ore in 1912, yielding $933,974. The average assay was $22.45 per ton, and extraction 96.3%. It is estimated that the Dome mine produced $750,000 in 1912, which, with other small mines, makes the Porcupine output for the year $1,800,000. The main vein has been cut on the 180-ft. level of the Dome Lake mine, where it is 30 in. wide, worth $32 per ton.

NICARAGUA

Recent reports are to the effect that the La Luz & Los Angeles M. Co. will make improvements at its property to the value of $500,000. George Fletcher, the managing director, visited the property recently. The Bank of Nicaragua, in which Eastern capital is involved, was recently started.

PHILIPPINE ISLANDS

The new dredge of the Philippine Exploration Co. on the claim at Gumaus, is at work. F. B. Ingersoll, president and general manager for the company, states that an Australian company is operating two dredges in the river at the town of Paracale. The company had an old New Zealand dredge. This concern was incorporated as the Philippine Dredging Proprietary, Ltd. The Philippine Dredging Syndicate was operating a Risdon dredge in the Malaguit river, and was recovering about 300 oz. of gold per month. Up in the country at the junction of the provinces of Rizal, Tayabas, and Nueva Ecija, on the upper waters of the Umerai river, the Luzon Gold Co. is getting gold, using hydraulic power.

New York Metal Market Review

January was an eventful month with the metals, especially copper, because of the tumble in prices of that metal. The first month of the year ended with a net decline of about 1½c. per pound for electrolytic, while at one time the market was 1¾c. below the recent 'peg' price of 17.75c. which the producers demanded. While the statistical report for December had great influence in bringing about the decline, foreign conditions were quite as potent, and it may be repeated, as stated in the November review, that European demand must revive before great improvement can be expected. The situation demonstrates the importance of Europe as an outlet for American copper. Tin prices, with intermittent trading, have been more than maintained. Lead has been dull, but prices have remained stationary. Spelter is much lower, and antimony is down also. Lead, spelter, and antimony have all been affected by uncertainty as to tariff changes.

Copper

At the beginning of January, electrolytic copper was quoted at or near 17.62½c. cash, 30 days, delivered, New York. At the end of the month quotations were 16.30c. cash, 30 days, delivered. Until the appearance of the Copper Producers' statement on January 8, the market was strong and optimism was general, as for several weeks there had been a hardening of prices and improvements in domestic sales. Late in December between 7,000,000 and 10,000,000 lb. had been taken by one large consumer at the market price. The disclosure by the Producers' report that nearly 20,000,000 lb. had been added to stocks in December, on the heels of which came disturbing reports of renewed hostilities in the Balkans, caused a break in London, and an immediate softening of prices here, especially of those quoted by second hands. Futures were affected first, but quick delivery metal soon followed in the decline. One break followed another abroad. They were reflected here, and the word 'demoralized' began to be heard with reference to the market. About the middle of the month, outside lots of copper sold down to 16c., and there were rumors of still lower prices. The large agencies indicated that they were willing to take concessions, and for the first time in many months it was evident that the producers were not standing together. The low prices were followed by an incomplete recovery and in a steadier market; sales were reported at 16.40c. cash, c.i.f. New York. Then came another break abroad, and between January 10 and 15 standard or speculative copper dropped £6, and in the week between January 18 and 25 electrolytic for February and March delivery was offered down to 16c. f.o.b. New York, and even lower prices were rumored. It also became known that two of the largest agencies, the United Metals Selling Co. and the American Smelting & Refining Co., were sharply competing for business abroad, and once more talk of demoralization was heard. Then came a sudden turn for the better, and several million pounds was taken by London dealers at 16.25c. f.o.b. New York. The market hardened toward the end of the month, prices rising to 16.35c. cash f.o.b., with March and April offered at a concession of 25 points. Throughout the month domestic consumers appeared distrustful of the market and did not come forward to buy except as necessity compelled them. Lake near the end of the month was quoted at 16.50c. cash, New York. Brass sheets, wire, and rods were reduced ⅛c. on January 27, and copper wire also was off a fraction of a cent. The feeling on the part of some speculative dealers that lower prices are to be expected in copper is shown by their willingness to sell short in futures. This is a form of gambling which is vigorously condemned by those who do a legitimate business in the metal. Exports were fair in January, considering the situation, amounting to 23,048 tons.

Lead

The price of lead has been maintained throughout January. Early in the month an active demand resulted in good sales which strengthened the market. The activity soon subsided, however, and quiet then ruled throughout the month, the price standing at 4.35c. New York. While some bullish talk was heard early in the month, it is not believed by careful students of the market that there will be any undue or rapid rise while the tariff question is pending.

Spelter

The month opened with 7.30 to 7.35c. New York quoted for spelter, and with shipments good, but not much new business. The trend of prices throughout January has been downward, and at the close 6.80c. New York was quoted. Large quantities of German spelter, which was sold on the Atlantic seaboard at 5 points below the market price of prime Western, made its appearance, and this influence, together with tariff uncertainties, has had a detrimental influence on both prices and trading. The weakness which developed late in the month was regarded as surprising in view of the small stocks and good consumption. Despite the low price, buyers held aloof.

Antimony

Declines marked the antimony market in January. Probabilities of tariff changes are a disturbing influence with this metal also, although buyers have stayed out of the market to a considerable extent for the reason that they were sufficiently supplied. Throughout the month the metal was dull and irregular, with pressure to sell, but few takers. Near the end of the month quotations were 9.50 to 9.75c. for Cookson's, 9.25 to 950c. for Hallett's, and 8.50c. for Chinese and Hungarian grades, having declined from 9.87½ to 10.25c. for Cookson's, 9.50 to 9.75c. for Hallett's, and 9c. for Chinese and Hungarian. The appearance in the market of speculative lots has not helped trade, and at times it required a good deal of shopping to get the 'rock-bottom' price.

Aluminum

Prices of this metal have dropped a little in the month, and both prompt delivery domestic and foreign are now quoted at 26.25 to 26.50c., a decline of about 25 points. Consumption has continued good, though perhaps not quite as brisk as in the last quarter of 1912. In the early part of the month it was confirmed that the Aluminum Company of America has obtained riparian rights in North Carolina and Tennessee, and has plans in prospect for a new aluminum plant, to be operated by water power. Good freight rates and the labor supply will determine the location of the plant. Until the water power is available it is planned to secure electricity from the Tennessee Power Co. It is expected that the new plant will be ready for operation by the middle or latter part of the present year. Extensions are planned by the same company, it is understood, at its plant at Messina, New York, part of which will be available this year.

Tin

Tin prices held up throughout the month, opening at 50.60c. and closing a trifle lower, but over the 50c. mark. There were periods of dullness followed by others of considerable activity. In the first half of January there was a shortage of spot and prompt delivery metal, and prices went from import cost to nearly 60 points above it, and declines in London were not followed by the New York market. The arrival of the *Minnetonka* from London, January 15, with 1025 tons, was all that averted a serious situation. As it was, some dealers who did not have metal to cover their contracts were pinched. Later in the month further generous arrivals eased the shortage, and the premium gradually vanished. In the next few weeks quiet is looked for, inasmuch as February and March tin was freely dealt in during November and December. The arrivals in January were 4169 tons, and there is afloat 3075 tons.

The sale of 2500 tons of Banca tin in Holland, January 29, brought the high price of 137¼ florins (equivalent to 50c. c.i.f. New York), and it is declared that it had all been contracted for before the auction. Reports are that a Vienna, Austria, firm has Banca tin practically cornered.

Market Reports

LOCAL METAL PRICES

San Francisco, February 6.

Antimony	12—12½c	Quicksilver (flask)	39
Electrolytic Copper	18—18½c	Tin	53½—54c
Pig Lead	4 60—5.55c	Spelter	8¼—8¾c

Zinc dust, 1400 lb. casks, per 100 lb., small lots $9.50—9.75; large $7.50—8.50

METAL PRICES

(By wire from New York.)

NEW YORK, February 5.—Copper prices are decidedly unsettled. Lead is quiet and firm. Spelter remains weak. Average daily prices for the past week, in cents per pound, based on wholesale transactions, standard brands, are given below.

Date.	Electrolytic Copper.	Lead.	Spelter. St. Louis	Silver, per oz.
Jan. 30	15.90	4.33	6.50	62

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

B. B. THAYER is at Butte.

JAMES DOUGLAS is in Arizona.

J. PARKE CHANNING is at Miami.

R. G. HALL is at Salt Lake City.

E. G. THOMAS has gone to Mexico.

R. G. WALKER is in San Francisco.

PAUL RINK is here from Ketchikan.

A. J. MCDONALD is here from Manila.

THOMAS KEARNS is at the St. Francis.

E. G. SPILSBURY is at Houston, Texas.

C. A. RODEGERDTS has returned from Peru.

J. V. N. DORR is visiting the Panama Canal.

WILLIAM WRAITH has gone East for a brief visit.

W. H. BLACKBURN was in San Francisco last week.

EDMUND JUESSEN was in Calaveras county last week.

W. L. CREDEN is now consulting engineer for the Davis-Daly.

J. C. NILON, of Nevada City, was in San Francisco recently.

F. H. BOSTWICK has been in Arizona and California recently.

L. H. DUSCHAK is now chemist for the Bureau of Mines at San Francisco.

GEORGE E. VIGOUROUX is now with Trippe & Co., 25 Broad street, New York.

A. F. DIXON is now with the Caribbean Petroleum Co., Caracas, Venezuela.

D. D. MUIR, JR., was in San Francisco and has gone to Rochester, Nevada.

H. C. BELLINGER was in San Francisco and has gone to Spokane on his way East.

R. G. THOMAS is making an examination of mining properties near Hillside, New Mexico.

CALVERT WILSON was in San Francisco during the week and has returned to Los Angeles.

E. C. ENGELHARDT is now superintendent of the Idaho Smelting & Mining Co., Clayton, Idaho.

UTLEY WEDGE was in San Francisco and has gone to Seattle, expecting to return in about ten days.

Obituary

C. H. THOMAS died at Tuolumne, California, on January 8, aged 74. He was born in England and his first mining experience was in South and Central America. Coming to California, he engaged in mining in Amador and Placer counties, and was for many years superintendent of the Dead Horse mine.

ARTHUR CROZIER CLAUDET has joined the miners who have 'crossed the divide.' He was educated privately, and after three years experience in the alkali industry and the hydrometallurgy of copper and silver, in 1881 he associated himself with his father in London, where he continued in consulting practice for over thirty years. Besides notable achievements in the art of metallurgy he was prominent in public work, being a founder and trustee of the Institution of Mining and Metallurgy and serving as editor of its *Transactions* since 1895. He also took a prominent part in the reorganization of the Royal School of Mines, serving on the sub-committee of the Board of Education and on the building committee of the School of Mines. Perhaps his greatest service was in the way of establishing scholarships for worthy students and securing positions for them after graduation. He was always generous in his help to poorer men and will be sincerely mourned.

Company Reports

KALGURLI GOLD MINES, LTD.

This company has a capital of only $576,000, and is one of the important and most profitable of companies operating at Kalgoorlie, Western Australia. To date the mine has produced 1,092,605 tons of ore, yielding $14,848,570, and has paid $6,012,000 in dividends, of which 123,800 tons yielding $1,207,820 was produced in the year ended July 31, 1912, and $460,800 was paid in dividends. The year 1906-7 was the best from all points of view. Since then the lower levels of the mine have not opened satisfactorily, and the past year's output is $500,000 lower than the year mentioned.

During the past year ore was extracted from 18 levels, the greatest tonnages coming from No. 4, 12, 14, and 1, in the order given, the average value being $10.40 per ton, at a cost of $2.12 per ton. On No. 1 level the south orebody has been mined to its payable limits, which cover a length of 150 ft., and average width of 30 ft. Over 95 ft. the average grade is $7, falling to $6 per ton in end-sections. Diamond-drilling has given good results. On No. 2 level a westerly cross-cut was ppt out 163 ft., and at 147 ft., 5 ft. of ore worth $30 per ton was cut. North and south drifts were driven 37 and 113 ft. respectively, opening ore of good average value. Development on the 1250-ft. level proved ore over a length of 55 ft., and width of 30 ft., averaging $22 per ton. The main north drift off the main west cross-cut on the 1450-ft. level was extended from 163 to 246 ft., opening 8 ft. of $6, 5 ft. of $10, 6 ft. of $25, 4 ft. of $9, 6 ft. of $35, 7 ft. of $7, 7 ft. of $28, 8 ft. of $10, 7 ft. of $13, and 25 ft. of $3 to $5 ore, the average stoping width being 6 ft. The ore-shoot opened during the previous year on the 1750-ft. level has been further proved to cover an area of 33 ft. north and south, and 62 ft. east and west, the value on the eastern side being $11 per ton. At other points on this level there are large quantities of rock just unpayable. On the deepest level, 1850 ft., the main south drift was continued to a distance of 784 ft. from the west cross-cut, and 70 ft. from the Associated boundary. The shoot opened from 169 ft. south, proved to be 25 ft. long, 20 ft. wide, and worth $15 per ton. Raising and winzing did not open any good ore. A shrinkage stope has been carried to a height of 50 ft. above the level, the area at that height being 27 by 37 ft. To 25 ft. the value was $11, but from there to 50 ft., only $5 per ton. From observation, it is stated that possibly the ore on the 1850 and 1750-ft. levels is not of the one orebody. Thirteen holes, totaling 1638 ft., were drilled east and west, in barren calc schist and diabase rock respectively. Development covered 4083 ft.; diamond-drilling, 2108 ft.; and sample holes bored, 3294 ft. The Kalgurli mine has always been noted for the width of its orebodies, and while no close estimates of ore reserves are given, they at present approximate 250,000 tons. The report is accompanied by 13 mine plans. Extraction in the mill averaged 93.67%, against 94.75 for the previous year, the residue from $10.40 ore being 66c. per ton.

CHAMPION REEF GOLD MINING COMPANY OF INDIA, LTD.

The capital of this important company, which owns 1093 acres in the Kolar goldfields of India, is $1,248,000 in 2,080,000 shares of 60c. each, all being issued and fully paid; and during the year ended September 30, 1912, $624,000 was paid in dividends, equal to 50 per cent.

At the mine, the circular shaft had reached a depth of 3510 ft. on September 30, a depth equivalent to No. 39 level. Connection had already been made with the main workings on No. 33 level. Work on the erection of the head-frame and hoisting engines is well ahead. This shaft was sunk 476 ft. during the year, and it is estimated that at 4500 ft. the lode will be cut. Whether it will be economical to provide hoists to work to that depth remains to be proved. Only 7000 tons of ore has been stoped below No. 30 level. In Garband's section of the mine, an ore-shoot 800 ft. in length has been opened on No. 36 level, the western part of the lode being 45 in. wide, worth $15 per ton, 280 ft. of which is 9 ft. wide. This ore has been further proved south from Glen shaft on No. 37, 38, and 39 levels. On No. 41 and 42 levels, the north drifts have opened ore for 200 and 300 ft. respectively. North drift on No. 37 level from Garband shaft shows 18 in. of ore, worth $31 per ton, the total length of the shoot being 480 ft., averaging 16 inches in width, worth $36 per ton. At Glen shaft a cross-cut is being driven to the lode on No. 41 level, while on No. 39 level the last 195 ft. driven has proved 24 in. of quartz, worth $22 per ton. No. 38 level south was advanced 516 ft. in ore 18 in. wide, averaging $11 per ton, lately improving to 48 in., and $36 per ton. In Carmichael's section the shaft was sunk 255 ft., making a total of 4457 ft. on the incline. The lode still tends to dip steeper in depth, and sinking is being done at 76°, or twice as steep as some of the shafts first sunk on the field. Driving has been started on No. 44 level, where the lode is improving, it being 21 in. wide, worth $25 per ton. Northward, No. 41, 42, and 43 levels show much improvement, north drifts on the two latter levels having opened 280 and 146 ft. of ore, 24 and 27 in. wide, worth $24 an $27 per ton respectively. Ore reserves total 400,747 tons. Details of the past year's results are as follows:

Ore mined, tons	277,438
Sorted out, tons	56,828
Ore milled, tons	220,610
Stamps working	140
Gold recovered, ounces	101,173
Cyanide plant operation:	
Tailing treated, tons	167,213
Dried slime, tons	33,953
Old tailing and slime, tons	88,567
Gold recovered, ounces	29,210
Total value of gold recovered	$2,447,059
Expenditure, including London	1,385,217
Profit	912,964
Depreciation, written off shafts, etc.	176,539
Added to reserve	72,000
Total reserve fund	144,000
Cost of operation:	Per ton.
Mining	$2.80
Development	1.50
Milling	0.54
Treatment	0.56
Repairs	0.12
	$5.52
Total cost, including London expenses, etc.	$6.28

During September the new slime plant was started. The total production of the mine to date is approximately $48,000,000.

GAIKA GOLD MINING CO., LTD.

This company owns 229 claims in the Sebakwe district of Matabeleland, Rhodesia, and has an authorized capital of $1,440,000. Treatment commenced in Augnst 1905 with a 5-stamp mill, Chilean, and Huntington mill, and cyanide plant. During the year ended June 30, 1912, there was treated 34,243 tons of ore yielding $325,000. The profit was $120,000, out of which $66,000 was paid in a dividend of 5%, the remainder being carried forward. The mine is being developed with satisfactory results, and the reserves stand at 57,755 tons of ore averaging $15 per ton. The water-supply has been adequate for all requirements during the year, and improvements in equipment will effect considerable economy.

The following figures of German consumption of foreign copper for the months January to November 1912, are given by L. Vogelstein & Co.: Imports of copper were 191,993 tons; exports, 9050; and consumption, 182,943, as compared with consumption during the same period in 1911 of 168,096 tons. Of this quantity 166,307 tons was imported from the United States.

Book Reviews

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

CAMBRIAN BRACHIOPODA. By Charles D. Walcott. Part I, text, 872 pp., ill. Part II, plates, 373 pp., 104 plates. Monograph LI, U. S. Geol. Surv. Government Printing Office, Washington, D. C.

The two volumes of this scholarly monograph represent the work of a decade by the former Director of the United States Geological Survey, who is now secretary of the Smithsonian Institution. The description covers 477 species and 59 varieties of Cambrian brachiopods and 42 species and 1 variety of Ordovician brachiopods. The monograph consists of two volumes, one containing principally the text, the other containing figures of fossils. The text (part I) covers 872 pages and contains 76 text figures; the plates (part II) comprise half-tone views of more than 450 fossils, the entire work including illustrations showing 538 forms. The work includes tables of synonymy and statement showing the places and horizons at which the fossils were found. The author writes: "My main purpose has been to make the results of the investigation of value to the student of Cambrian faunas and to the stratigraphic geologist."

ESSENTIALS OF ELECTRICITY. By W. H. Timbie. 271 pp., ill. John Wiley & Sons, New York, 1912. For sale by the *Mining and Scientific Press*. Price $1.25 net.

This little book is primarily intended for the use of students in electrical trades, and therefore contains only the more essential facts and principles, which are clearly and logically presented. The steps by which the transition is made from one concept to another have been so shortened and connected that the book will not only admirably serve the purpose for which it is intended, but may well serve as a text for the general reader. The universal use of electrical equipment, for domestic as well as industrial purposes, makes it desirable for everyone to have some understanding at least of the subject. Those who have attempted to 'read up' on the subject of applied electricity, only to become discouraged by its complexities will regard this little handbook as a treasure. The simple exposition given of gas-engine ignition will especially appeal to automobile users, while such topics as electric switches, signs, and annunciators are of general interest. Each chapter concludes with a brief summary of its important features.

MINERALOGY. AN INTRODUCTION TO THE THEORETICAL AND PRACTICAL STUDY OF MINERALS. By A. H. Phillips. 699 pp., ill. The MacMillan Co., New York, 1912. For sale by the *Mining and Scientific Press*. Price $3.75 net.

This is an excellent addition to the number of good mineralogies for students which are available. Methods of study have developed rapidly in the past two decades, and the good photographic illustrations, many of them of thin sections or polished specimens, indicate at once the excellence of this volume and the reasons which made the preparation desirable. If any criticism may be made, it is that a 700-page 'introduction' is apt to appal the beginner, who has no means of distinguishing between what is important and what is not, and too frequently obtains but little aid from his instructors. Mineralogy, on the other hand, is not circumscribed by political boundaries, and it would have been better to discuss the occurrence of minerals more from a cosmopolitan standpoint. Crystallography and determinative mineralogy are well covered. Part II, descriptive mineralogy, includes 225 species of the more important and common minerals and is introduced by three chapters covering the chemistry of minerals, their origin, and physical characteristics that will be especially useful in conveying a general grasp of the subject such as the student is commonly unable to obtain from the study of individual species.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

PHOSPHATE LEASE—CONSTRUCTION

A ten-year phosphate lease with $1 consideration, $5 per year rental, and 25c. per ton royalty on all phosphate mined, was held to imply that the lessees should commence work within a reasonable time and continue operations with reasonable diligence, or failing so to do, the lessor might declare the lease forfeit.

Killebrew *v.* Murray, (Kentucky) 151 Southwestern, 662.

COAL MINE—UNINTENTIONAL TRESPASS

The measure of damages for coal taken from another's land through an honest mistake is the value of the coal taken as it lay in the mine, or the usual reasonable royalty paid for the right of mining; the 'royalty' being the price paid for coal as it lies in the earth.

Burke Hollow Coal Co. *v.* Lawson, (Kentucky) 151 Southwestern, 657. (Dec. 20, 1912.)

PLACER LOCATIONS—DISCOVERY LACKING

Where placer locations have been made within a forest reserve with the apparent sole purpose of protecting a water right as a speculative venture, and the locators were ousted by other parties who, ignoring the pretended claims, obtained permission from the Government, and went ahead with surveys, improvements, and development in good faith, it appearing that no discovery had been made or assessment work done to support the placer location, the locators thereof were denied relief.

Spokane Portland Cement Co. *v.* Larson (Washington), 128 Pacific, 641. December 14, 1912.

MINING TRESPASS—HELD NOT COMMITTED

In an action for damages and an injunction, it was held that the findings of the trial court that plaintiff's quartz claim overlapped defendant's placer location, that plaintiff had made no discovery sufficient to support his location, and that most of the assessment work had been done on the placer claim, were supported by the evidence, and that on the basis of such findings, judgment was properly given for defendant.

Olaine *v.* McGraw, 45 California Decisions, 23. January 2, 1913.

DEPARTMENTAL GAS LEASE—ASSIGNMENT

A departmental oil and gas lease was executed by a citizen of the Cherokee nation to a lessee who thereafter assigned the same with the approval of the Secretary of the Interior, but without the consent of the lessor, to defendants, who immediately entered into possession, expended considerable money, and developed a gas well. The lessor was notified of the assignment and accepted rentals and royalties under the lease for several years. Held that her conduct estopped her from asserting any rights under a clause in the lease prohibiting assignment without lessor's consent.

Scott *v.* Signal Oil Co. (Oklahoma), 128 Pacific, 694. December 3, 1912.

MINING CONTRACT—FORFEITURE UPHELD

Where under a mining contract the purchaser was to have possession of the mine and pay 10% of the proceeds of clean-ups as royalty to apply on the purchase price, and defaulted in the payment of such royalties at the time they were due, the seller was entitled to rely on the terms of the contract and claim a forfeiture. The tender by the purchaser after he was in default of the amount of the royalties at the time the vendors demanded possession of the mine would not excuse the non-performance prior to that date, and the vendors need not accept the tender.

Champion Gold Mining Co. *v.* The Champion Mines (California), November 20, 1912. (Not yet reported.)

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

OIL should not be used on rawhide pinions, but the application of a little flake graphite is harmless to the teeth.

GOLD exported from North Island of New Zealand is subject to a duty of 54c. per oz., and that from the South Island, 6c. per oz. This is on gold produced.

CONCENTRATION of dissolved metals in slime-ponds has been noted at El Tigre, Sonora, Mexico, when sampling the face of a residue dam, the upper layers assaying 6.5 oz. of silver per ton, the usual tailing being only about 2 oz. per ton.

CONCENTRATE produced from the seven mills treating Tonopah ore amounts to about 300 tons per month, which will average over 500 oz. of silver per ton. Experiments have shown that fine grinding, fresh strong cyanide solution, and long agitation will extract a high percentage of bullion; but the consumption of cyanide is nearly ounce for ounce with the weight of silver, and solutions become very foul.

COAL now bought by the United States Government is purchased under the general technical supervision of the Bureau of Mines. The cost of purchases under specifications prepared by the bureau for the use of the government now aggregates over $5,000,000 per annum, and the additional fuel bought under the general advice of the bureau now totals in purchase cost some $3,000,000 per annum more, making the total value not less than $8,000,000.

MILL TAILING may be disposed of by impounding behind suitable dams, storing it in mine stopes, or sluicing it into a river, provided this method does not interfere with navigation or agricultural land. Many mills in California are situated in canyons or at places where suitable areas for the permanent storage of tailing are not obtainable, and the question of disposal is now one of importance, as farmers are demanding compensation from certain mines in Amador county.

LITHIUM belongs in the alkali group with sodium, potassium, rubidium, and caesium. It is a soft silver-colored metal, has a specific gravity equal to 0.5936, and atomic weight equal to 7. Its valence is one. It melts at 180°C. and vaporizes at about 1000°C. It very closely resembles sodium, potassium, rubidium, and caesium in its reactions. In the wet way it may be distinguished from K and ammonium salts in that it forms no precipitate with chloroplatinic acid (H_2PtCl_6), while, on the other hand, it forms an insoluble (Li_2CO_3) upon the addition of a carbonate, while potassium and ammonium salts do not.

MINERAL locations are to be made on mineral lands only, and the question arises, what is mineral land? Mineral land is land more valuable for its mineral contents than for any other purpose. The mere appearance of mineral is not sufficient to give the land a mineral classification, if there are not substantial and lucid reasons for believing that valuable mineral deposits may be eventually opened. Again, the absence of mineral indications will not give the land a non-mineral classification, if it is within an ore-bearing zone or in a continuation of known and proved ore-bearing formations. The extent of the mineralization required to sustain a mineral location varies with the conditions. In the case of a contest between two mineral claimants, very little evidence of mineralization may be required, whereas in a contest between an agricultural and a mineral claimant, the evidence must be more conclusive. In the latter case, while the comparative value of the land for agricultural or mining purposes determines the result, the principal and usually most weighty question is, would a prudent and experienced miner or prospector feel justified or willing to spend his labor or money in trying to develop a valuable mineral deposit on the land?

TUNGSTEN is used chiefly in making steels that will hold their temper when heated, but it is most generally known as supplying the filament of tungsten incandescent lamps. The great improvements in drawing tungsten wire, and further notable improvements in the size of the globe of the tungsten lamp, and in other mechanical details that add greatly to its efficiency, are making it encroach upon the carbon-filament lamp and the arc lamp, and it is rapidly driving from the market the tantalum lamp, which was the first good incandescent lamp having a metallic filament. Diamonds are used for dies in drawing tungsten wire. At first it did not seem possible to drill small enough holes through the diamonds to make wire sufficiently fine for lamps of small candle-power, but wire 0.0006 in. diam. can now be drawn in quantity. The total quantity of tungsten ore used for electric lights, however, amounts to only a few tons per year. New uses of tungsten, in making electric furnaces, electric contacts, and targets for Roentgen rays, have been developed, and the last two products are being actively manufactured.

SULPHURIC ACID plants at Ducktown, Tennessee, were constructed for the purpose of disposing of the objectionable fumes from the large smelters of the copper companies at that place. They use what was, until their establishment, not only wholly a waste product of the smelters, but also a menace to all the adjacent country. These acid plants have therefore produced at least three desirable results by furnishing a large supply of acid where it is most needed, by rendering valuable large supplies of sulphur hitherto worthless, and by relieving the region of the nuisance of the smelter fumes, thus making it possible to continue operating the mines and at the same time to cultivate the surrounding lands. The successful manufacture of fertilizer from rock phosphate depends in great measure on a cheap source of sulphuric acid. A plentiful and cheap supply of sulphuric acid means a cheaper and a more readily available supply of fertilizers. The greatest demand for sulphuric acid is in the fertilizer industry, the greatest supply of raw materials for this industry is found in the Southern states, and the greatest demand for fertilizers also exists in this same section. Few industries, therefore, are of more importance to the South than the manufacture of sulphuric acid.

ELECTRIC LIGHT and power plant of the Kalgoorlie municipality, population about 85,000, during the financial year ended October 31, 1912, generated 1,122,863 units, of which 827,328 units were sold, or 64%. For street lighting and other city purposes, 14% was used, while 22% was lost in accumulators, mains, and unaccounted for, the latter item being 2.6%. The use of metallic filament lamps has accounted for 69% in the decrease of current used for lighting, when compared with the previous year. There are 1906 consumers, of whom 1472 use light, 347, heat, and 87, power, the total horsepower of motors connected being 598 hp. Costs per unit are as follows:

	Cents.
Fuel, @ $3.24 per ton of wood	2.19
Water, @ $1.68 per 1000 gal	0.22
Oil	0.03
Repairs and upkeep	1.93
Sundries	0.15
Wages, generation	0.88
Wages, distribution	0.23
Management	0.65
Total cost per unit	6.28

The total revenue for the year was $88,000, and profit after paying interest on capital, new accumulator, and all expenses was $14,000. The station is equipped with two Parsons turbo-generators, aand several vertical high-speed engines, and a large accumulator plant.

Use of Explosives in Ore Mining

*In most mines it is desirable not to break the ore too fine on account of the loss in valuable material that would ensue. On the other hand, in most iron mines, and in some of the Michigan native copper mines, the only desire is to get the ore out as cheaply as possible, regardless of the expense. In the Cripple Creek district the gold is in the soft tellurides and soft sulphides. The veins and stringers are narrow and this makes it necessary to mine large quantities of waste rock. By breaking the material large most of the waste can be picked out by hand, leaving a small amount of rich fine material to be treated at a minimum cost. Therefore, in the Cripple Creek district, the comparatively slow-acting Repauno gelatin and Monobel No. 1 are used to advantage.

In the Lake Superior copper country, on the other hand, as it is impossible to shatter the native copper, most of the mines use the stronger grades of Giant and and Red Cross extra dynamites. The nitroglycerin dynamites were discarded because the fumes, combined with the heat of the lower levels, had a bad effect on the men. Some of the mines of that district have wide veins varying from 30 to 40 ft. in which the copper occurs in irregular shoots. In these the vein material is broken in large pieces by drilling flat holes, having medium burdens, in the stopes, and blasting them with Giant extra or Red Cross 30% extra dynamite, which have a slow heavy action. The miners can distinguish the rock containing copper by feeling with the hand. The coarse and fine are sent to the mill, while the waste remains in the stope for filling. Here also the value of a slow-acting explosive is apparent.

The mining of sulphide ores that require concentration before the valuable material is extracted constitutes another class of work where slow explosives with a strong heaving action is necessary. This applies in particular to sulphide copper ores and arsenical sulphides containing gold or other metals in paying quantities. With the sulphide lead ores this point is not of great importance, because fine lead ores are sintered in roasting. With the sulphide copper ores the greatest care should be taken not to have the mineral finer than is best for treatment.

In the soft hematite mines of the Lake Superior district a slow-acting explosive must be used in order to reduce the explosive costs to the lowest possible point. If an explosive, having a quick smashing action, is used in soft material, a large part of its strength is consumed in pulverizing and compressing the ore or rock immediately around the bore-hole. The underground temperatures in most of the Lake Superior iron mines are low enough to freeze ordinary nitroglycerin explosives at any time of the year. Therefore, Red Cross low freezing extra dynamite, from 20 to 40% strength, is the most used explosive.

Where the ore or rock to be blasted occurs in alternate layers of hard and soft material, a quick-acting explosive must be used. If dynamite having a slow heaving action is used under these circumstances, its strength will be largely wasted by blowing out through the soft streaks. In the selection of an explosive for underground work, the class of labor employed must not be overlooked.

For general all-round use in underground work the 'extra' grades of dynamite will be found to be the most desirable. Their fumes after blasting are not obnoxious. The cases contain the largest number of cartridges consistent with good packing, and they are the safest high explosive as regards handling. It is practically impossible to ignite the extra grades of dynamite by the side spit of cheap, damaged, or defective fuse.

Careful experiments and observations over a period of years have shown that better results can be obtained by the use of strong than weak blasting caps and electric fuses. The stronger and sharper the initial shock that explodes the dynamite, the more complete will be the detonation. This means both more work and better fumes. While the leading manufacturers of explosives recommend the use of nothing weaker than a No. 6 detonator, a large number of mining companies and tunnel contractors, after careful experiments, now use nothing weaker than No. 8 blasting caps and electric fuses which are twice as strong as the No. 6 detonators.

It is also of the very greatest importance to tamp all charges solid to the collar of the hole. Tests made at the United States Bureau of Mines testing station at Pittsburg showed that with the quickest dynamite there was 30% more force available in a tamped hole than in one where no stemming was used. Also, the analyses of gases after explosion show a material reduction in bad fumes when holes are tamped.

How Long Will a Motor Truck Last?

By R. W. Hutchinson, Jr.

One of the most interesting examples which shows more conclusively than mere claims the long life of a motor truck may be found in Washington, D. C. There is in that city in daily service of the Metropolitan Coach Co. a Mack motor bus that in a three-year period (from July 4, 1909, to December 20, 1912) had attained a mileage of 142,728. In other words, the machine has made an average of more than 47,000 miles per year, better than 128 miles per day. When it is remembered that a three-ton motor truck in constant service averages about 40 miles per day, or 12,000 miles per year, it will be obvious that in attaining a mileage of 142,728 that this Mack bus has seen the equivalent of about 12 years of actual service in less than 3½ years of operation. That the 140,000 odd mileage of this Mack bus has not in any way affected its serviceability is proved by the statement of the manager of the Metropolitan Coach Co., S. D. Lincoln, that "our old reliable Mack is running just as if it might be good for 140,000 miles more." The only visible damage to the mechine is a rather battered appearance of the front wheel fenders. The bus is operating on an average of 19 hours per day, seven days in the week, which is certainly a rigorous test of the engine and the vital parts of the chassis.

Another interesting record comes from Wilkesbarre, Pennsylvania. In that city are three motor buses which have run from 98,000 to 175,000 miles. On June 27, 1908, a Mack enclosed bus was put in operation in Wilkesbarre. This bus ran continually until February 16, 1911. The body was destroyed by fire in the garage on that day and to all appearances the bus was useless for further service. The owner, C. M. Loveland, sold the bus to R. B. MacCallum, who decided to rebuild it. He placed it on the same route where it is in operation today. This bus, up to November 15, 1912, had made more than 175,000 miles, making 18 round trips over a 5¼-mile route, a total of over 110 miles per day. Motor-bus service is certainly one of the severest uses to which a motor truck can be put, as the machine must run on schedule time in order that patronage may be gained for its owner, and it is usually a service in which the truck is operating from 16 to 20 hours per day, allowing but little time for a machine to be overhauled and for the engine to cool. The Mack bus with a record of 175,000 miles is stated by the owner to have been out of commission but two weeks during 1912, and only then for overhauling.

Another example of the lasting qualities and reliability of a motor truck is that of a Saurer truck built in 1900 by Adolph Arbon, Switzerland. The International Motor Co., American builders of the Saurer truck, claim that this 12-year-old Saurer is in hard service today delivering embroidery machinery between Arbon, the centre of Mr. Saurer's large embroidery industry, and St. Gall and St. Bernice, large embroidery manufacturing centres. The photograph of this Swiss Saurer truck shows that the Saurer machines built in this earlier day differed but little from the lines of the machines constructed today. This particular truck has been operating in the neighborhood of 225,000 miles, and with the exception of annual overhauling it is as it was originally built nearly thirteen years ago.

TABLE OF CONTENTS

EDITORIAL

WORLD-WIDE regret is awakened by the loss of the explorers who sought the South Pole.

AUTOMOBILE passenger service has been started between Blagovesehenk and Tsitsihar in northern Manchuria. Apparently the East is learning to hustle itself.

ANOTHER of our contemporaries has adopted the two-column page and ten-point type. We congratulate the *Mining and Engineering World* on the greatly improved appearance of its pages.

POSSIBLE impending tariff changes give interest to the observation that although this is a high-tariff country, enormous quantities of merchandise are brought in duty free, the total last year being valued at practically a billion dollars. Chief among these commodities are coffee, hides and skins, rubber, raw silk, tin, copper, tea, and a great variety of food products and raw materials of industry which cannot be produced at home. It is interesting to note that works of art, on which the import duty was recently removed, valued at $60,000,000, were imported last year.

SALE of a Stock Exchange seat in New York for $48,000, just one-half the price reached in 1909, fills Wall Street with gloom, and there are many guesses as to whether the lean years are to continue indefinitely. No one can fail to have noticed the large increase in business on the part of stock and bond houses dealing directly with the people, which has marked recent history. It seems to have been found more expensive "to make a market" than to peddle stock direct. There are advantages, as there are also dangers to the public, in either method of marketing securities. It is impossible to say which lends itself more easily to abuse, and it is the abuse, rather than the system itself, that destroys public confidence.

MOSQUITOES have come to occupy a place in the calculations of engineers out of all proportion to their size, and around the mosquito as a medium for the transmission of disease has grown up a whole new body of sanitary science. As engineering is but the application of science to the accomplishment of useful work, the engineer must always keep in close touch with advances made in scientific research, and none have valued more highly the work of physicians in combating contagious diseases than have the engineers. It is a long road from the crude empiricism of the South American Indians who considered mosquitoes to be evil spirits which have climbed up from

the swamps along the rainbow that they might annoy and injure mankind, to such a knowledge of the insect as is reflected in Dr. H. G. F. Spurrell's scholarly article, of which we print the first part this week. It is rare that a physician has the gift of making technical matters clear to laymen, and Dr. Spurrell's ability in that direction is evident. Mining engineers, who must travel to the far places of the earth and accomplish results against many difficulties, will, we are sure, be especially grateful for this article.

RAILWAY transportation is of first importance if Alaska is to be developed. If the latter is worth doing, the problem of railway building must be squarely faced. The Alaska Railway Commission reports that under private ownership it will be necessary to charge 7 cents per mile for passengers and 8 cents per ton-mile for freight. It also reports that these rates are at least 2 cents higher than the maximum under which traffic can be expected to move freely. Government aid in some form is inevitable unless the interior of the country is to be abandoned. It becomes distinctly a question of what is most worth while. The commission is unanimous in recommending construction of 733 miles of road, to cost $35,000,000, one line serving to connect Fairbanks, Cordova, and the Bering River coalfields, and the other Seward, the Kuskokwim, and the Matanuska fields. The amount asked is a small sum to pay for even the potential development of so large a territory. It is to be remembered that every Western state was developed by railroads built by government aid. If, as the public seems to have decided, the old basis of government aid was bad, a new one should be found. No reason exists for discriminating against Alaska, and we believe that the people of the United States, when they understand the situation, will not hesitate in choosing between building a government road or abandoning the territory.

ALIEN ownership of land is limited in a number of states. This is especially true in the Middle West where there was once great fear of the establishment of a big estate system with absentee English landlords. According to United States mining laws an alien may not patent a mineral claim, though there are no restrictions on purchase of claims located or patented by others. In British Guiana it has recently been proposed to prohibit ownership of mining claims even by companies having foreign shareholders, unless the latter be in minority, and in California it has been proposed to exclude foreign corporations from any land ownership. At one time the Japanese, to bring pressure upon the foreign governments for revision of the treaties granting extra-territorial rights to the latter, refused to allow any alien to own land. When the treaties were revised this obnoxious rule was rescinded. Now foreigners are allowed to purchase lands, but foreign mining companies must operate through local companies organized under Japanese laws and having a majority of local directors. This provision is similar to the Texas law regarding railroads which, in order to assure supremacy of the state in rate regulation, requires operation of all railways by local companies. It is a sound principle that each political entity should retain the right to control industry within its territory, but any state that in order to do this shuts out foreign capital must prepare itself at once for reprisals and for slow development. It is a matter of policy, not of right.

Progress in Chemical Research

Research in the profounder depths of chemical science is constantly bringing forth results which render the world of industry its debtor. The field of work is so wide, however, that the beneficiary does not always know of what is being done in his interest, and it is desirable, therefore, to summarize at frequent intervals the results which have been attained. Such a summary of recent work in inorganic chemistry has been so admirably made by Mr. James L. Howe, professor of chemistry in Washington and Lee University, that we reproduce below, largely in his own words, those matters of greatest interest to the geologist and chemist. Data of geochemistry are difficult to obtain, and the study of the metamorphosis of minerals has been largely theoretical, more especially as to the effect of high pressures. An experimental study of their possible effects has been made by Spezia, in Turin, who found that by using pressures of 6000 to 9500 atmospheres, corresponding to depths of 12 to 20 miles, and in some cases continuing the pressure for several months, no instance of chemical action could be found. No action took place between silica and calcite, indicating no silicification. Alabaster, alum, and limonite, embedded in pulverized quartz for eight months at a uniform pressure of 8000 atmospheres, showed no loss of water. The great difference between the action of heat and of pressure was shown by the fact that goethite, heated in water to 330 degrees for seven days, became anhydrous, while it remained unchanged under 9500 atmospheres pressure continued for twenty-six days. To test reduction, copper oxide was kept in contact with magnesium and then with potassium for months at 9500 atmospheres pressure without change, although the sum of molecular volumes would have been decreased by a reaction; nor was calcite changed to aragonite. Bismuth was not liquefied by a pressure of 9000 atmospheres. Spezia also calls attention to the great difference in the effects of one-sided pressure and those of pressure uniform on all sides; the latter alone cannot liquefy metals or plastic substances.

Bergius, in working on reactions under pressure, found that when peat is heated in water to 250 or 350° it is charred, and from the velocity of the reactions he considers it possible to calculate the time necessary for the formation of bituminous coal in nature. His calculations place the time at seven to eight million years, which he considers agrees with geological estimates. In connection with theories as to the genesis of the diamond, it is interesting to note that Bolton has found that hydrocarbons are reduced by alkali amalgams to carbon, a part of which appears to be in the form of diamonds. Utilizing the fact that crystallizing substances have

a strong tendency to be deposited on crystals of the same substance if present, von Bolton led moist illuminating gas for four weeks through 14 per cent sodium amalgam in a tube coated with a very fine suspension of diamond powder in waterglass. The whole was kept at 100°. Under the microscope the powder was apparently amorphous, but after the experiment minute crystals were clearly visible. These showed the properties of diamonds, and while the amount did not suffice for quantitative analysis, it seems extremely probable that diamonds are thus formed by the reduction of hydrocarbons. If this be true, their occurrence in certain basic igneous rocks may be capable of a more simple explanation than has commonly been supposed.

The question as to what is the first reaction that takes place when carbon burns in oxygen has long been a subject of controversy and is of importance to metallurgists. The commonly accepted view that the initial combustion is to CO_2, which in the presence of incandescent carbon is reduced to CO, rests experimentally chiefly on the work of Lang, who found that in a slow oxygen stream carbon was oxidized at 500° almost exclusively to CO_2, while no CO_2 was reduced to CO at this temperature. The formation of some CO in a more rapid gas current Lang attributed to local heating, which did not occur in the slow current. The conclusions drawn from these and other experiments by Lang were called in question by Dixon, and his experiments and those of Baker on explosion rates seemed to show that at least in the case of gaseous carbon the formation of CO precedes that of CO_2. C. J. Baker also showed that while moist oxygen absorbed by carbon at −12° was given up as CO_2 when the carbon was heated to 100°, dry oxygen (by P_2O_5) absorbed by dry carbon at +12° was not given up till 450° and then mainly as CO, it appearing thus that CO is the first product of oxidation. Rhead and Wheeler have more recently approached the subject experimentally from the standpoint of determining the velocity of the reactions (*a*) $C + O_2 = CO_2$; (*b*) $CO_2 + C = 2CO$; (*c*) $2C + O_2 = 2CO$; and (*d*) $2CO + O_2 = 2CO_2$, at different temperatures. If it could be shown that either reaction (*a*) or reaction (*c*) proceeded at a temperature at which, under the same experimental conditions, the rates of reactions (*b*) and (*d*) were inappreciable, the problem would be solved. It was, however, not found possible to obtain a temperature at which the velocity of carbon oxidation was appreciable, where there was conclusive evidence of the primary formation of either oxide to the exclusion of the other. Some CO is produced by the oxidation of carbon at low temperatures under conditions which do not admit of its being formed by the reduction of CO_2, but on the other hand CO_2 is undoubtedly produced at low temperatures in quantity which cannot be altogether accounted for by the supposition that CO is first formed and then oxidized to CO_2. The conclusion is therefore drawn that when carbon is burned at low temperatures CO_2 and CO are produced simultaneously; one quite in accord with practically all previous experimental evidence.

Studies of the rare metals have been especially fruitful, and the production of ductile tungsten, for example, has been of immediate practical utility. Ruff and Martin have similarly endeavored to obtain purer vanadium than is now available, but without complete success, as the metal dissolves VO as well as the aluminum and carbon by which the V_2O_3 is reduced. Brunck has suggested the substitution of tantalum for platinum for a variety of purposes, since it is lighter, firmer, and cheaper, and almost equally resistant. Ductile tungsten has been suggested for similar purposes and seems to offer a good deal of promise. The volatility of the metals of the platinum group, when subjected to high temperatures, is not generally realized. Crookes has found that platinum loses ¼ per cent of its weight by heating to 1300° for 30 hours, while iridium loses 7.3 per cent when subjected to the same temperature for 22 hours. Ruthenium loses 25 per cent of its weight in 8 hours, while rhodium, the least volatile of all the group, only loses 0.13 per cent when heated to 1300° for 30 hours. An enormous amount of work has been done, of which the significance is not immediately evident, but the data of today are the basis of the practice of tomorrow, and the industrial operator is under a heavy burden of obligation to the scientist who with patient exactitude determines the principles and data which serve as guides to practice.

War in Mexico and Elsewhere

Mexican conditions continue too disturbed for safe prediction as to results. Ultimately the country will settle down to peaceful industry, but how soon was never less certain. The smelter at Chihuahua has closed because of the impossibility of obtaining a regular fuel supply, and mines that have maintained themselves in operation or which resumed within a year, are giving up the struggle. The dramatic outbreak of the past week in the City of Mexico would seem likely to force matters to a conclusion, but may fail to do so. It is to be remembered that there is a large Indian population, and except in the possession of better fire-arms the Zapatistas seem to differ little from the Apaches and Comanches who long disturbed our own Southwest. Raiding villages for cattle and women is primitive savagery, not civilized warfare, and a much smaller number of Indians kept our own army busy for years. Major military operations in Mexico are hardly likely to drag on even as long as did our own civil war, but pacification of the backward states will probably take years. It is to be remembered that despite the manly attitude of the ex-Confederates who went home to plant and rebuild, political conditions throughout our own South were anything but peaceful through a long reconstruction period. In the museum at New Orleans the visitor sees relics of the war in the streets waged between the police and those who captured and overturned the regular government years after the war had ended. Looking back on our own period of trouble, we smile. Dangerous and disastrous to our interests as is the present war in Mexico, patience and hopeful sympathy is distinctly our part.

Gold Placers in Central China

By E. C. Thurston

Gold is produced in many parts of China. Pumpelly listed 64 *hsien* in 14 provinces in which, according to Chinese books, gold is found, and doubtless this number could be increased materially. Perhaps the best known placer area in China proper is on the Yangtse above Su-choufu in Ssu-chuan. In this part of its course the Yangtse is called the Kin-sha-kiang or gold sand river. The earnings of the gold-diggers there are probably larger than elsewhere, but in general, the occupation is not lucrative. These notes relate to a few placers in the provinces of Hupeh and Hunan visited in November and December 1903.

PUMPING OUT A PROSPECT HOLE.

RAISING WATER FOR WASHING GRAVEL.

Hupeh

Hupeh province is in central China, lying mostly north of the Yangtse river. The Han river enters Hupeh from the northwest and flows east, then south, then east to Hankow, where it empties into the Yangtse. At various places along the Han from Yung-yang-fu to below I-cheng-hsien the natives wash the river gravel and sand for gold, notably, at low water, above and below I-cheng-hsien.

Just below Ming-chin-tien, and not far above I-cheng-hsien, over a hundred men were working a bar in the bed of the Han where that river is about two miles wide. They said they worked the whole year, moving to higher and probably poorer ground during high water, and working the lower sand-bars as these emerged far enough for digging. There are no hills for many miles up stream in which it is likely the gold originated, the nearest on the Han being the conglomerate hills between Lao-ho-kou and Hsiang-yang-fu. In such a wide shallow river, turning its sand over and over again and each time moving it farther down stream, it is probable that the gold came from long distances up the Han or its tributaries.

There was nothing apparent at this particular placer to distinguish it from many other sand-bars. The pebbles were principally quartz, slate, and schist. The largest pebbles seen had a maximum dimension of about 5 in. The men worked in gangs, each under a foreman, who was generally the temporary owner of the ground. The number of men in these gangs varied, but averaged about seven. The ground was divided between the gangs to their seeming satisfaction, but by what method I did not discover. They said they paid no royalty or taxes. A certain area was marked off by the foreman, and this area was worked to a depth varying with the conditions, but averaging about 6 in. and seldom exceeding a foot. There was said to be no gold at greater depth, and this was probably true as regards profitable operation. No wages were paid, but all shared in the profit, the foreman getting a larger proportion than his men.

The washing is done over a riffled contrivance consisting of two round wooden rods converging at the bottom and held together by cross-pieces at top and bottom. A flat wooden board is held in grooves in the side rods: this board is about a half-inch thick, with smooth surface near the top, 4 ft. wide at the top of the riffles and 3 ft. wide at the bottom of the riffles. The upper end of the contrivance rests on a wooden horse. The riffles are horizontal, and extend for about 4 ft. down the length of the board, about 3 riffles per inch. These dimensions vary. The illustration gives a rough idea of the contrivance.

At this place the gravel is washed as it came, not

RIFFLE-BOARD AT MING-CHIN-TIEN.

WASHING BLACK SAND, WU-TSA-TSO.

a selected layer only, as noted below. It is excavated with native iron hoes, and shoveled into a shallow circular wicker-basket with a slightly raised conical centre. The basket is placed at the head of the inclined riffle-board and supported beneath by a stick or shovel-handle. The central cone serves to distribute the gravel evenly. The riffle-worker pours water on the gravel, two or three circular twists are imparted to the basket by means of a short wooden handle fastened to it, during which the sand washes through the meshes, and one skillful turn finally tosses the coarse barren pebbles upon a pile at one side, and the basket is ready for a new load.

, The sand from the basket is washed over the riffles to the ground, leaving in the riffles the black sand containing the gold. This operation is repeated until the riffles are full, when the riffle-board is turned on edge and the black sand washed down sideways into a shallow wooden scoop 14 by 18 in. The black sand is then either panned out on the spot in a hemispherical wooden dipper about 6 in. diam., with a short handle, or taken home, washed, and rubbed by hand with mercury. The amalgam thus obtained is heated on charcoal or in an oven to drive off the mercury.

Most of the gold is fine and flaky, rarely some little nuggets the size of small peas are found. The operation of washing, though crude, is fairly efficient, and the men are very skillful at their work. Some of the tailing below a riffle-board was panned out, and, though considerable black sand was found, no gold was detected.

The daily earning per man was said to vary from 60 to 200 cash (4 to 12c.), rising exceptionally to $2. Allowing two extra shares to the foreman, the daily earnings per gang varied from 540 to 1800 cash or 34c. to $1.12. The area worked per gang per day was variously given as 175 to 275 sq. yd., which, at 6 in. average depth, gives a mean of 37 cu. yd. per gang.

The gold won is sold to buyers in Fan-ching (opposite Hsiang-yang-fu) at the rate, I was told, of 4000 cash per mace. At 16 cash per cent and 2.43 dwt. per mace this price equals $1.03 per dwt., which is obviously too high. More likely the price received was 3000 cash per mace, as at Wu-tsa-tso below I-cheng-hsien, or 79.2c. per dwt., which, if the gold was over 950 fine, gave the buyer a handsome profit. Assuming the value of the gold was 20% more than the miners received, the daily earnings per gang varied from 40c. to $1.36, and the yield of the gravel was from 1 to 4c. per cubic yard, with occasional richer patches.

While traveling up the Han river in March 1870, Baron F. F. von Richthofen visited and made notes upon a gold placer not far above I-cheng-hsien and opposite Li-kin-tien (which means 'gold digger's inn'). It was the season of low water, and the physical conditions he reported were almost identical,

WASHING CLAY FROM GRAVEL.

PANNING OUT GOLD.

except as to quantity of gravel worked daily per gang, which must vary materially, with those I noted at Ming-chin-tien; a few isolated gravel flats amid banks of sand were scraped to a depth of about six inches and washed over riffle-boards. The gold diggers at that time were said to earn 50 to 150 cash per day, 7 men averaging 15 cu. yd. per day, containing about 2½c. per cubic yard.

Von Richthofen was a keen observer, and his deductions were proved correct as often as I had opportunity to check them. Of this placer he writes:[1] "Every year the gold is exhausted by man and its supply renewed by the river; and, if it were at all possible to introduce here contrivances for working a large quantity of gravel in a short time (which is not the case),[2] cupidity would at once destroy the conditions for the yearly yield of gold. The gravel banks act on the same principle as the riffle of the Chinese, concentrating on their uneven surfaces the gold from its immensely fine and scanty distribution in the river sand, of which probably millions of tons are yearly carried over these places in the season of high water. When this subsides, the Chinese comes to reap his regular and unfailing crop." I did not visit Li-kin-tien, as it was uncertain whether work had commenced when I passed.

At Wu-tsa-tso, below I-cheng-hsien, on the Han, an inspection of the work was made by one of our party. Instead of washing the sand as it came (there were very few pebbles) it was carefully removed from a layer of black sand lying from 1 to 18 in. below the surface. This layer of black sand averaged about ¼ in. thick, though slightly more sand was washed to avoid loss. The gold was finer here than at Ming-chin-tien. One particular gang was watched and the record of their operations for one day was as follows: 1820 sq. ft. was worked, 84 cu. yd. of sand was handled, and 2.2 cu. yd. of black sand was collected and washed; 1.154 dwt. gold was obtained, which, at 92c. per dwt. (a little over 900 fine) amounted to $1.06 worth. The yield was therefore 48c. per cubic yard of black sand washed, or $1.26c. per cubic yard of sand handled (neglecting any gold in the material not washed). The method of washing was similar to that practised at Ming-chin-tien.

Hunan

In Hunan province a series of bench-gravels have been desultorily worked for centuries. Most of these gravels have been covered by later deposits of soil, those on the lower valley of the Hsiang river and Tung-ting lake being submerged at the season of high water in the Yangtse, while others bordering the smaller streams above the flood-level can be worked all the year.

Near the custom house on the river at Chung-ling-kee, about 7 miles north of Yo-chow, there is a horizontal quartz-gravel bed from a few inches to 2 ft. thick overlain by about 15 ft. of sandy red soil. This bed is only exposed at low water. A few short adits were driven into the bank, but more attention is usually paid to the beach-gravel, just below the outcrop and washed out from it during high water, which was naturally a little richer as the result of a later concentration. This deposit is probably poor, even for China, for though the water was low enough to permit work at the time of my visit in December, none was being done.

About 30 miles south of Yo-chow and 2 or 3 miles north of Kwei-yi and of the Mi-shui river there is a bench-gravel deposit under a low rolling plateau bordering a wide valley. The pebbles in the gravel are white quartz, and the overburden consists of 10 to 20 ft. of sandy soil. The workings extend for, perhaps, 3 miles along and east of the high road. Thousands of old shafts were seen, often not over 20 ft. apart, through which the gravel was brought to the surface and washed for gold. These workings were abandoned, I was told, during the Ming dynasty, several centuries ago, and were probably exhausted, for they are neglected by the present-day placer-miners who constantly pass over the ground. Probably the deposit never was rich, for the valley is wide here, and the Chinese miner has always been satisfied with scant returns.

Another small patch of ground close to the Mi-shui river and just east of the Kwei-yi had been worked and abandoned. The gravel bed here is 6 in. to 2 ft. thick, covered by about 12 ft. of soil. From this place up-stream to the town of Ping-kiang-hsien the river flows in a narrow channel between high hills, and above Ping-kiang to Chang-sur-kai very little placer mining was done.

Between Chang-sur-kai and Kin-tong the valley is from ½ to 2½ miles wide and the benches above the river are under cultivation, mostly as rice-fields. Under these fields at a depth of 12 to 18 ft. there is a gravel bed from 6 to 18 in. thick and extending about a quarter of a mile longitudinally, as indicated by the workings. The overburden is probably barren. Prospecting by trial pits is conducted until a piece of ground rich enough to warrant operation is found. Vertical pits are then sunk to the gravel bed, and drift mining on a small scale is practised. The pits are usually oblong, about 2½ by 1½ ft. in section. The gravel, from small drifts, is carried to the surface and washed in the Chinese wooden batea. Water is lifted from the river by foot-pumps to a tank where the washing is done. As the pits occupy but little space on the surface and are filled when exhausted, the land is not harmed for farming. Sometimes up to a thousand men are said to work the placers near Chang-sur, but I saw only a few hundred. The miners occupy themselves in farming and other pursuits during part of the year, and seem only to resort to mining when more lucrative work fails, though a few said they worked here the whole year.

Most of this ground is topographically suited to dredging, but the gravel bed is too thin and the grade too poor to permit profitable operation, aside from the difficulties that would probably be encountered in acquiring the necessary land.

Conclusion

From the examples of placer mining described, it will be seen that the Chinese are keen prospectors.

[1] F. F. von Richthofen, 'Letters to the Shanghai Chamber of Commerce, 1870-1872,' p. 24.

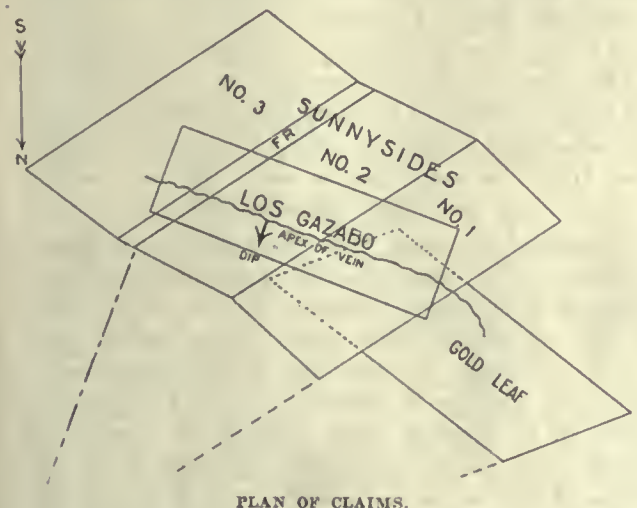
[2] Dredges were not then in use.

industrious workers, and are satisfied to earn a pittance. Gold is widely distributed throughout China, but probably in no readily accessible district in sufficient quantity and sufficiently concentrated to warrant foreign exploitation. The evidence seen during the trip in 1903 led to a conclusion precisely similar to that of von Richthofen, who traveled extensively through China and whose opinion reported to the Shanghai Chamber of Commerce in 1872 may be quoted in conclusion:

"From my own experience on the subject I have arrived at the conviction that the great number of places in which gold is washed from river-sand in China at the present day, far from furnishing a proof of the wealth of the country, is, on the contrary, clear evidence of the superabundance of human labor, the general prevalence of relatively low wages, and the poverty, individually, of those engaged in the search for gold. The gold washers of today, with probably very few local exceptions, earn less than the lowest wages which they can get for ordinary labor, and take to that occupation in those seasons only when there is the least demand for field-work. We can, therefore, safely conclude (with those few exceptions) that the greater the yield in gold, the greater will be the poverty of any one province. The sum total is, in some over-populated districts, not inconsiderable, and has quite misled the judgment of those who have even witnessed the miserable conditions of the gold diggers. The number of places in which gold occurs in the various hilly countries of Europe is probably greater, on an average, than an equal area of China: But no notice is taken of them, because nobody could be induced there to wash gold for so little return as is generally obtained in China."

The Round Mountain Case

The Supreme Court of Nevada, on January 4, filed its decision in the case of Round Mountain Mining Co. *v.* Round Mountain Sphinx Mining Co. *et al.* The case is rather a novel one, presenting the peculiar situation resulting from a single location on the one hand and a group of locations on the other, covering the same segment of vein apex, and illustrating the attempt of the owner of these conflicting locations to change the direction of the extralateral sweep flowing from this segment of vein apex by attempting to shift the previously asserted priority as between the two sets of conflicting claims.



PLAN OF CLAIMS.

The plaintiff had obtained a patent to the Los Gazabo and Sunnyside groups of claims. The Sunnyside locations conflicted in surface area with the Los Gazabo, the conflict appearing on the face of the group patent.

Defendants owned the Gold Leaf and Black Hawk claims, adjoining the Sunnyside group. The conflict arose over extralateral rights claimed by the Los Gazabo owners extending beneath the Gold Leaf and Black Hawk. If the end-lines of the Los Gazabo were to be taken as the boundaries of the extralateral plane, then the orebodies beneath the Gold Leaf and Black Hawk would be included therein. If, however, the Sunnyside claims, which lay across the Los Gazabo, were taken as the basis for the extralateral right, it would be bounded by the side-end lines of the Sunnyside group and no conflict with the Gold Leaf or Black Hawk would exist.

The Sunnyside and Los Gazabo owners, in other words, had proceeded to patent their claims so that the extralateral sweep of these claims flowing from the same segment of vein apex might be taken in either of two directions, and, as development proceeded, elected to use the Los Gazabo lines as giving the most valuable extralateral sweep on the dip of the vein. No adverse claims were filed prior to patent, and the group patent issued, showing the Sunnyside and Los Gazabo lying across each other, and the patent itself gave no light as to which claims took the conflict area. Plaintiff's contention was this was an attack on the patent which was not possible in a collateral proceeding.

The defendants, however, claimed, and their contention was sustained by the court, that inasmuch as a conflict in area was shown on the face of the patent, it was open to construction as to which one of the claims was entitled to the conflict area, because the Government cannot convey the same piece of land twice, even though it is twice described in the same patent. That it was therefore competent for the defendants to go back of the patent and determine which of the locations on which the patent was based was prior in date. That having found as a matter of fact that the Sunnyside locations were prior in date to the Los Gazabo, the Los Gazabo location was invalid as to the conflict, and hence the Sunnyside claims took this conflict area under the patent. That defendants were not estopped by their failure to adverse as to surface area because extralateral rights are not the subject of adverse claims.

The court held in substance:

"It cannot, of course, question the validity of the surface conveyed, but as the patent contains grants of distinct mining claims described by metes and bounds in conflict with each other, and controlling extralateral rights in different directions, it can insist on a determination of which particular claims the apex of the ledge belongs to, as controlling the extralateral rights."

The Habits of Mosquitoes

By H. G. F. Spurrell

*The mosquito, which was formerly regarded as a nuisance, is now considered a danger, and science devotes to its mode of life a close attention very like that with which Scotland Yard honors certain notorious and slippery criminals. The public usually receives the benefit of this careful study in the form of dogmatic assertions, that this or that must be done, or not done, for fear of something terrible happening. These injunctions, based on ascertained knowledge of the part played by insects in the transmission of disease, would probably be received with more respect, and therefore more often obeyed, if intelligible reasons for them were given at the same time. It is the hope of making these reasons plainer which has influenced me to attempt a brief review of the habits of mosquitoes.

Kinds of Mosquitoes

Upward of a thousand different species of mosquitoes are already known, and there are undoubtedly many as yet undescribed, so it will at once be seen that a composite picture of the mosquito with an account of its habits is an impossible task, and moreover, one that would not be worth achieving. It would be of no more value than a composite picture of the snake, combining all that is known of tree-snakes, burrowing snakes, water-snakes, viperine, elapine, and constricting snakes, to mention only a few of the types. Such a generalized portrait might be hailed as an inspiration by amateurs of heraldry, but it would be out of place in a natural history. The differences among mosquito types are just as great, and an attempt to generalize would be just as useless as in the case of snakes. Mosquitoes have, moreover, this also in common with snakes, that the harmless species are vastly more numerous than those which are capable of inflicting injury upon man, yet only an expert can distinguish dangerous and innocuous snakes and mosquitoes. Often even the expert can only make sure by elaborate methods: dissection in the one case and use of the compound microscope in the other. When, however, we remember that only well defined kinds of mosquitoes carry disease, and that of these, again, different kinds carry widely different diseases, we may reasonably infer that in localities where these diseases are prevalent the peculiar mosquito will be abundant. I think the habits of these few better known species, which frequent situations where they have easy access to human beings, may have enough in common to be generalized with profit. Not all these species are harmful, but it is safest to assume, according to the principles of French criminal procedure, that every mosquito is dangerous until its innocence has been established, a rule that may well be applied to snakes also.

One cannot go far wrong in saying of the mosquito that it is a feeble creature, and its habits are largely explained by its feebleness. The adult insect being weak on the wing, is an easy prey to its enemies and helpless in winds, hence it has a way of lurking in sheltered corners, and the range of its wanderings is narrow. During its larval existence, it cannot face competition in the water, hence its breeding places are often temporary puddles, too small to harbor fish or to serve as nurseries for larvae of the larger predaceous insects, like the dragon-fly.

Where Eggs are Laid

When the female mosquito is ready to deposit her eggs, she chooses a pool where the water is sheltered from the wind, and its unruffled surface is more preferred if screened from the light also. Mosquito larvae are sometimes found in streams, but when this happens the eggs have usually been laid in a stagnant backwater and among the stalks of grass on the margin. Many species of mosquitoes are to an astonishing extent independent of the quantity of water available. A collection of water not much more than a tablespoonful perhaps, caught in the hollow of a large leaf, or a hole of a tree, will sometimes be found to be swarming with mosquito larvae, and I have known a house infested with mosquitoes which I eventually traced to a lively inch of water in an old cocoa tin under the veranda.

The eggs are always deposited on the surface of the water, sometimes in 'rafts,' sometimes in clumps, and sometimes singly, according to species. At first they float. In some species each egg has air-cells to buoy it up and some eggs will not hatch if they are splashed or sunk, even if carefully dried and refloated. The eggs of other mosquitoes, notably the stegomyia, which transmits yellow fever, often, though not always, sink some hours before they hatch. Not only are the eggs of this genus uninjured by prolonged immersion and consequently liable to be washed down gutters or carried by pumps into places where the appearance of the larvae at first seems inexplicable, but they will also survive the drying up of the puddle in which they were laid, and, after long dessication, hatch when the next rains come. No generalization is possible either about the quality of the water. Some mosquitoes will flourish in a cesspool; others more fastidious prefer drinking-water cisterns and filters. At New Orleans, I have known mosquitoes to breed in distilled water when it had been left uncovered for a few days. In fact, one can only say that, wherever there is water with a calm and sheltered surface, a mosquito may be expected to deposit her eggs.

The egg usually hatches in about two days, though this depends mainly on temperature, for if kept cool enough, hatching may be delayed also indefinitely. The appearance of the larva which issues from it is only too familiar, for though at first it is very small, it unfortunately is allowed, in the majority

of cases, to grow till its structure can easily be made out with the naked eye. It feeds voraciously upon both vegetable and animal matter, its diet ranging from microscopic water plants to weaker individuals of its own kind; and the amount which it gets to eat, provided the conditions of temperature are favorable, determines the time which it takes to reach its full size. Having attained its full development, in possibly eight days, shedding its skin several times to permit of growth, it changes from the larval or caterpillar stage, to the pupa or chrysalis phase. In the former it resembles a short bristly worm with a distinct head and conspicuous eyes; in the latter there can be distinguished a large body made up of the head and parts which are to form and support the wings and legs, and a long tail, which is usually tucked under this body, the whole having a distant resemblance to a shrimp. Two points, however, both phases have in common. In both, the young mosquito breathes air and must not only visit, but spend a considerable part of its time, at the surface of the water; and in both stages it swims actively with a peculiar flickering wriggle. It is worth while for many reasons to remember that the young mosquito is continually returning to the surface to breathe, and that if the surface is not still enough for it to do this, it will drown; no less important is it to remember that when alarmed it immediately dives and lies on the bottom until the danger is past.

The pupa stage only lasts about two days, during which the creature ceases to feed and is waiting for the internal readjustment of its organs to take place. When this has been accomplished it swims to the surface, the adult emerges from the skin of the pupa, stands for a time upon it while its limbs expand and harden, and then flies off, a mature insect.

Methods of Destruction

This finishes the first half of the mosquito's life-cycle, and at this stage it may be convenient to consider how far a knowledge of its history suggests methods for its destruction. It is at once obvious that the breeding habits of the mosquito lay it open to attack in many ways. Often it is easy to dry up its breeding places altogether, and where this is impossible much may be done to prevent the mosquitoes developing in them.

Taking these two lines of attack in order, the first thing to do is to clear vegetation. The exuberant vegetation of tropical countries holds water, hides water, and shelters water. Not only do the large leaves and axillae of tropical plants often catch and hold collections of water, small but quite enough for mosquitoes to breed in, but the rapid growth and decay of tropical plants means vegetable rubbish which acts, during the heavy and continuous rains of the wet season, like an array of saucers. The paupau tree will serve as an example as well as any. It grows rapidly and soon dies, and its soft stem breaks or is cut down, leaving a stump with a top like a deep basin. Often in the course of its growth it throws out branches which get broken off, leaving cup-like hollows, in which mosquitoes breed, while the main stem is still alive and bearing useful fruit. Not long ago in West Africa I found innumerable mosquito larvae in the cup of a broken branch springing from a tree whose leaves brushed the walls of a bungalow.

When vegetation is cleared anywhere in the immediate neighborhood of human habitation, the ground is found littered with old tins and broken bottles. No power on earth will keep native servants from throwing such things where they cannot be seen, and the only way of ensuring that old tins and their inevitable complement, mosquito larvae, shall not be found within a certain distance of a house is to clear the ground round it of any vegetation which can conceal them.

Experiments have been made in the way of placing scented plants in the ground which has been cleared of its native weeds, but the hope that mosquitoes could be discouraged in this way has usually been disappointed.

Draining Pools

The next step is to drain the surface water from the neighborhood, and in doing this mistakes can easily be made by those whose intentions are excellent. Wide sheets of water, running streams, and deep ditches that are always full, do not, as a rule, lend themselves well to the requirements of the mosquito, provided that the margins are not allowed to form weedy shallows. A common error is to drain large open ponds where hungry myriads of small fish and aquatic insects keep the feeble mosquito brood from developing, and to leave in their place innumerable small puddles in which mosquito larvae alone can thrive. Draining is desirable wherever it can be done effectively; but where this is impossible, flooding is almost as good and much better than incomplete drainage. A large body of water, whether in a water-butt or a lake, can be made useless to mosquitoes by means of kerosene. A little kerosene poured on the surface will spread out until it has covered the whole with an exceedingly thin film through which the mosquito larvae are unable to reach the air when they come up to breathe, and upon which the female mosquito will not deposit her eggs. Kerosene is very valuable where it can be satisfactorily applied; but one cannot spend one's life in apportioning one drop of kerosene to every few drops of water which has been caught in the hollow of a leaf or is left as a puddle on the ground after rain.

It was, I think, in the West Indies that the stocking of all streams and ponds with a tiny fish popularly known as 'millions' was first systematically carried out. Up to a certain point the 'millions' have been a success. They feed voraciously upon mosquito larvae, but obviously they cannot find their way into the temporary puddles where eggs are deposited by the winged insect, and they have, besides, certain idiosynerasies which restrict their usefulness. In many laboratories today, experiments are being made with a view to discovering or breeding a strain of small fish which will not object to living in iron cisterns as well as natural pools and streams, nor be too fastidious regarding the depth and quality of the water into which they are intro-

duced. If these attempts at cultivation are successful, the fish will doubtless be distributed to all countries where mosquito-borne diseases are endemic. It is to be hoped that they will not then merely serve as food for the indigenous fishes.

Excluding Mosquitoes

Precautions to be taken about the house seem at first sight obvious enough. Anyone can pour kerosene on large bodies of water; no man in his senses will tolerate a litter of old tins and broken bottles near the place where he lives; and the practice of planting bottles in cement on the top of walls and breaking them with a hammer when the cement has set, which was once popular in the West Indies, has been superseded by more rational methods of fortification. The management of gutters, and the covering of rain-water tanks and cisterns, are mere matters of care and common sense; but unfortunately care and common sense, as a rule, stop short where negro servants take up the management of water or anything else.

It was in the West Indies that a medical practitioner gave me my first demonstration, and a few weks later I was applying his lessons in Louisiana. Certain rooms in a house remained infested with mosquitoes, in spite of every precaution which had been taken to exclude them. The householder scorned the possibility that mosquitoes bred in the bath-can and toilet jug: they were emptied and filled afresh every day; yet the larvae were found in both. The explanation was simple. It is the habit of mosquito larvae and pupae to dive and lie on the bottom when they are alarmed, as they naturally would be when the servant picked up the jug or can; and it was the habit of the servants to empty the vessels carelessly, leaving a few dregs, and in them all the mosquito larvae, behind in each; so that after they had been refilled their population remained precisely as before.

Feeding Habits

The mosquito, whose life history has so far been traced from the egg to maturity, is a feeble insect, and, like most feeble creatures, unless endowed with special facilities for concealment, is a rapid breeder. If it were not, it would have become extinct long ago. A female mosquito is ready to deposit her first batch of eggs by the time she is ten days out from her water existence, and she lays eggs by hundreds at a time. As she repeats this exploit at intervals during a life which may last for months, a pair of mosquitoes in the spring represents, potentially, millions of mosquitoes in the following autumn. But in order to accomplish a task involving such a drain upon the system, the female mosquito must live well. Her ordinary food, and the sole diet of the males of all except a very few species, is vegetable, consisting of the juices which can be sucked out of soft plants and fruit.[1] To support her in her duty to her species, however, she requires feeds of blood, which not only man, but other animals, birds, reptiles, and even insects are called on to supply.

The males of most species are exclusively vegetarian, and in many species both sexes subsist entirely on plant juices; but though there are exceptions in which the male takes blood as well as the female, I do not think any kind of mosquito is known in which he takes blood and she does not.

When a mosquito intends to bite she settles on the part she means to attack. This in man is most often the wrist or ankle. She then drives the piercing and sucking organs of her complicated proboscis into the skin, while the sheath-like lower 'lip' doubles back in a loop to let them project beyond it. Through one small tube the mosquito sucks the blood of her prey, and through another and still smaller tube she injects her own saliva into the wound. This saliva is held to aid the mosquito in two ways: by acting as an irritant and so determining a larger flow of blood to the part, and by altering the nature of the blood in such a way as to prevent it from clotting. It causes in the victim the local inflammation which persists for some days as an irritating papule, and is so familiar to all new arrivals in a mosquito country. The bite is hardly ever felt at the time it is inflicted, and repeated inoculations of the saliva soon induce an immunity to its after-effects which is perhaps a doubtful benefit to mankind. The mosquito takes about a minute to draw in all the blood she requires, and the amount ingested is sometimes more than would be guessed by looking at her distended body; for while still sucking she will often excrete minute droplets of clear fluid, retaining the solids of the blood in a concentrated form. After finishing her meal the mosquito is too heavy to fly actively, and retires to some dark corner where she must spend three or four days in digesting before she is ready to feed again.

Choice of Victims

Many observers say that a mosquito prefers to hang about one particular place, to feed always from the same person, and to draw her subsequent meals from the near neighborhood of her first bite. These may be her preferences, but unfortunately, in practice, she often bites more than one person or we should not have to dread her as a carrier of disease. She is more regular in the time when she bites. She may feed for the first time, in her adult life, by day; but after she has once had a feed of blood, certainly after she has deposited her first batch of eggs, she feeds again only by night. In nature all processes tend toward economy. The microscopic filaria worms, which may give rise to elephantiasis, lurk in the deeper organs of the body by day, and are only found in such blood as may be drawn from the skin by the prick of a needle or the proboscis of a mosquito, during the night hours when mosquitoes are feeding.

The habits of the various species of mosquitoes differ considerably. Some affect houses, some never come near them, some live in the bush by day and come into rooms in search of food at night, and there are even exceptional species which feed by day instead of by night; but as a general rule it may be said that mosquitoes do not like light or even light colors. Early during my residence in the United States I had pointed out to me the advantage of

wearing light clothes, particularly light socks; and, when at restaurants or on a veranda at night, of choosing a chair near, but not too near, some one who was wearing black!

One may make another safe generalization by saying that mosquitoes do not like wind. It is on warm, still, cloudy nights, when there is rain in the air, that they are abroad most. At such times one may hear, preferably from within one's mosquito net, the thin piping of the blood-thirsty females. Regarding this song of the mosquitoes, I heard a well known lecturer in the United States telling his pupils that they could distinguish the voice of the anopheles, which carries malaria, from that of the culex, which does not, by its being in a lower key; and bidding them fix the fact in their memories by thinking of grand opera in which the hero is always a tenor while the villain invariably sings bass. We need not, however, feel any particular regard for the hero in this case, as, though he does not carry malaria, he may be laden with filaria or dengue.

Range of Flight

Being feeble on the wing, the mosquito does not stray far; the distance is usually given at half a mile at most, from the place where she was bred. I heard this disputed in South America on the grounds that a certain ship always swarmed with mosquitoes when she came into port, although she usually lay some distance from the shore. I noticed, however, that the mosquitoes usually arrived after the lighters had lain alongside for the two or three days which it takes to coal in that leisurely part of the world. It is even said that the mosquito prefers to deposit her eggs on the very pool in which she passed her own youth. This may be so, but her readiness to take advantage of small puddles within a few hours after rain has fallen, shows that she is not over particular upon this point. The distribution of mosquitoes on a large scale is little understood. There seems little doubt that they do occasionally travel in vast swarms, but hardly anything is known about these wholesale migrations. The wind may carry a stray mosquito for a short distance, but not multitudes of mosquitoes for great distances, although it probably affects the direction of their flight. The mosquito has such a modest opinion of its powers on the wing, that at the first breath of wind it hurriedly takes cover in any vegetation that is handy. Even the gentle draught of a punkah will, when started, often drive every mosquito in a room to settle.

It is not easy to say how long mosquitoes will live in a state of nature. They have been known to persist for weeks on ships at sea, and, when protected in cages, for experimental purposes, can be kept alive for months. In the ordinary course of things, they must succumb in enormous numbers to natural enemies, and some of these are not at first sight likely ones. For instance, in the laboratory, ants will speedily destroy mosquitoes if they can gain access to their cages. Judging by captive specimens, the expectation of life appears to be much better for the females than for the males.

(To Be Concluded.)

Wet Silver Assay

Assay of silver by the wet method is described as follows by F. A. Allen in the *Colorado School of Mines Magazine*:

A standard solution of sulpho-cyanide of ammonium is prepared by dissolving 750 mg. of the salt in one litre of water, 1 c.c. of this solution precipitates about 1 mg. of silver. To standardize it, 50 mg. of pure silver is dissolved in 5 c.c. of nitric acid and 10 of water, both free from chlorine, the red fumes are expelled by boiling, cold water added to bring up the volume to 100 c.c., 5 c.c of ferric nitrate (made by dissolving about 5 gm. of the salt in 200 c.c. water) added, and then titrated until a faint pink but permanent end color is obtained.

Another solution is made by dissolving 12.6 gm. of common salt in one litre of water. One c.c. of this solution precipitates about 0.0199 gm. of silver and is standardized as follows: Exactly 2 gm. of pure silver is dissolved in 10 c.c. nitric acid and 20 of water free from chlorine, the red fumes expelled by boiling, cooled, and exactly 100 c.c. of the salt solution added from a 'Dafert' pipette. The solution of the silver is effected in a flask of 200 c.c. capacity, which has been carefully calibrated with an ordinary 100 c.c. pipette, and has a scratch on the neck representing exactly 200.5 c.c. After adding the salt solution the flask is tightly stoppered and shaken thoroughly, pure water added, bringing the volume up to the 200.5 c.c. mark, again shaken, and the precipitate allowed to settle; 100 c.c. is now taken out, free from precipitate, by means of a pipette and after adding 5 c.c. of the ferric nitrate solution is titrated with the solution of ammonium sulpho-cyanide. The quantity of sulpho-cyanide of ammonium used is multiplied by two and its equivalent in silver is deducted from 2 gm., the difference being the quantity of silver precipitated by 100 c.c. of the salt solution. The concentration of the salt solution should be varied so that 100 c.c. precipitates a little less than the fine contents of silver contained in 2 gm. of the sample to be assayed, so that nearly all of it is precipitated by the salt, leaving only a very small amount of the silver still in solution so that the titration may be finished by the more delicate solution of sulpho-cyanide of ammonium.

In the actual assay of silver bars, 2 gm. of the granulated sample is weighed up and treated exactly as described in the standardizing of the salt solution, finishing the titration with the solution of sulpho-cyanide of ammonium, side by side with the 2 gm. of pure silver used for standardizing, so that the pink tinge at the end will have the same intensity in each case.

Mines of Bendigo in 1912 produced $3,363,000 from 353,794 tons of ore, to which lessees in 38 mines contributed 31,788 tons, worth $243,000. Dividends totaled $560,000, and assessments $750,000. In 1911 the figures were: gold output, $3,287,000; dividends, $600,000; and assessments, $800,000. To date Bendigo has yielded gold worth $375,000,000. The mines controlled by the well known Lansell family yielded 47,983 tons, worth $323,000 in 1912.

Mine Surveying

By E. A. Colburn, Jr.

Though much has been said and written about the need of accurate survey work underground in metal mines, many managers, superintendents, and operators fail to appreciate the absolute necessity for reliable stope and level maps of the workings under their supervision. Recently while making an examination in the Southwest, the following costly mistake came to my notice. It could have been prevented by a couple of hours work with a pocket transit, and may be taken as an example of the many blunders made by prospectors, and others, through the lack of any attempt at surveying, even in a crude way.

The prospector had opened some ore in a shallow

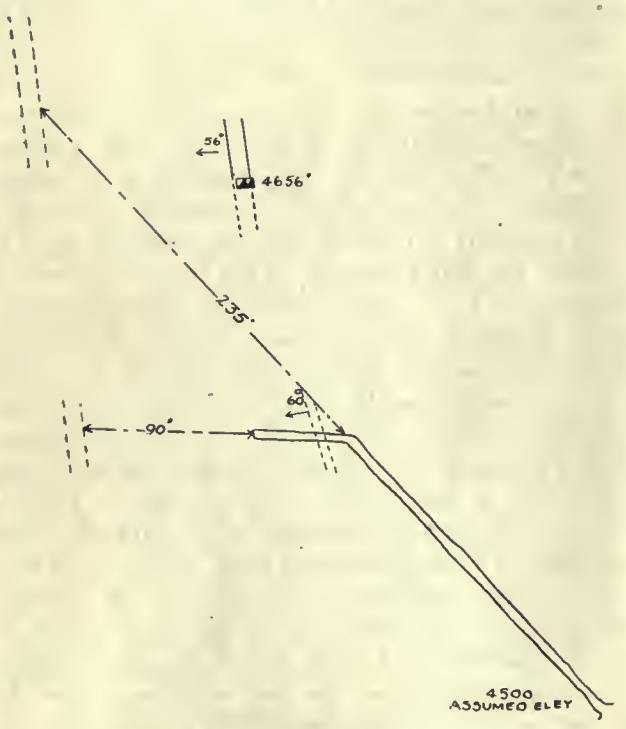


Fig. 1.

shaft (Fig. 1) on a rather steep hillside, and wished to cut the orebody at greater depth. This he tried to accomplish by driving an adit, from the hillside below the shaft, cross-cutting the formation. Why he should have preferred to cross-cut rather than drive an adit on the vein, as he could have readily done, is a question of judgment rather than of surveying, but at any rate he started his adit about 300 ft. down the hill, driving in a course about 10° to the left of his shaft in order to allow, as he supposed, for the dip of the vein.

After driving the adit nearly 200 ft. and not finding the vein, he turned to the left and cross-cut the formation for 50 ft. more in the hope of finding it. At this point his funds were exhausted and he was obliged to suspend work with 90 ft. yet to drive before reaching the vein and 130 ft. to drive on the vein in order to reach the point for which he started. Had the adit been continued upon the course on which it was started, it would have required about 430 ft. to cut the vein, though the owner of the claims had estimated that a little over 200 ft. would be sufficient to reach it. The prospector, in laying out the work, must have used a tape that was correct in about the proportion of 1½ to 1, and estimated the dip of the vein as nearly vertical; or, as is more likely, guessed at the whole thing. The loss caused by this mistake amounts to far more than the cost of the adit, as some ore might have been blocked out if the money had been expended judiciously. It is hard to believe that an engineer could make a similar mistake, but several cases of a like nature have been noted, resulting in large sums being wasted in useless work.

Managers are often to blame for conditions like this, as they prefer to employ poor men, at an average salary, rather than good ones at a slightly higher rate when the money expended through one mistake would pay the additional salary for a year or more. It is imperative that a superintendent, in charge of

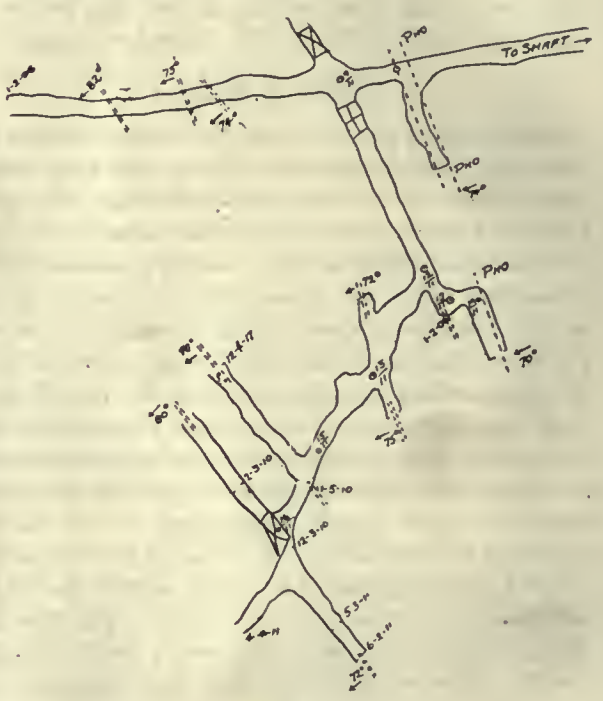

Fig. 2.

a property of any considerable size, should insist on the following things relative to his underground surveying and mapping: (1) The stope and level maps should be brought up to date at least once a month. (2) All level maps should show offsets in the drifts; all veins, dikes, faults, and changes in country rock noted in the work and give the dip of these formations. (3) Stope maps should show monthly progress, either by stipple or cross-hatching, and the average width of each section of the stope. (4) All grades in the levels should be taken and shown on the maps at frequent intervals, and all surveys should be accurate enough to be used in making connections with other levels if occasion should arise. Otherwise the additional expense of an extra survey might be required.

Monthly Surveys

All maps should be brought up to date at least once a month, as otherwise considerable money may be foolishly expended. When machines are being worked on two or three shifts and progress is rather

rapid, the services of a surveyor are often required between his regular monthly visits, especially if the work is at a critical point. A few feet of unnecessary work will pay for the services of an engineer several times over.

Geological Maps

All level maps should show the geology of the country passed through, such as dikes, faults (if recognizable), and all changes in the country rock, together with the dip and strike. This can more readily be done when offsets are taken as the survey progresses and platted to scale on the maps, not

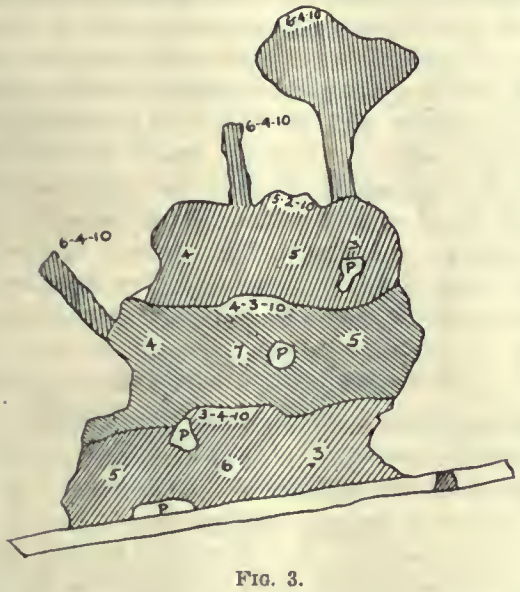

FIG. 3.

relying, as so many engineers do, upon guessing the width of the drifts and the position of the walls. The veins and streaks noted in driving levels should be sampled and the results placed upon the maps, but this is rather the work of the mine superintendent than the engineer, although at many mines surveyors check other samplers on this work.

Geological mine maps are one of the greatest helps to the manager in laying out his development work; an aid which is almost totally ignored in most mines. I have seen map after map with no geology of any nature, showing neither veins nor any change in the rock formation, most of them having only limited data as to the true position of the drift walls in respect to the survey lines. An engineer making an examination of a mine with any considerable extent of workings, and supplied with maps of this sort, must either trust to the memory of the foreman or superintendent (which is usually faulty), or work the geology out himself, which occupies valuable time better spent on other matters. Fig. 2 shows the methods in use at many mines to indicate the monthly progress, geology, and other features.

Stope Maps

Stope maps are of great assistance in finding new ore and tracing downward extensions of oreshoots, and should be kept close up to the actual work. Work done each month should be differentiated from that of the preceding and following months by a difference in the stipple or cross hatching; the day, month, and year upon which the survey was completed should be placed along the line defining the month's work. Any stopes on veins crossing or intersecting should have a separate sheet and not be placed on the main vein maps; if both stopes are placed on one sheet, the superintendent himself, after a year or so, will not know which stope is which. As an example of this, the following incident may be related.

An engineer, examining a property, asked for separate stope maps of two veins intersecting at an acute angle, both being shown upon one stope map in the company's office. After considerable delay, due to the surveyor's inability to tell which stope was which and his numerous consultations upon the matter with the mine foreman, the maps were prepared and handed to the engineer. Most of the stopes shown on the maps as being on these veins were represented underground by unstoped ground, and conversely.

The engineer should also show the average width of each section of the stope and roughly figure the tonnage mined therefrom every month. It is surprising how closely the results check with the actual tonnage at the end of the year. These tonnage estimates are especially useful in figuring the net proceeds per ton of ore mined at properties where a great deal of waste is sorted out and no record is kept of the amount of such waste. Fig. 3 shows a stope mapped in this way.

Accurate Surveys

As the surveys advance with the level work, the grades should always be taken accurately and shown on the map at every second or third station. Thus the maps show at a glance the elevation of any part of the mine with reference to any other part, and the distance between levels may be readily determined without further survey work or looking up of old survey notes. The question of accuracy in all underground surveying cannot be emphasized too strongly, as there are few engineers who will rely on their ordinary mine maps for making connections without making special surveys for this purpose. This should not be true, as the old saying, "What is worth doing at all is worth doing well," applies to the mining industry as well as to any other walk of life. The little additional time necessary to do the work well is more than compensated for by the reliability of the survey and the saving in special surveys for connections.

Conditions of temperature and pressure and the amount of moisture present determine the composition of the secondary minerals formed from others by alteration. How marked this effect may be is well illustrated by a lead pipe, recently described in *Chemische Zeitung*, which had been buried in porous cement for 24 years, and was found on examination to be surrounded by 24 red layers of Pb_3O_4, alternating with 23 yellow layers of PbO, the former having been formed in summer and the latter in winter. Careful study has similarly shown that in the case of many minerals slight differences in the temperature of formation cause marked changes in the composition of the product.

Uses of Manganese Steel

By S. R. Stone

*Manganese steel first came into prominence about twenty years ago. Although recognition of its great commercial value has not been general until recently, some of its possibilities were apparent even then, for up to that time metal hard enough to resist abrasive wear was too brittle for many applications. In the new material, however, metal workers found the then novel quality of hardness without brittleness—not the glasslike hardness of unannealed chilled cast iron, but one associated with toughness. This combination is peculiar in its resistance to cutting tools; yet the metal possesses malleability, so that while it is commercially impracticable to drill or cut manganese steel, it can be forced cold and even drawn into fine wire. It is, however, important to note that such freedom from brittleness can only be obtained when the metal is quenched after being heated to the proper temperature. If allowed to cool slowly, unless of very small section, it is entirely too brittle for useful service.

Manganese steel is used largely in the form of castings, and many of these find their applications in the rough. Where finished, to secure a smooth surface, there are two principal processes employed, namely: rough grinding and precision grinding, or 'machining,' as it is commonly called.

Crushing and Pulverizing Machinery

Manganese steel has found one of its most noteworthy uses in the construction of crushing and pulverizing machinery for rock, ores, coal, coke, matte, slag, cement clinker, or any friable material, with, however, varying success for different parts of the various types, as stated below, and these distinctions should be carefully noted. In not a few cases the exceptions are the most important to learn. For crushing rolls the roll wheels, whether solid or segmental, the side plates, gears, and pinions can be made to advantage from manganese steel. In jaw crushers the jaw and cheek plates, toggle plates, toggle bearings, and breast plates are the parts for which it is usually specified. Gyratory breakers require it for the crusher heads, mantles, concaves, spiders, hoppers, spouts, wearing plates, shaft bearings, gears, pinions, and dust caps. For mills of the Chilean type, which consist of a wet grinding pan and revolving rollers or 'mullers,' manganese steel is recommended by some for the tires, die-rings, and muller shafts; but to my mind this use is at least questionable. For the gears and pinions it undoubtedly is, however, the proper material. The same may be said of Kent mills, Kinkead mills, Huntington mills, Raymond mills, etc. For Fuller mills the yokes, pusher pins, and die-rings are recommended by prominent users to be made of manganese steel. Tube-mills do not offer much of a field for manganese alloy, except as to the screen plates used at the discharge end of certain types, the gears, and pinions; but ball-mills and comminuters show the advantage of using it for breast and wearing plates, end liners, coarse screens, shaft protectors, gears, and pinions. By some authorities such steel is recommended for a stamp-mill, including the dies, liners, and wearing plates, of steam stamps and the mortar liners, chutes, and launder liners of gravity stamps, but by others the use of chrome, vanadium, or other alloy steel is regarded as preferable.

Conveying Machinery

On bucket elevators the use of manganese castings for the buckets, chain sprockets, and pins greatly increases their wearing qualities; but for the buckets this material is relatively expensive, and chilled iron, though more frequently renewed, costs less for the year. For chutes over which rock, ore, or other heavy abrasive material is passed, including linings, deflector plates, and the like, steel containing high manganese offers exceptional wear. For the wire ropeways, manganese steel is used for the carrier wheels, sheaves, and idlers. Such parts not only wear many times longer when formed of this material than if made from any other commercially usable metal, but also give fully 25% more life to the cable.

Screening and Conveying

For heavy screens of all kinds, whether stationary, shaking, or revolving, it is ideal material, while as the lining of bins and chutes for hard rock, ore, and launders, it shows wear qualities much greater than any other material. It is also used to some extent for grates and grizzly bars, but the latter can be so readily renewed as often as necessary that old rails or chilled iron bars ordinarily serve the purpose. In revolving trommels there are not only the screens but also the tires, rollers, sprockets, and chain, gears, pinions, and feed and discharge ends, while in stationary screen plates for special service there may be unusual parts like the screen spiders and protection strips in stamp-mills, which it is desirable to manufacture from manganese steel.

One of the most useful of its applications is in the manufacture of wheels or wheel tires for mine cars and trams, skips, charging buggies, or barrows, slag cars, stripping cars, quarry cars, etc. Not only do these wheels show greatly lengthened service, but they can be made much lighter. On dump cars the use of manganese steel for ratchet wheels and levers is rapidly increasing.

Where pumps are designed for handling sand or tailing, or for gritty fluids (non-acid), the shells, liners, runners, guide vanes, as well as piping, can profitably be made of this steel. No other material, in fact, can be used without very frequent renewal.

Digging Machinery

All wearing parts of steam-shovels are now made of manganese steel, including lips, teeth, dipper fronts, latches, and latch keepers; in fact, complete dippers are now being made, every part of which, except the rivets, is of manganese steel. The life of the metal in this case is easily four times that of ordinary steel. Dredge, ditching machine, and dragline excavator parts commonly made of manganese steel are as follows: bucket lips, teeth, wearing

*Abstracted from the *Iron Age*.

plates, links, pins and bushings, tumblers and removable parts, launder liners and rollers, chute liners, sheaves, chains, sprockets and pins, revolving screen sections, tires, rollers, gears, pinions, sprockets and driving chains, knives in cutter heads, and numerous special parts. The life of a grab-bucket is greatly prolonged by the use of manganese steel for the lips, side arms, sheave wheels, pins, bushings, and to a considerable extent of the trays or leaves and shanks, each made in one piece.

Hoisting Engines

For hoisting engines manganese steel on the drums keeps them in good condition and prevents the wearing of spiral grooves; while sheaves in general for rope haulage, when made of manganese steel, not only last exceptionally long, but are so smooth that they do not hold gritty particles at all in the groove, and lengthen the life of wire ropes very materially. The initial expense, however, appears to have militated against the use of this metal for drums or sheaves of larger sizes. The case is similar with helicoid conveyor parts, such as the sectional casings and screws, gudgeons, conveyor caps, hanger casings and bushings, gears and pinions, but for the casings and screws, which have been found difficult to produce, the costs are high and chilled iron gives good results. In handling hot clinker or other heated material manganese steel will not do at all.

Around the Smelter

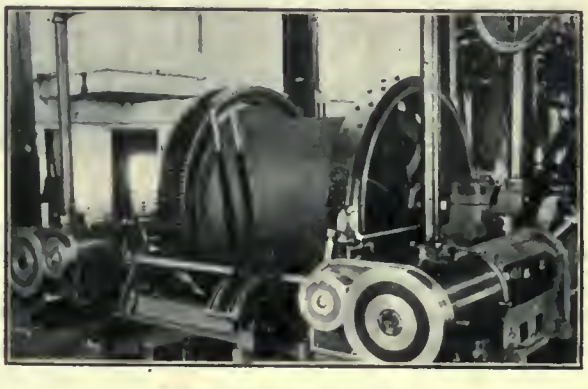
Presses handling gritty material include with benefit manganese steel plates ground on all surfaces. In the maintenance of rotary driers, sintering machines, roasters, kilns, and clinker coolers, its use for the tires and rollers, as well as gears and pinions, effects material economy, but it should not be used where it will be directly exposed to heat. For converters the claim of economy is also made, and with justice in the case of the double-flanged rollers, blank rollers, racks and sectional gears, as well as other parts.

One of the most successful uses to which manganese castings are put is for gears and pinions. In some cases the ratio of wear, compared with cast iron and carbon steel, is as high as 15 or 18 to 1. Gears of all sizes are used in large quantities, varying in weight from a few pounds to ten tons or more. As a rule, the teeth of manganese steel gears are cast rough; but manufacturers have recently been making gears with teeth ground accurately to pitch, such finish being necessary when the gears are to run at high speed. Large gears are often made with manganese steel rims and some steel centres and arms, and sometimes in halves. Gears and pinions in machinery exposed to gritty dust are particularly long-lived when made of manganese steel.

Iron smelting and iron-ore mining during the first half of 1912 made encouraging progress in South Russia, 2,247,966 short tons of cast iron being produced. This was an increase of 339,156 tons over the same period of 1911, due to the rapid building of tramways and progress made in the manufacture of machinery.

Wuest Gears for Mine Hoists

The application of the Wuest system of herringbone gears by some of the leading American manufacturers to mine hoists has directed renewed attention to this interesting type of gearing. That it is an ideal form of tooth has been well known for years, but as practically all helical gears in use prior to the advent of the Wuest system had cast teeth, the inaccuracies in casting produced so much friction in operation as to practically counteract the benefits derived from the great strength of the gearing. The excessive noise was also very annoying, and a hoist with cast helical tooth gears could create enough disturbance, when in operation, to seriously affect the peace of a whole community. The difficulty in cutting with speed and accuracy has made spurs and bevels more successful commercially than gears of the herringbone type until gears made by the Wuest method came into vogue in England about seven years ago. Since that time they have



WUEST HERRING-BONE GEARS.

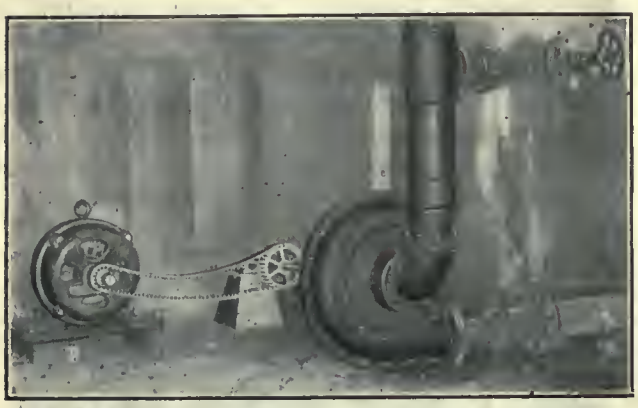
found a rapidly increasing application in the United States, and now are found in use in one form or another on all machinery where accuracy, strength, and efficiency rather than low first cost are the factors governing design. The distinction between the Wuest gears and those of the ordinary herringbone or helical type is that the teeth of the former, instead of joining at a common apex at the centre of the face, are half the pitch apart and do not meet at all. This does not affect the action of the gears, but permits their manufacture by precise methods and makes them commercially applicable to any mechanical power-transmission that permits the use of gearing. All conditions that make for ideal operation are furnished by herringbone gears, provided, of course, that they be accurately cut. The fundamental principle of the action of the herringbone teeth lies in the fact that all phases of engagement take place simultaneously. There is a tendency to concentrate the load near the pitch-line, so that the ends of the teeth, instead of wearing away to a constantly increasing extent from their original involute form, are relieved of some of their load from the moment wear commences. The destruction of the original form is practically nothing, the motion is transmitted from pinion to gear without shock, jar, or vibration. Continuity of action is the second characteristic of herringbone gears. The third feature lies in the fact that the bending stress

on the teeth does not fluctuate from maximum to minimum, as in straight gears, but always remains near the mean value. There is, therefore, no backlash; friction and mechanical losses are so small as to be barely appreciable, while higher velocities and greater degrees of speed reduction may be used than with any other kind of gearing.

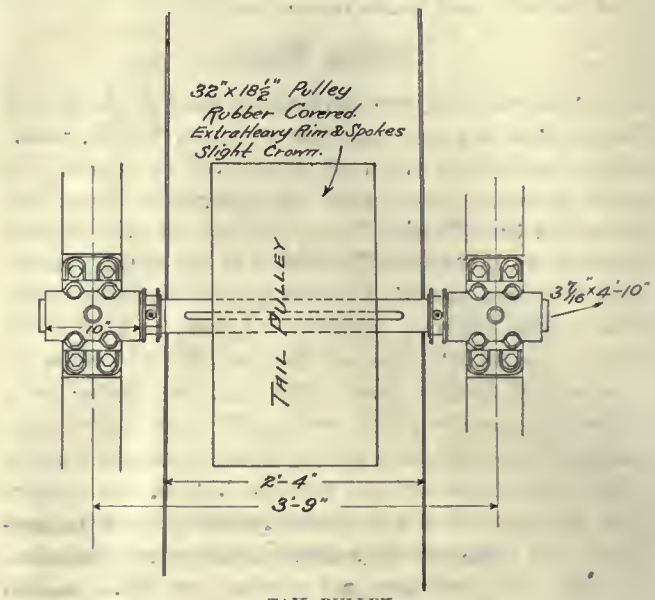
Elevating Pulp

By M. W. von Bernewitz

In Tonopah and Goldfield milling plants quite a variety of ways of elevating and circulating pulp



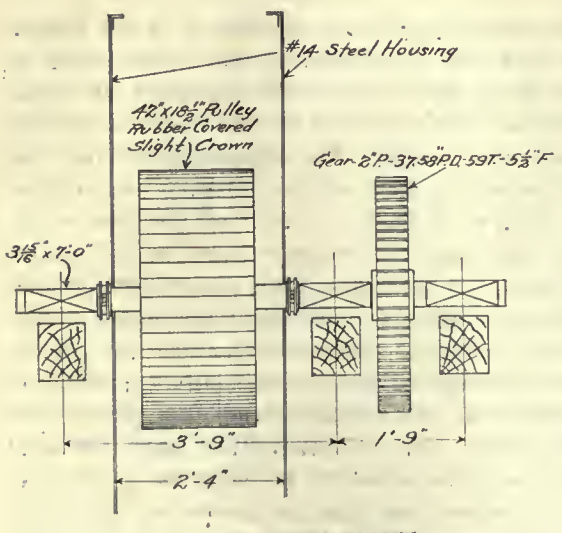
CHAIN-DRIVEN PUMP.



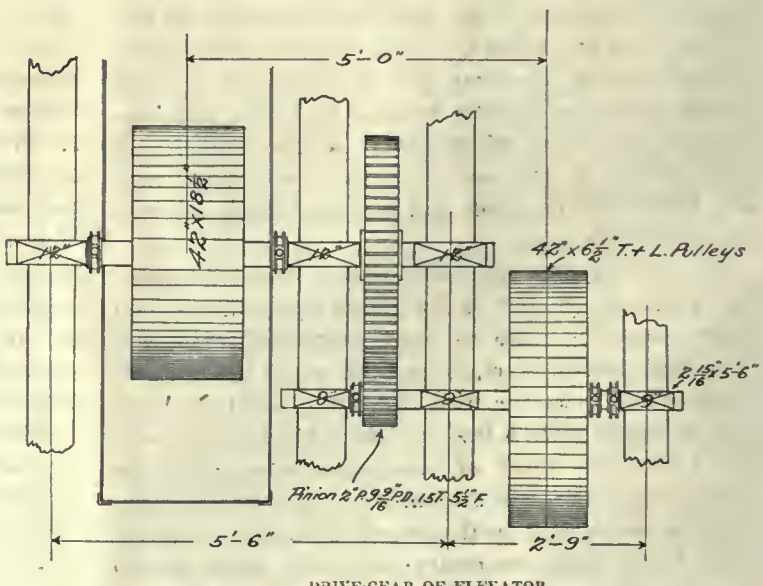
TAIL PULLEY.

are employed, and a short description of these should prove interesting, as millmen are often at a loss to decide what system to use. The new Belmont mill has three-throw plunger pumps lifting thickened pulp from No. 1 Dorr tanks to the first battery of Pachuca agitators; and from these it is elevated to the No. 2 Dorr thickeners by an air-lift. Excess from the vacuum-filter vat is returned to the stock tank by a bucket elevator with close-connected buckets. This is vertical, and part of the time is heavily loaded, but gives no trouble. At the old Belmont mill, at Millers, a tailing-wheel is used to lift pulp from the stamps a height of 48 ft. to classifiers. The up-keep of this wheel is low, and it is reliable. This plant treated 87,952 tons during the past financial year, and elevating and classifying cost about 3.6c. per ton.

From the Dorr classifier and tube-mill closed circuit in the Extension mill, slime is raised to the thickeners by a Campbell & Kelly centrifugal motor-driven pump, running at 600 r.p.m. The life of liners is from 180 to 240 days, at a cost of $35 per liner and runner. Work of this pump is most satisfactory, and it is used largely at Tonopah. It is made by the local foundry, and has attracted favorable attention. Liners are made of a special tough steel mixture, and are not cast split in the usual way, which permits pulp to cut them out rather fast. The accompanying illustration shows one of these pumps at the MacNamara mill, driven by a chain from motor, a style of drive very popular and satisfactory.

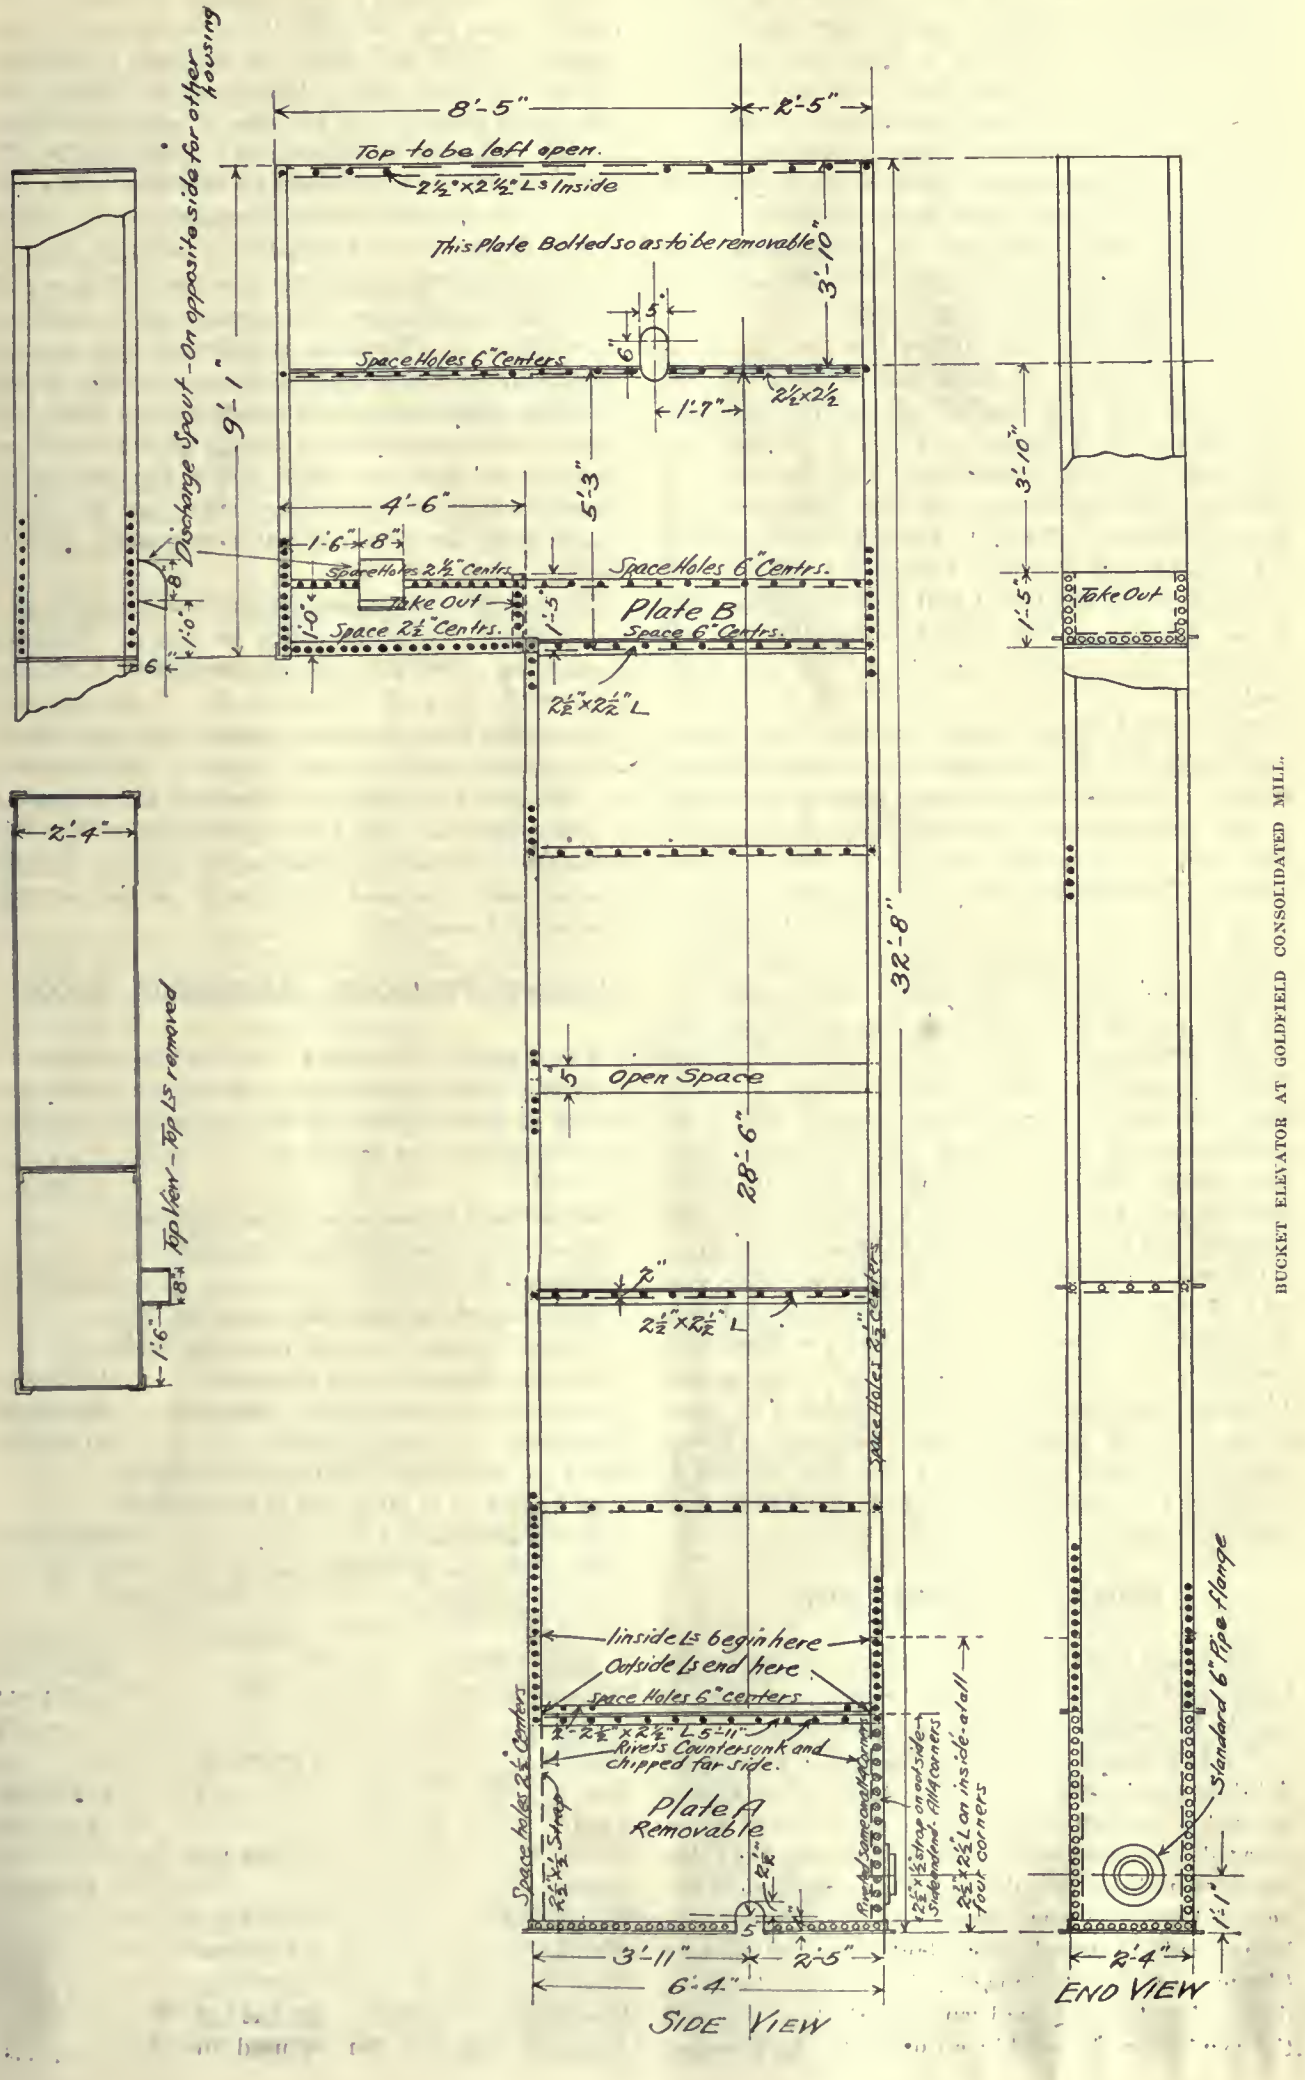


CROWN PULLEY.



DRIVE-GEAR OF ELEVATOR.

A 5-ft. Frenier spiral pump at the MacNamara lifts tube-mill pulp a height of about 12 ft. to a Dorr classifier. Its work is satisfactory. For circulating slime in the Trent agitators, 4-in. Campbell & Kelly pumps are used, driven by 7½-hp. motors, and consuming about 6 hp. At the filter vat there is another of these pumps, used for filling, return-



BUCKET ELEVATOR AT GOLDFIELD CONSOLIDATED MILL.

ing excess slime to stock tank, and circulating. It is belt-driven by a 20-hp. motor and works well. At this point, all pipes are so fitted that they will drain properly after being used, as in cold weather, at this altitude, pulp would be liable to freeze. At the Montana mill Frenier pumps give good service. In the cyanide department the 6-in. Morris centrifugal pumps, lined with manganese steel, last about 18 months. They are used for elevating all pulp to agitators from settlers, and to stock tank from agitators, and excess from filter vat.

The Tonopah mill at Millers has two wheels at work. No. 1 is 30 ft. diam. and elevates 500 tons of dry ore and 3500 tons of solution per day from the stamps. It is driven by a 7½-hp. motor. The first cost of wheels is considered high, but they are efficient, and maintenance is low compared with bucket-elevators. The cost of elevating and separating is given as 8c. per ton. Campbell & Kelly pumps are used at the West End mill for circulating slime in the Trent agitators, transferring slime to the thickener, and at the vacuum-filter; and are highly praised.

The Goldfield Consolidated has two bucket-elevators lifting pulp from Chilean and tube-mills to classifiers. Details of the gear and housing are shown in the accompanying diagrams. The elevators are each 28½ ft. from centre of tail to centre of head pulley. The housings are of steel plate, and are 28 in. wide and 76 in. long, with a total height of 32 ft. 8 in. The head pulleys are 18½ by 42 in., fitted on $3^1/_{16}$ in. by 7-ft. shafts. Spur gears have 59, and pinions 15 teeth with 2-in. pitch, and the driving pulleys are 6½ by 42 in. Tail pulleys are 18½ by 32 in., fitted on $3\ ^7/_{16}$-in. by 4-ft. 10-in. shafts. Both head and tail pulleys are lagged with 6-ply rubber belting, secured with ⅜-in. elevator bolts, 5 in. apart. Flanges or collars on the tail pulley prevent grit getting into the bearings. The belts travel at 450 ft. per minute, and the carrying capacity is about one-third of the theoretical cubic content of the buckets. The belts are Silvertown rubber make, 18 in. wide and 8 ply, and are fitted with malleable iron buckets, 8 by 8½ by 16 in., spaced 14 in. centres. Each has two ⅛-in. holes, 4 in. apart in the bottom, giving a freer discharge. Power absorbed by each elevator is 7 hp., and the life of a belt is 12 months, during which 400,000 tons of pulp is elevated, at a cost of 1.5c. per ton.

Flotation at Great Cobar

The Great Cobar company, of New South Wales, has erected a flotation plant, and at the annual meeting the following information was published:

We had hoped to have the Minerals Separation flotation plant completed in the latter part of August or September but, on account of our inability to secure sufficient mechanics without increasing the existing rates and the difficulty in securing supplies at the agreed time, this was impossible. Preparations are being made to supply the plant with 500 tons of Chesney ore, and 200 tons of Cobar banded slates per day. After the mill has been properly tuned up and the conditions thoroughly adjusted to the tonnage, which will probably be in February or March 1913, the directors may look for the achievement of that tonnage. Until that time the estimate is between 400 and 500 tons daily. We expect to derive from this source from 350 to 400 tons of copper monthly, leaving from 450 to 500 tons to be produced by the Cobar Gold and Cobar Mines by smelting. This will give an annual production of approximately 10,000 tons of copper with between 40,000 to 50,000 oz. gold, and from 200,000 to 250,000 oz. silver. In the past the Cobar mine has been the keynote of the situation. Any delays or difficulties experienced here immediately reacted on the tonnage along the entire group. With the completion of the flotation plant these conditions will be materially altered and, while still remaining the most important factor, the greatly reduced demands which will be made upon the Cobar should make the above estimates easy of accomplishment.

We have received a cablegram from Mr. Bellinger, dated December 28, in which he says: "Minerals Separation plant test-mill operated from 8:45 December 23, to 3:45 December 24, 31 hr. 50 min., yielding 400 tons jig tailing, assay 1.28 copper, result concentrates 19.35% copper, residue 0.24% copper. For the last 7½ hours, mill operated at the rate of 560 tons per 24 hr. Mr. Faul, representative Minerals Separation Company, authorizes me to state greatly pleased with plant and operation of process; success absolutely assured."

Copper Producers' Association Report

The Copper Producers' Association statement, February 8, shows an increase during the preceding month in accumulation in this country of 17,885,770 lb. The details are as follows:

	Pounds.
Stock of marketable copper of all kinds on hand at all points in the United States, January 1, 1913	105,312,582
Production of marketable copper in the United States from all domestic and foreign sources during January	143,479,625
Deliveries for consumption, January	65,210,030
Deliveries for export, January	60,383,845
Stock of marketable copper of all kinds on hand and at all points in the United States February 1	123,198,352

The changes in surplus since have been as follows, in pounds:

	Increase.	Decrease.
January, 1912	.....	22,173,252
February	.....	3,301,944
March	.....	572,431
April	2,927,829	.....
May	.....	15,450,386
June	.....	5,280,639
July	5,945,416	.....

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Mining in Porto Rico

The Editor:

Sir—In the interest of legitimate mining, I ask you to publish the following warning to the mining public. At the present time there are a number of grafters operating in Porto Rico, to the detriment of real mining; it is purely a stock-jobbing graft. I ask the mining and investing public to at least investigate before they invest. There are several good prospects in Porto Rico, but none of them are on the market now.

M. L. MURRAY.

San Juan, Porto Rico, January 28.

Concentration by Flotation

The Editor:

Sir—In compressing my article on 'Concentration by Flotation' in your issue of January 4 so as to make it occupy exactly two pages, you excised some matter which did not deserve this fact. As its omission did an unconscious injustice to the engineer to whom is due the practical success of the Minerals Separation process, Theodore J. Hoover, I should like you to reproduce the paragraph as originally written, indicating by brackets the matter omitted in the printed article:

"The discovery made by Minerals Separation was the efficacy of minute amounts of oil or analogous substances, when used to produce a froth by means of rapid agitation. The virtue of the smallness of the amount of oil was discovered by Sulman & Picard [and its successful mechanical application in combination with rapid agitation is due to Theodore J. Hoover, who, however, in his new book, gives Mr. Wolf credit for being the first to propose violent agitation]."

EDWARD WALKER.

London, January 24.

Taxation of Mining Claims

The Editor:

Sir—Authorized by an amendment to the state constitution, the Nevada legislature passed a law, which became operative this year, making $500 the taxable value of each patented mining claim in that state, irrespective of whether it contains one or twenty acres, is producing ore (if any) in large or small quantities, or of great or little value; provided, however, that if $100 worth of labor was performed on any one claim during the last year previous to that for which the tax was levied, the taxable value of such claim is reduced by the discriminatory law to $50.

The apparent object of the law in question is to 'freeze out' the absentee, and it is a very unjust one, both to corporations and individuals alike. Excepting when litigation, the settlement of estates, and other unavoidable preventives interfere, or when a company or individual has spent all the money available for exploitation, it seldom occurs that either the one or the other will abandon a mining claim if past developments justify further operation or effort.

It has frequently occurred that an individual has expended all of his money on his patented mining claims, amounting in some instances to many thousand dollars; that he has been compelled to lease them, to seek employment in other places and perhaps at other vocations, to the unavoidable neglect of his own property and in direct opposition to his own will. Is it fair that, in such a case, or in any case mentioned or parallel to it, under discriminatory taxation, the owner of a patented mining claim should be deprived of his property that has cost him years of hard labor and thousands of dollars in hard-earned money? If it is, the prospector had best lay down his tools and quit, and capital had better seek other, safer, and less venturesome investments than mining in Nevada.

M. H. JOSEPH.

Republic, Washington, January 28.

[Our correspondent's letter opens a large subject of great importance to miners. We will be glad to have discussion, reserving for the present our own comment.—EDITOR.]

Nominations for the Institute

The Editor:

Sir—The following statement of the Committee on Nominations of the American Institute of Mining Engineers has been placed in my hands, with the request that I give it prompt circulation. I do so at once, believing this act to be simply one of justice to the Committee, who gave, to the best of their judgment, laborious service to the Institute. The members may not support their recommendations, but all who know of their efforts must realize that rarely in the history of the Institute has service been so freely given without regard to time or personal expense.

JAMES F. KEMP.

New York, February 10.

Dear Sir—A recent circular to the members of the American Institute of Mining Engineers by Karl Eilers and Charles Kirchhoff, presenting the name of Joseph Struthers for Secretary of the Institute, demands comment from the Nominating Committee, whose decisions are severely criticized.

Considered of itself, it is the privilege of any member to present candidates in opposition to a ticket named by an officially appointed Nominating Committee. In fact it is an evidence of interest in the affairs of the Institute, which is most welcome. When, however, the nominators go out of their way to attack the methods of the committee, and by implication at least, to suggest that they were dishonorable, it is proper to explain to the members the attitude of the Committee.

A better understanding of its decision may perhaps be given by clearly stating just what are the duties of the Nominating Committee. It acted upon the theory that its duties were something more than

clerical. It considered itself to be a body, widely acquainted, without axes to grind, appointed by the President of the Institute to recommend candidates who, if elected, shall fitly represent the best ideals of the profession. It sought, however, the widest possible consultation, personal and by letter, with the members, requesting expressions of interest. The many letters received in response were of great assistance. By its request, however, the Committee did not bind itself to accept advice from those whose information was more limited than its own. In making final decision, the Nominating Committee would have been recreant to duty had it failed to give careful thought to recent events in the affairs of the Institute, and to all the facts and arguments brought to its attention through personal discussions and letters regarding the qualifications of gentlemen suggested for nomination. The Institute of Mining Engineers is a body so widely scattered that not ten per cent of its members are so located that they are familiar with its details, even should they so desire. The Committee, therefore, considers itself as a Trustee for its members, bound in all good faith to judge the candidates for office in the light of their past history and by the strictest standards. Acting thus, its refusal of a renomination of Mr. Struthers was because of its belief that such a nomination would mean a vote of approval by it of the past practices of having salaried officers of the Institute conduct its excursions on a speculative basis of profit from the members. A further reason was that many members had been indifferent and dissatisfied for years, feeling scant consideration had been shown them, and that the welfare of the Institute seems to demand a change in order to renew interest and harmony.

The Committee has made no threat that "if Mr. Struthers should be named by the Committee or anybody else, certain alleged vouchers and documents, damaging to the reputation of the late management of the Institute, would be published in one or more technical journals to which they have already been communicated." The Committee had and has no intention to publish any vouchers or documents. It is hardly their province to do more now than to attempt to make their viewpoint clear to members.

The Committee has been criticized because of failure to renominate all the councillors and vice-presidents of the Council whose terms had not expired. Its nominations were made with full consideration of the revised articles of incorporation, and the proposed new constitution, giving geographical distribution to the Directors, in the hope to avoid the former charge of undue local control, trusting that the scattered membership may feel that their wishes are consulted, and that through their representatives they may gain closer acquaintance and greater interest in the affairs of the Institute. Within the membership there are many men who would worthily and efficiently fill any office in the gift of the Institute. Among these surely all those named by your Committee should be included. They are worthy the support of the membership at large.

NOMINATING COMMITTEE.
PHILIP N. MOORE, Chairman.

Secondary Sulphide Enrichment of Ores

The Editor:

Sir—As a contrast to the scholarly contribution of C. F. Tolman, Jr., to the literature of this subject, the following paragraphs, taken from a report signed by 'Wm. C. Haverstick, M.E.,' will perhaps interest and amuse your readers.

COPPER

"A red ductile, tenaceous, maleable metal of great and varied use, originally called brass of cypress, copper sand, alacaunte, C group of minerals, mostly soft, included C cuprite, malaconite, malachite, malconite, chessylite, chrycopyrite, olivnite, etc. Black C ore, malaconite, gray C ore, Chalcocite, C Purite, yellow C ore, variety Chalcopyrite, the common ore.

"The formation of the Harris Copper Company have blended with the iron lime and porphyry with quartz. Many of the above minerals, but more especially the commoner forms with oxides condensed formation on the top with the iron and lime, with a great amount of carbon and sulphur in the schist formation, with an amalgamated condition of the various mineralizations where gold and silver predominates. The schist formation being soft it stands to reason that when the sulphides appear in the lower rocks, I am led to believe from the geological lay of the uplift that is now held and owned by the Harris Copper Company there is beneath the surface of this great iron capped ledge a great body of copper ore. The sulphides appear so close to the surface that in every instance where digging and mining will be done on these great ledges, ore will be found before any great depth is reached in shaft or tunnel. The Copper Reef shaft of this Company's holdings is located on the same ledge as the Kay Copper Company's mine and will produce ore of as great value when sunk to same depth. This district of the Bradshaw Mountains has the ear-marks and the ledges, and they are not hidden by an overlap of porphyry and boulders, and faulted in any way to make mining expensive. There is a gold and silver bearing formation on the surface, copper glance is visible, and the lime shows the copper stain in the formation of the Last $ No. 2. Sulphur appears on the surface of the walls of the tunnel in great bodies and at the surface the rocks show copper. This ledge has the appearance of being the center of the massive body of this iron and lime dyke in the center of the uplift, as the rocks are regular and not faulted.

"The natural conditions of the ledge shows a perfect leaching of the copper on the surface, and the oxidization zone is well developed and distributed by nature. There exists a perfect distribution of the metal through the length and breadth of the entire contact of this monster ledge."

In the light of this contribution it may be suggested that possibly the reason why some copper mines have not proved profitable is that their oxidation zones were not sufficiently well distributed by nature throughout the geological lay of the uplift as to produce the necessary blending and amalgamation of the mineralizations.

MINER.

Oakland, January 29.

Special Correspondence

MEXICO

NEW INVESTMENTS IN MEXICO.—DEVELOPMENT IN HIDALGO.—LIGHTING PROFITS.

English concerns already heavily interested in Mexico apparently are willing to increase their investments, notwithstanding the disturbed condition of the country. For some time Esperanza, Ltd., has been seeking another big property in Mexico, and the Camp Bird option on the Noria mine in the Sombrerete district of Zacatecas was recently announced. Now the Exploration Company of England & Mexico, a subsidiary of the Exploration Co., Ltd., has taken an option on the old Espiritu Santo mines in the Taxco district of Guerrero, and the A. Goerz interests have taken over the Veta Grande, one of the famous old producers of the Zacatecas district of Zacatecas. The price named in the Espiritu Santo option is said to be over ₱1,000,000, and engineers of the Exploration Co. are now making an examination. This company was the purchaser of the Bueno Tierra mine in the Santa Eulalia district of Chihuahua, and of a controlling interest in the Santa Rosa property in the Concepcion del Oro district of Zacatecas. The Goerz interests are doing extensive work at the La Fe y Anexas properties in the Zacatecas district, and are building a 30-stamp concentrating and cyaniding plant. The initial payment on the Veta Grande was ₱10,000, and plans for extensive work there are being made. There is a big dump on the Veta Grande property.

The 1912 production of the Greene-Cananea was 48,346,300 lb. of copper, 460,816 oz. of silver, and 7425 oz. of gold. The Miami concentrate and other custom material handled made the total copper output for the year approximately 80,000,000 lb. It is expected that the 1913 production of Greene-Cananea will be considerably in excess of that of 1912. A preliminary report issued by the Mines Company of America, operating the Dolores and El Rayo mines in Chihuahua and the Creston Colorado and La Dura properties in Sonora, shows a net profit of $600,000 for 1912. The gross production was approximately $2,400,000, and the expenses $1,800,000. The company's report shows a claim against the Mexican Government of $36,000 for damages suffered at the hands of rebels. The Mines Company has returned to its former dividend basis, and now is disbursing, from the earnings of the last quarter of 1912, a total of $104,500.

Engineers report that the extensive exploration and development work of the Robert Towne interests at the Flojonales copper properties, in the Zimapan district of Hidalgo, has resulted in proving over a million tons of copper ore. Work was stopped recently, and attention now will be given to the metallurgical questions, preliminary to erection of reduction equipment. The Flojonales properties and those of the San Antonio Copper Co., a Cole-Ryan concern, in Sonora, are expected to figure prominently in Mexico's copper production during the next few years. In the Zimapan district the Hidalgo Copper Mining & Smelting Co., which has been operating a 25-ton copper furnace, has blown in a lead furnace of the same capacity. In the El Chico district of Hidalgo the Mancera interests are building a 100-ton plant to treat the ores of the Arevalo vein, which was cut recently by the big Nepton drainage and transportation adit at a depth of 350 metres. A 50-ton plant built to treat ores from the mines of Ludlow Bros. and associates will be in commission in March.

The Mineral Development Co., which is running a cross-cut from the Nueva Luz shaft to reach the 'mother lode' of the Guanajuato district at depth, has cut 2½ ft. of sulphide ore assaying 100 gm. ($2) silver and 2 gm. ($1.33) gold per metric ton. The cross-cut is on the 600-metre level (1966 ft.), and while the vein is of no commercial importance, it shows the presence of gold and silver at that depth. It is expected to cut the 'mother lode' within 700 ft. of the point where the vein was cut. The Providencia Mining & Milling Co., a Guanajuato concern that started milling in 1911, reports a gross production in 1912 of ₱627,380, and profits of approximately ₱105,517. The company's mill handled 55,852 tons of ore.

Mining concerns of the El Oro and Pachuca districts contributed materially to the success of the Mexican Light & Power Co. in 1912. This Canadian concern, owning the big Necaxa hydro-electric plant and supplying the districts mentioned as well as the Mexican capital, has gross earnings in the year just closed of ₱8,918,700, an increase of ₱672,441, and net earnings of ₱6,478,088, an increase of ₱884,905.

ZACATECAS.

BUTTE, MONTANA

HEARTLESS CORPORATIONS.—MODOC SHAFT.—CLARK CONCENTRATOR.

Under the new three-year contract between the unions and the mine operators of Butte, the miners should have received $3.75 instead of $4 per day in January. In other words, the price of copper for the month averaged lower than 17c. per pound. The contract calls for $4 per day when copper is over 17c., $3.75 when copper is between 15 and 17c., and $3.50 per day when copper is lower than 15c. The mining companies of Butte paid $4 per day in January regardless of the agreement. In other words, they gave the miners and other employees about $75,000. But it will not take the agitators long to trump up a motive for this generosity.

The feat of raising and sinking a shaft at the same time is a common occurrence at Butte. Sinking the Modoc shaft of the Anaconda Copper Mining Co. from the 1600-ft. level and raising at the same time from the 2800-ft. level of the High Ore mine has just been completed. The connections were exactly correct and reflect much credit on the surveyors in charge. The Modoc shaft has been equipped with a powerful hoisting engine and will be used as an auxiliary to the at present overworked High Ore shaft.

The Timber Butte Milling Co., a W. A. Clark enterprise, is rapidly rounding into shape its final plans for the concentrator in course of erection south of the city. An electric railway has been built to the site, a large machine-shop erected and equipped, and receiving ore-bins with a capacity of 1000 tons are in course of construction. The mill is to treat ore from the Elm Orlu zinc mine. It will be completed and in operation some time this summer, according to present plans.

Creditors of La France Copper Co. who recently bought in the assets of the company for $100,000 at sheriff's sale, have organized the Atlantic Mines Co., with a view to reopening the Lexington mine. Details of the new company have not been learned other than that the stock is to be sold at $10 per share.

After much talk and considerable delay, Butte is soon to have a cyanide plant in operation. The concentrator and cyanide plant of the Butte Central Copper Co. is expected to be operating full blast before February 15. The equipment of the mill is new and first-class in every respect, so that if the complex sulphides of Butte can be

cyanided profitably, this plant should do it. Also, if this plant proves a success, a marked revival in the silver zone of Butte will result, as the Ophir mine of the Butte Central has ore deposits typical of many of the silver veins in the western section of the district.

The Bullwhacker leaching plant is supposed to be in operation, but not much has been said about it lately. It is apparent that the details of operation are not successfully worked out as yet.

The Minneapolis, St. Paul & Sault Ste. Marie railroad is to spend $25,000,000 in the construction of a line across northern Montana, connecting with the Canadian Pacific again, north of the Idaho line. This work is to begin forthwith. It will open up new coal territory in eastern Montana and will tap some heretofore inaccessible mineral districts of western Montana.

JOPLIN, MISSOURI

ZINC PRICES SLUMP.—DECREASED PRODUCTION.—ACTIVITY IN AURORA.

Both spelter and zinc ore have rapidly decreased in price during the past few weeks, spelter now being quoted at less than $6.60 per cwt., East St. Louis, while zincblende has fallen to less than $50 per ton, assay basis of 60% zinc. The basis offerings range down to $40 for small and less desirable lots, while the choicest ores bring as high as $53. Only a few months ago zincblende sold for as high as $67 per ton, while the basis was as high as $64. Spelter, which reached $7.50 toward the close of 1912, has been falling steadily. The high price of this metal made it possible to import European spelter at a profit, and heavy importations were a big factor in 'bearing' the local offerings. As a result of low ore prices virtually every sheet-ground mine in the Missouri-Kansas-Oklahoma district has discontinued running double shift, and in some cases the mines have shut down altogether. Some of the larger producers are talking of forming a selling agency, disposing of the entire output of the district through a central office. This plan has been advocated, but as yet the operators have never been able to agree on any definite plan of action.

The United Zinc Companies has begun pumping operations in the Aurora district on a big scale, and as a result 29 new shafts have been started by lessees on the grounds of the companies. A centrifugal pump, with a capacity of 1600 gal. per minute, has been installed and is draining the ground to a greater depth than the level of any previous mining operations. Two other smaller pumping stations are now in operation by other companies in the Aurora district. The American Zinc, Lead & Smelting Co. has also begun extensive deep drilling in that district with the view to blocking out orebodies to permit milling on a large scale. The American company has been drilling at both Miami, Oklahoma, and Sarcoxie, Missouri, but has withdrawn from both.

H. C. Felker, a local abstractor of titles, has sold for fifty times the price he paid for it, a 4-acre tract of land in the heart of the Klondike district, 7 miles northwest of Joplin. Two months ago, while looking for a mining lease near the new Yellow Jacket and Yellow Pup mines, which have proved such prolific producers of high-grade zincblende, he decided on a location in the very heart of the mining region, but on which there was no trace of mining. In trying to find the owners of this land he discovered, to his amazement, that these four acres had never been taken up. He immediately placed a claim on this small strip of 'no man's land' and procured a title, the total cost being $10. He sold it to a mining company for $500 a few days ago.

One of the longest underground channels yet found in the district has been discovered at the Heather mine, Thoms Station. At a depth of 130 ft. the operators came into the cavern, which extends from the southeast to the northwest. It has been explored for a distance of almost a quarter of a mile with no trace of its end being found. Further exploration will be conducted when the water can be lowered sufficiently. The channel is unusually large and the sides carry ore, zincblende and galena being found.

With more mining development under way in all parts of the district than at any previous time, the gradual removal of the mine waters is of interest. Everywhere the water has been growing less, and in many districts it has been found necessary to extend pipe-lines to the nearest creeks or rivers for water with which to operate the mills. In the West Joplin group of mines, where there was too much water, instead of too little, prior to the recent activity, the drifts of all the mines are now dry and water is pumped from Short creek, several hundred yards distant. Similar conditions exist almost every place where mining has been conducted on a big scale. At Miami, Oklahoma, the water is being drained to a depth of 300 ft., and shallow operators are no longer forced to do any pumping. Formerly all the mines of this district found the water problem difficult of solution.

LONDON

FLOATING TIN MINES.—AUSTRALIAN TIN.

At the present time every promoter in London has some sort of Cornish property in hand, waiting for a favorable opportunity of floating it. But political affairs on the Continent are supposed to be preventing the ready subscription of capital. All sorts of properties have been acquired, including has-beens, 'never-wasers,' and unproved surface prospects. New companies are being registered every day. One has made its bow to the public this week, and as it has secured sufficient underwriting, the scheme will go forward without interruption. The company is called the Treburland Wolfram & Tin Co., and it has been formed to acquire a new property in the north of Cornwall, near Launceston, and situated at the contact of the Bodmin Moor granite batholith and the Devonian slates. On this property four veins are exposed for 1000 ft., varying from 5 to 20 ft. wide, some parts being in the nature of a stockwork. The depth so far attained is not great, 20 ft. being the maximum figure mentioned. The average content of the ore is given at 1% tin oxide and 3% wolframite. At the present time wolframite does not bring so high a price as tin oxide, and it is, moreover, difficult to sell, for tungsten has a limited consumption. Bodmin Moor is a district that has been neglected of late years, but with the high price of tin development ought now to be possible. The Treburland is evidently an outcrop property of great promise.

The tin people in London have been particularly interested in the developments at the new tin lodes discovered at Ardlethan in New South Wales. Not much London money has ever been invested in the tin industry of New South Wales, though it is well represented in the silver-lead-zinc mines at Broken Hill, and in the copper and gold mines in the Cobar and Mount Boppy districts. Hitherto the tin mines have been almost entirely gravel properties, situated in the Inverell, Emmaville, and Maryland districts in the far northeast of the state. Some years ago a lode deposit discovered at Buddigower, in the centre of the state, 300 miles west of Sydney, but it did not last long. The new discovery at Ardlethan is not far away, so that, though the outcrops are fabulously rich, the Government Geologist is chary about prophesying persistence in depth. Possibly the Australian correspondent may have something to say about this property, and I only mention it in its bearing on the spirits of London speculators. Though any participation in Ardlethan by English people is improbable, the richness of the deposit is being quoted as a 'bull' point for everybody interested in the future of tin properties in any part of the world. Comment is also made on the fact that the outcrop in the outskirts of a fairly populous town should go unnoticed for so many years. Boulders up to a ton weight assaying 40% tin have formed a feature of the landscape, but as they are covered with iron oxide and carbonate formed from the pyritic content of the ore, their true nature was not realized. The fact that surface deposits are still awaiting recognition is another point seized by those whose business it is to keep the investing public interested in min-

ing speculation. All sorts of facts of this kind are being collected as a counterblast to H. C. Hoover's recent gloomy prophecies as regards the future possibilities of the discovery of new orebodies on the surface.

SPOKANE, WASHINGTON

WORK AT CHEWELAH.—PRODUCTION FIGURES.

During 1911 the mines of the Chewelah district shipped a little less than 700 tons of ore to the smelters. During 1912 the shipments aggregated nearly 3500 tons. The International Diamond Drill Co. has taken contracts from the United Copper and Aurora companies for several thousand feet of boring. Drills for the work have been delivered on the ground, but operations will not begin before March 1. According to the report of Conrad Wolfle, president and general manager, the gross revenue from the United Copper mine for the year 1912 was $226,000, and he estimates that the output in 1913 will amount to approximately $660,000. A contract for 200 ft. of an adit on the Widow's Mite claims, one of the United Copper group, has been finished, and the showing is so encouraging that the adit will be continued. The United Copper Co. paid $40,000 in dividends in 1912, but suspended dividends after the November payment, in anticipation of a hard winter and increased costs of mining.

At the Standard-Chewelah mine two north-south veins have been opened by shafts, and a vertical shaft about midway between them, formerly sunk to a depth of 200 ft., has been re-timbered. Ore assaying about $75 per ton in copper was found in the east vein at a depth of 75 ft. In the vein west of the vertical shaft a shaft was sunk 40 ft. on a 30-ft. vein, showing ore up to about $50 per ton value in copper and 2 oz. silver per ton. From the vertical shaft a cross-cut has been driven eastward 175 ft. and has about 75 ft. farther to run to strike the east vein. A cross-cut from the same shaft is in 200 ft. toward the west vein and is expected to reach it 35 ft. farther. A 75-hp. boiler and pump have been installed in the vertical shaft, and an air-compressor and hoisting plant will be erected as soon as the cross-cuts are completed. The company expects to begin shipping ore in 60 days. The boiler and other equipment lately purchased by the Gold Cube Mining Co. are now on the ground. An adit has been driven 150 ft. by hand.

The Blue Star Mining Co.'s affairs have been adjusted, and operations will be resumed about March 1. The Allandale Mining Co. has closed a contract for 150 ft. of development work on claims near Blue creek. From the Clugston mine the first carload of ore has been shipped, making 40 tons, and smelter returns show an approximate profit of $21 per ton. At the High Grade mine exceptionally rich copper oxide and silver ore has been developed on the 120-ft. level. The company will sink deeper and drive on it.

The Nellie S. Mining Co. has been reorganized, and is now the Arcade Mining Co. The capitalization has been raised from 500,000 to 1,500,000 in $1 shares. It is planned to sink to the 200-ft. level and explore for shipping ore. A shaft is being sunk and timbered on a small vein on the Juno-Echo mine. At a depth of 200 ft. a cross-cut will be driven to a wider vein, and ore will be stoped. The wider of the two veins has been developed by open cuts and large quantities of ore have been mined. The Chewelah Development Co., organized by local men, has secured a 2-year bond on two tracts of land at the north end of the Chewelah district, with the mineral rights, and have started an adit to develop two veins at respective depths of 200 and 220 ft. The adit is now in over 20 ft. On the Copper Jack claim of the Metahorn group rich ore 3 ft. wide has been cut in a shaft at a depth of 40 ft. The U. S. Copper-Gold Mining Co. is extending an adit from the east side of a group of claims, under contract, expecting to reach the vein about 60 ft. ahead. The Castle Creek Mining & Smelting Co., at Park City, 25 miles east of Republic, is erecting a 100-ton concentrator, expecting to ship concentrate to the Granby smelter.

NEW YORK

EASTERN FINANCIAL SITUATION.—COPPER MARKET.—GUGGENHEIM REPORT.

The situation at Eastern financial centres can probably be best described as one of feverish interest, but altogether without activity. For the past two years or more the public support given to the financial institutions of the East has taken the form of purchases of preferred industrial stocks and public utility issues as distinguished from any kind of speculative trading. The increased cost of living has created an unparalleled demand for securities of higher yield than the so-called gilt-edged railroad bonds and similar issues that return to holders but 4½ to 5% per year. The result has been a distinct change in the manner of the inflow of capital to Wall Street. The trader who sought for market profits in the fluctuations on the floor of the Exchange has been very largely educated into an investor. The recorded volume of business on the Stock Exchange and in the outside market has shrunk to what is very nearly an irreducible minimum. Along other lines the activity was never greater. The public has absorbed many millions of the securities of manufacturing companies, traction companies, hydro-electric light and power companies, and all this to the exclusion in large part of the flotation of anything pertaining to mining. "The old order changeth," and there must necessarily be some striking readjustments before Wall Street as a whole can hope to enjoy a steady, thrifty, and well distributed volume of business.

The copper situation cannot be said to have improved. The figures of the Copper Producers' Association show an increase of 17,885,750 lb. of copper in accumulated stock. January production was a trifle larger than for the month of December. So far as the copper market is concerned, the consumers seem to be as fully in command of the situation as were the producers a few months since. The price concessions which have been made so far seem to have in no degree altered the attitude of the manufacturers, who have been so unbroken in their stand against accumulating any copper. It has been found during the past few days practically impossible to elicit any kind of an opinion or discussion of the situation among copper people. Among those who will talk at all, no two agree. Some copper was offered this week at less than 15½c. per pound, with no takers, and it is stated that some sales were actually made as low as 15c. The red metal seems to have something that makes it most attractive to big, wide-visioned speculators, but it seems also to be, as a vehicle for speculation, exceedingly hard to control. If, as might possibly be argued from the present outlook, those powerful interests who have succeeded in advancing copper from below 13c. to above 17c., and whose activities began with the inception of the so-called policy of curtailment, and whose circle includes so much of the banking strength of the world, are now to find themselves unable to dominate the situation, then it must hereafter be considered foolhardy to attempt any regulation of the copper-metal market.

Some encouraging news regarding discoveries in several of the younger properties has been finding its way to the market-places. Superior & Boston, a neighbor of the Old Dominion at Globe, Arizona, is stated to have recovered the Old Dominion vein after having driven along a fault for several hundred feet. Where the vein has been picked up it has been found to be very rich and the orebody extensive. There has been, especially for Boston account, quite a little quiet accumulation of shares. The Shattuck-Arizona, one of the showy producers among the smaller and newer copper mines, has reported a discovery of a large body of lead ore on the 600-ft. level. Shipments of one carload per day will be made to the El Paso smelter. From present indications this new source of revenue will add somewhere between $30,000 and $40,000 per month to the company's income. Evidently, all of the negotiations which some three months ago were under way for the purchase of the Shattuck have been dropped. Recent developments at the property have been so encouraging that

the differences between buyers and sellers have been increased rather than diminished. The history of the Majestic Copper Co. has been for the most part one of reorganizations and disappointments. Perhaps the present shareholders are now to receive some reward for their patience. On the Old Hickory ground, according to announcement, there has been found in an open cut a 20-ft. face of ore, 8 ft. of which shows a copper content of 25 to 35%. Twenty carloads of ore are said to have been shipped, and what is apparently the same body of ore is thought to have been opened in one of the mine workings on a level 135 ft. below the open cut.

The board of directors of the Butte & Superior has been partly reorganized, with N. Bruce MacKelvie, of Hayden, Stone & Co., as president, succeeding A. B. Wolvin. It is the general understanding that the greater part, if not all, of Mr. Wolvin's holdings in Butte & Superior have been purchased by Hayden, Stone & Co., though Mr. Wolvin retains his place as one of the directors. The board is reduced from nine to five in number, and the new board consists of Mr. MacKelvie, Kurnal R. Babbitt, who is the head of the legal department of the various Guggenheim organizations, D. C. Jackling, Mr. Wolvin, and C. W. Peters, the last named being a part of the organization of the New York office of Hayden, Stone & Company.

The annual report of the Guggenheim Exploration Co. appeared this week, the chief item of interest being the increased holdings in various subsidiary enterprises. As compared with a year ago, the company's holdings in Yukon Gold have been increased by 65,000 shares, while during the same time there have been purchased 97,750 shares of Chino and 121,200 shares of Ray Consolidated copper. Both of the latter are expected to pay their first dividends during the current year. This is foreshadowed by the statement of the president that, while the new purchases have necessarily reduced the earnings available for dividends, it is expected that such earnings will be materially increased in the near future. Ray Consolidated is expected to produce 50,000,000 lb. of copper during 1913 at an average cost of not more than 9c. per pound, while Chino is expected to hold undisputed first place among the low-cost producers; some of the monthly reports showed a copper cost for Chino of 7c., and the management is promising to turn out a year's output at not above this figure. Realization of this prediction will make Chino easily head the list of producers.

The annual report of the Giroux Consolidated Mines Co. has just been given out, and evidently has not been any too well received by the shareholders, as the issue has been one of the 'soft spots' of the market for the past three or four days. During August, September, and December, which were the only months when exclusive underground mining was carried on, there was produced about 3,750,000 lb. of copper at a cost of 10.8c. per pound, exclusive of extraordinary development and construction costs. The financial report shows current assets of $717,000, liabilities of $649,000. Present shipments to the Steptoe smelter total about 1100 lb. per day, the ore averaging from 2.15 to 2.31% copper.

The Cripple Creek merger is gradually taking shape. The Colorado Mines, Railways & Utilities Corporation has been incorporated, with a capital of $25,000,000, under the laws of Delaware. The merger is to include the El Paso, whose stockholders are to be taken into the new company on the basis of 6 shares of the new stock for 5 shares of their present holdings. The Golden Cycle mine and smelter are to be bought for cash by a syndicate, which will underwrite a sufficient amount of new stock to furnish the cash required to make the purchase. The Golden Cycle mill treats a large part of the ores from the various mines of the district, and the company has very few shareholders outside of John T. Milliken and his immediate associates. The president of the new corporation will be Allan L. Burris. The operating staff will be headed by Richard A. Parker, who was at one time associated with the late Cecil Rhodes. The consulting engineer will be J. H. Hammond, and the engineer in charge will be John H. Nichols, who has heretofore been superintendent of the El Paso.

The annual report of the San Toy Mining Co. is interesting in the light that it throws on the conditions prevailing in Mexico. During the year there was mined 7321 tons of ore of a gross value of $314,884, producing net earnings of $106,458, out of which dividends to the amount of $60,000 were paid, leaving $46,458 to be carried forward to surplus account. Covering the unsettled conditions, the report says: "The unsettled political conditions which have prevailed during the past year have made operation difficult and results disappointing. While production has not been greatly curtailed, and while our direct losses have been confined to a ransom of $2500 paid for the release of our superintendent, who was captured by outlaws, the indirect adverse effects have been many. Chief among these is the delay in carrying on diamond-drill exploration. For this reason no progress has been made toward the discovery of orebodies at depth, and all that it is possible to say on that point is that if, on the one hand, nothing has been done to prove the correctness of our theories, on the other hand nothing has occurred to cause any lack of confidence in them.

JOHANNESBURG, TRANSVAAL

DIAMOND MINING.—GOLD MILLING COSTS.—MEYER & CHARLTON PROFITS.

Outside the gold-mining industry, diamonds perhaps attract the most attention just now, as prices are slowly advancing and are expected to be maintained for some time. No new mines of any promise are being opened, and the total production of mine diamonds is not increasing, as is the case with alluvial stones. Copper and tin are not produced to any extent in the Transvaal, only one promising copper mine, the Messina, being at work, which in November shipped 214 tons of concentrate. Of tin, 198 tons of concentrate was shipped, but this shows a marked falling away as compared with a short time ago, and is far from coming up to expectations when full consideration is taken of the huge tin-bearing areas in the northern Transvaal and the high price ruling for tin today. Miscellaneous minerals to the amount of £12,330 were produced in November, but are divided into so many items that detailed notice is unnecessary.

The improved grade of ore sent to the mills on the Rand since the beginning of 1912 was maintained in November, the average for the whole of the Rand being 28s. 2d., as against 28s. per ton in October. Working costs were, however, 2d. per ton higher, so that, as is usual on the Rand, what was gained by sending better ore to the mills was neutralized by the higher cost of working. Another feature of the November returns was the maintenance of increased working profits every month in 1912 so far, showing quite a respectable increase in the working profits, until at the end of November the increased profits reached £1,196,557 as compared with the corresponding period of 1911. The position will be perhaps best explained when it is stated that the increased gold output in 1912 may be somewhat similar to that of last year, but the increased working profit, £1,196,557, for the first eleven months of 1912, compares with an increase of only £157,704 during the corresponding period of 1911. The lowest working cost in November attained on the Rand was 11s. 3d. at the Simmer & Jack Proprietary Mines, the Knights Deep following with a cost of 11s. 8d. per ton, thus confirming the estimate of the consulting engineer of the Consolidated Gold Fields that the acquisition of the Simmer East property by the Knights Deep would add but little to the working cost. About the highest yield obtained on the Rand in November was 42s. per ton, and only three mines were able to show such a yield, the Meyer & Charlton showing the highest profit with 25s. 6d. per ton. The only mine of any importance to show a loss was the Lancaster West, where with a yield averaging 21s. per ton, a loss of £1814 was made. Several mines on the Rand are making good profits with a similar yield, while, with no better yield, the Langlaagte Estate is paying good dividends.

General Mining News

ALASKA

There are now 16 incorporated towns in the territory. Reports from eight of them which have caused an assessment of property to be made, and a tax levied, showed a valuation of $8,432,603. The average tax is 1.14 per cent.

During the year 1912 the Alaska Packers Association's pack was 1,202,779 cases of salmon, 15 canneries being operated and their value being $4,336,262. The Association owns 9 ships, 11 barks, and 62 steamers, the total number of vessels being 86, valued at $1,362,000. Six medical stations are maintained in Alaska, and two salmon hatcheries, from which 107,520,000 red salmon eggs were taken.

Cordova

On January 19 a serious fire occurred at the Bonanza mine, an overheated stove setting fire to the loading station, resulting in the tramway being put out of commission, as the heavy cables fell into the gulch below, carrying away 10 towers. The loss will be about $50,000.

Fairbanks

Lawrence & Albrecht, working on 9 Below, bench claim, Tenderfoot creek, uncovered gravel 5 ft. deeper than a former prospector went some years ago. At the Hudson quartz claims, between Ready Bullion and Moose creeks, drifts are being driven 200 ft. from the bottom of the 100-ft. shaft. The 2-stamp Nissen mill is idle at present. The Chatham mill, of two 2-stamp Joshua Hendy mills, is kept busy on 3 Above, Chatham creek. The Newsboy mill is crushing ore from the Overgaard mine.

At Ruby, there are about 13 parties busy on Long creek, some of which are getting encouraging results. Next spring American creek, in the Hot Springs district, will be busy. There is no continuous deposit there, but good gravel has been worked for three miles, and the coming season is expected to be better than 1912.

Valdez

From the Fidalgo Mining Co., 150 tons of ore, worth $20 per ton, is to be shipped to Tacoma. Ten men are employed at present. From the adit, a surface tramway 900 ft. long is connected with a 100-ton bin, from which an aerial tram 2000 ft. long connects with a 500-ton bin. The wharf is 150 ft. long, and has 26 ft. of water at low tide. At the Alice mine, on Shoup bay, three shifts are sinking the shaft. To date $30,000 has been spent on development. It is intended to drive an adit 200 ft. on the Golden Eagle claim, at Golden, Port Wells. The vein has been opened for 100 feet.

ARIZONA

Cochise County

It is stated that the American Smelting & Refining Co. has taken charge of the properties of the Development Company of America, including the Silverbell, Tombstone, and Christmas, and the smelter at Sasco. F. C. Earle, manager of the El Paso smelter, is arranging to reopen the mines and smelter, which will be operated independently of the El Paso plant. The *Bisbee Daily Review* contains a report by B. O. Pickard on the Gleeson district of this county. The town of Gleeson is reached by two railroads. The Warnekros mines are close to the town. The Copper Belle, leased to the Shannon Copper Co., ships 200 tons of heavy pyrite ore daily to Clifton, Globe, and Tucson smelters. From the Gleeson mine a good deal of ore has been shipped. In the El Tejon, a shaft is being sunk to 500-ft. depth. The Silver Bell mine is a rich lead-silver property, but has been the subject of litigation for many years. An important development has been made in the Uncle Sam workings of the southwest shaft of the Copper Queen mine. Now that its length and width are known, it will be prospected at 200 ft. lower.

In January the Phelps-Dodge mines produced 12,237,331 lb. of copper, of which the Copper Queen produced 6,828,346 lb., Montezuma 2,913,294 lb., Detroit 1,769,071 lb., and custom ores 726,620 pounds.

Gila County

(Special Correspondence.)—The 50-ton test plant for the Minerals Separation flotation process, recently built at the Inspiration mill, was erected and put in operation in 16 hr., which must be a record for construction work.

Globe, February 7.

A promising copper and gold district exists near Payson, in the northwest part of this county. It is connected by stage with Globe, 100 miles; Winslow, 75 miles; and Mesa, 125 miles. Most of the ores are free milling. The Golden Wonder has been opened to the sulphide zone, a depth of 150 ft., and yielded $50 per ton by amalgamation, the tailing containing $10, owing to pyrite. The copper lodes are in porphyry. The altitude of Payson is 5000 ft., climate is good, and there is plenty of water and timber. There are many ancient ruins in the vicinity.

Graham County

The Shannon Copper Co. produced 1,232,000 lb. of copper in January, as against 1,360,000 lb. in December.

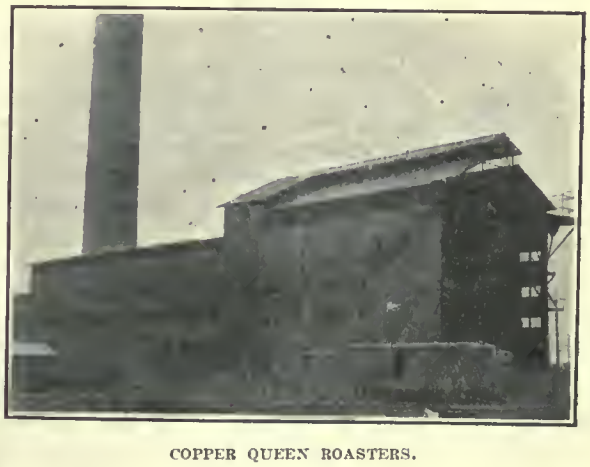
Mohave County

Eighteen miles of copper wire, leading from the power-station at Needles to the Tom Reed mines, has been stolen, and 8 tons was shipped to Los Angeles. The poles were also taken by the thieves. The wire was worth $1000 per mile, and that portion which was not sent to Los Angeles was found coiled on the banks of the Colorado river opposite Needles.

At the Gold Road mine 140 men have been laid off. The mine has a lot of ore broken in stopes, and the mill is being overhauled. The Tennessee mine is shipping 200 tons of ore per day to Needles, and the Golconda, two cars to Oklahoma. From the Smith-Hoffman mine, a Saurer truck recently brought in 6 tons of rich silver-lead ore.

Yavapai County

At the Climax mine the new air-compressor and three machine drills are at work, while the mill is being overhauled. The Big Seven group, near Harrington, has opened 36% copper ore. A mill will be erected at the Hooper mine on Ash creek. Good progress is being made at the Black Chief mine, in the Black Hills, in unwatering and cleaning out old workings. Good ore has been opened in the old Gladstone claim. The dredge of the Speck Mining Co. is being moved 1½ miles down Lynx creek. Preliminary work is being done at the placer claims of J. Philips, about 10 miles south of Prescott. From the Silver Tip mine, on Turkey creek, 7½ tons of ore, averaging 54 to 110 oz. of silver, has been sent to El Paso. The Monte Cristo shaft is down 650 ft., and rich silver ore has been opened.



COPPER QUEEN ROASTERS.

The Humboldt Consolidated Mines Co. will sink its North Star shaft to 250-ft. depth. At the Haynes mine 30 men are doing development, including shaft-sinking. Ore 2 ft. wide has been cut on the 800-ft. level of the Pick and Drill mine. A cave-in at the Laura claim exposed a vein of good ore. The Anderson patent amalgamator at Mayer has been moved to Lynx creek, where there is plenty of

water. Ten per cent copper ore 11 ft. wide has been opened in a drift from the winze in the Commercial Mining Co. mine at Copper Basin.

CALIFORNIA

Amador County

(Special Correspondence.)—The 20-stamp mill at the Hardenburg mine is about finished, and it is expected that milling will commence before the end of February. The plant has a daily capacity of 100 tons. An option has been taken on the Crown Point and Yellow Jacket claims, in the Drytown district, by H. DeC. Richards, of San Francisco. The property has been idle for 20 years. It is rumored that good ore has been intersected in the upper portion of the Plymouth Consolidated mines. Considerable prospecting is being done at the 1600-ft. and upper levels. It is stated that George W. Brown is reported to have sold his South Jackson property for $25,000 to Eastern people. The shaft at the Memphis is down 200 ft. and is being sunk 100 ft. farther. From this point a cross-cut will be extended to intersect the vein. The mine is near Drytown, a short distance north of the Fremont-Gover group. It is being operated by Monteverde & Scharoni Bros. Small shipments of rich ore continue to be made from the Mountain Queen mine, near Pine Grove, 9 miles from Jackson. Fair progress is being made cleaning out débris from the caved portion of the South Eureka shaft, and about 125 ft. has been placed in working condition. It is still impossible to accurately estimate the extent of the damage, although sufficient work has been done to allow escape of the gas from the lower workings. Meanwhile, operations continue suspended at both the South Eureka and Central Eureka mines.

Jackson, February 2.

Nevada County

Some rich ore has been opened in the Osceola vein, in the Rough and Ready district, by E. W. Tarr. The claims in this locality have not been worked to any extent during latter years.

Shasta County

The Stowell group of copper claims, between the Balaklala and Iron Mountain mines, has been bonded to the United States S. R. & M. Co., the parent company of the Mammoth Copper Co. of Kennett. The bond is for $75,000, for one year. Development has begun by the Mammoth company. These claims were once bonded for $200,000, but the price was too high. They are near the Mammoth smelter.

Sierra County

Water in the Sierra Buttes flume has reached the mine, and work underground can be resumed after a shut-down caused by the water freezing. A small snowslide started at the side of the dump-shed of the Monte Cristo gravel mine last week, but no damage was done; while at the Telegraph and White Bear mines timber and air pipes were scattered about by another slide. At the Keystone work has been resumed, the danger of snowslides having passed. Owing to the heavy fall of snow this winter, there will be plenty of water for all mining purposes in the coming spring and summer. The Alleghany Mining Co., which owns the Balsam Flat mines on Lafayette ridge, will extend its adits to cut the gravel to the east of the old workings. B. Gordon is superintendent. The Mt. Alta mine at Pleasant View has uncovered a large gravel deposit which will be worked as soon as possible. At the New York tunnel a snowslide over 300 ft. wide demolished all the buildings. A good deal of the timber will be recovered. Probably an electric-power plant will be erected near Sierra City to supply power for the Sacred Mound property. It is stated at Forest that the Covotoman and Young America gravel mines will be reopened.

COLORADO

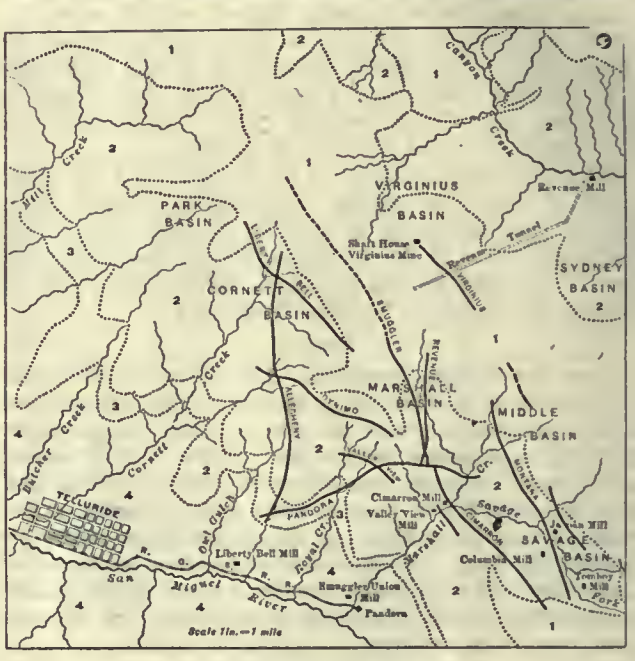
Clear Creek County

(Special Correspondence.)—Work will start this week in preparing the Capital adit for the installation of the electric trolley system. Under the terms of agreement the Onondaga Mining Co. pays all costs of the improvements in lieu of being granted a perpetual right of way. Construction work on the new mill building for the Dives-Pelican and Seven-Thirty mines will be instituted soon. G. W. Tarkington, general manager, has returned from a southern trip, and funds have been secured for large development. The operating company will build an aerial tramway from the dumps of the Colorado Central mine, the terminus to be at the new mill. Shipments have been started from the Tobin mine in East Argentine. The first-class ore mills from $275 to $300 per ton in gold, silver, and lead. Johnson & Co. are operating under lease. Hanson & Co. have secured a lease on a block of ground on the Paymaster vein that was intersected by the Wilcox adit 4000 ft. from the portal. The streak is 10 in. wide, and will mill close to $80 per ton in silver and lead. It is stated that work will be resumed during the present month on the Marshall-Russell adit on Miller mountain. The adit that has been driven 7000 ft. will be extended 5000 ft. farther.

Georgetown, February 3.

Gilpin County

The claims of the Calhoun Consolidated Mines Co., on the east slope of Quartz hill, have been leased for three years by the Mountain States Investment Co., which will do extensive development, the mines already being opened



MAP OF SAN JUAN DISTRICT.

from 290 to 980-ft. depth, and a length on the Calhoun vein of 3500 ft. These claims were located in 1859. The Bullion Mining & Milling Co. is opening rich silver ore in its adits. In the Evergreen mine, at Apex, three ore-shoots have been cut on the 350-ft. level, carrying 8 to 20% copper ore.

Gunnison County

The Maid of Athens and Citizens mines, seven miles from Pitkin, shipped 23 cars of ore in January, making 45 cars since last October. Both mines are worked by one adit, and 20 men are employed, by the lessee, F. Ballou, of Denver. J. F. Robinson is superintendent. Total production is about $500,000.

Lake County (Leadville)

Owing to the drop in prices of zinc, all ores below 25% will not be accepted by smelters, and consequently a number of mines are not being fully worked. The flow of water in the Yak tunnel winze became so heavy that another pump had to be installed.

Ouray County

During January the Mountain Top adit was extended 360 ft. in hard rock, equal to about 12 ft. per day. In the Humboldt, the north drift has opened high-grade ore

for 150 ft. in length. At the old Ouray foundry, an effort was made to smelt a quantity of copper ore in the blast-furnace, and pyrite smelting was tried with a fair degree of success. It is proposed to sell the Red Mountain property again, the owner, J. F. Thompson of California, having bought it in September last. During January 65 cars of ore and concentrate were shipped from Ouray. Total costs on the Monntain Top adit in January were $14.76 per foot driven.

The Smuggler-Union 60-stamp mill is in full operation after a shut-down of 30 stamps for a few days. The traction cable of the Tomboy new tramway is about finished. The Rico-Argentine company has constructed a short tramway, which will reduce haulage costs. The Suffolk mill at Ophir is handling 150 tons of ore per day. The Kuehn patent amalgamator is to be tried in the district shortly.

San Juan County

Following are the shipmenta of concentrate and crude ore from the Silverton district during January. Concentrate: Sunnyside 675 tons, Iowa Tiger 250, Silver Lake 300, Vinyard & Co. 125, and Gold King 550 tons; total 1900 tons. Crude ore: Gold Tunnel 225 tons, Dives 75, and Ed. Fiant 50 tons; total, 350 tons.

San Miguel County

The Ophir Gold Mines, Milling & Power Co., at Ophir, is operating the Suffolk group of mines, which produced $2,000,000 in three years. The ore averages $5 per ton in gold, and will be treated in a 20-stamp mill, with 850-lb. stamps, the boxes having ¼-in. screens. Ore will be crushed in cyanide solutions, and classified in a Dorr classifier, the coarse material being reground in an 8-ft. Hardinge mill. The slime is thickened in a Dorr thickener, and agitated in a new Dorr machine. Pulp is then to be treated by continuous decantation. Solutions are kept up to 85° Fahrenheit.

Teller County (Cripple Creek)

According to local statistics, the January output was as follows:

	Tons.	Value.	Total.
Smelters	3,872	$65.00	$ 251,680
Golden Cycle	28,500	20.00	570,000
Portland	9.876	21.00	207,396
Portland (C. C. district)	15,100	3.14	47,414
Stratton's Independence	11,100	2.76	30,636
Colburn-Ajax	4,650	3.20	14,880
Wild Horse	1,100	3.80	4,680
Gaylord-Dante	1,200	3.00	3,600
Kavanagh-Jo Dandy	1,500	2.10	3,150
Isabella	740	1.50	1,110
Total	77,638	$15.40	$1,134,540

The Isabella mine produced 85 cars of ore, shipped mostly by the 20 sets of lessees. During the past year 11,000 ft. of development was done, and the tonnage was between 1600 and 1800 tons per month. At 1275-ft. depth, a shoot is being mined near the shaft. Four Chilean mills are being installed and four Dorr classifiers at the Blue Flag mill. The biggest suit known in the district involving apex rights has been started by the El Paso Consolidated Gold Mining Co. against the C. K. & N. Mining Co. It involves $1,000,000 damages and complete ejectment from operation. Last week the El Paso attorneys served notice on ore buyers that ore from the C. K. & N. mine was the property of the former. The annual meeting of the Portland Gold Mining Co. was held at Cheyenne, Wyoming, on February 3. The old directors were re-elected, the consulting engineers being M. Boehmer, Hills & Willis, and C. W. Merrill. The report of the president, F. G. Peck, dealt with the treatment of the ore, especially in the low-grade mill. At the Colorado Springs mill, two Merrill filters, each of 200-ton daily capacity, were installed. The Victor mill is doing well. The concentrating department was enlarged, and more agitators added. The year's production in this mill was 173,361 tons, yielding $547,424, of which $203,413 was profit. The average value was $3.15, and profit $1.17 per ton. The plant is now treating 500 tons per day. The mine is in first-class condition, and No. 16 level is opening satisfactorily. The Roosevelt drainage tunnel should lower the water 600 ft. below the present workings. During 1912 the total output was worth $1,534,840. Operating costs were $1,091,020, and net profit $322,745. Dividends paid were $240,000, or 8% on the capital of $3,000,000. On January 1, 1913, the balance was $1,782,019. There is some talk in Cripple Creek of erecting a mill to treat 1000 tons of low-grade ore per day, of which apparently plenty can be procured worth $3 per ton and over.

IDAHO

Shoshone County

Records at Wallace show that 9 ft. of snow fell in the Coeur d'Alene mining region in January. The Kearns tunneling machine is to be tried in one of the mines. The Snowstorm mill at Mullan is treating 150 tons of ore per day, this averaging between 2 and 3% copper. The capacity will soon be up to 200 tons. The Federal Mining Co. will probably extend the Standard-Mammoth lower adit through the Cleveland-Greenhill ground recently acquired, into the Tamarack & Custer Consolidated, and eventually into the Hercules, cutting the latter lodes at 500 ft. from the surface.

A 50-ton concentrating plant and a 150-ton capacity aerial tramway will be built for the Idora Hill Mining Co. The latter will be 2000 ft. long, with a drop of 1100 ft., and will discharge automatically into a 500-ton storage-bin. From here the ore will pass over a grizzly and crusher into a 200-ton mill-bin. The silver-zinc ore will be crushed by rolls and concentrated by jigs, revolving screens, and some tables. Power will be supplied by the Washington Water Power Co. The mine has been opened to a depth of 600 ft. and can be developed 1100 ft. deeper by an adit. The mill product will average 50% lead, 25 oz. of silver, and 45% zinc, the crude ore being worth 10% lead, 4 oz. of silver, and 3 to 5% zinc. Glen A. Collins is general manager at Wallace.

MONTANA

Cascade County

At the 500-ft. level of the Florence mine at Neihart, driving south of the fault is in progress, the value of the ore is improving, and stoping will be soon started, after which work will be done on the 300-ft. level, south of the fault. Since January 18, seven cars of ore have been shipped, the last two cars giving a net return of $600 per car.

Deer Lodge County

At the Southern Cross mine all machinery is on the property and the main shaft will be sunk a further 200 ft. The Oro Fino group promises to be a good producer. Ore shipments from the Hold Fast lease will be made this winter to the smelter. The Butte & Anaconda, Red Lion, and Big Bill groups, on the western slope of the Cable mountains, are being actively worked. Good ore has been opened in the Hidden Lake mine, on the eastern slope.

Granite County

The Sunday mine has been acquired by the Royal Mountain Mining Co., and will be developed under the direction of J. L. Meixell, of Butte.

Lincoln County

(Special Correspondence.)—S. G. Ratekin and John Flaveli left on January 31 for the St. Paul mine, near the Snowshoe property, where they will continue work on the adit which is being driven on the lode. This adit is now in about 450 ft., work having been kept up almost continuously for a long time. The vein shows good metal content on the Snowshoe side of the mountain, but the adit is being run from the Cherry creek side, as it is possible in this way to get about 1500 ft. lower down on the vein. The ore-shoot has not yet been cut from this side; but that one exists not far ahead is almost certain, as it shows in the outcrop above. The owners expect that the ore-shoot will be reached 50 to 100 ft. farther on. The St. Paul is owned by F. M. Plummer, S. G. Ratewin, and M. A. Shanahan, all of Libby, and has long been considered one

of the most promising silver-lead properties in the Libby district.

Libby, February 4.

SILVERBOW COUNTY

(Special Correspondence.)—The North Moccasin mine of the Barnes-King company is opening well, and during the first five weeks of the run the net value of ore treated was $32,000, of which $18,500 goes to the company, and $13,500 to the owners of the North Moccasin. Good results are also reported from the Piegan-Gloster mine.

Butte, February 8.

The production of the mines at Butte segregated according to properties, was as follows during January:

	Tons.	Copper per ton, lb.	Total, lb.
Boston & Montana group	102,120	65	6,637,800
Anaconda group	160,000	61	9,760,000
Butte & Boston	13,720	62	850,640
Washoe	7,100	61	433,100
Parrot	2,900	60	174,000
Trenton	12,200	61	744,200
North Butte	30,120	70	2,108,400
Butte Coalition group	34,000	70	2,380,000
East Butte	10,820	110	1,190,200
Tuolumne	4,600	120	552,000
Original	10,200	60	612,000
Alex Scott	7,500	110	825,000
Davis-Daly	2,400	110	264,000
Total	397,680		26,531,340

The Washoe and Great Falls smelters produced 20,948,000 lb., a decrease of 2,500,000 lb. compared with January of 1912.

NEVADA

LINCOLN COUNTY

The Mendha Nevada Mining Co. is to resume ore production. A large Hancock jigging plant will be installed, and about 400 tons per day will be treated for shipment. Water has given a lot of trouble at the Nevada Des Moines.

LYON COUNTY

The Mason Valley smelter received the following ore during the week ended January 28:

	Tons.
From Mason Valley mines	1,844
From Nevada-Douglas	3,287
From outside mines	975
Total	6,106

Fourteen carloads of matte were shipped from the smelter. Development on the 750-ft. level of the Mason Valley mine continues, and the sprinkling system installed is keeping the dust down. From the Malachite mine regular shipments are made to the Thompson smelter; while the Bluebird & Aurora, Yerington Bullion, Shay, Nevada-Denver, Bialne, Guthrie Fraction, Boulter, Copper Belt, Blue Jay, and New Yerington are busy on development and shipping ore.

NYE COUNTY

During 1912, the Tonopah Midway Mining Co. produced 694 tons of ore worth $20,925. The total revenue, including sale of stock was $70,475, and expenditures $63,951, leaving a balance of $6524. Development covered 2627 ft., making a total of 38,063 ft. The new shaft is down 330 ft., and it is hoped to cut the Merger vein by cross-cutting.

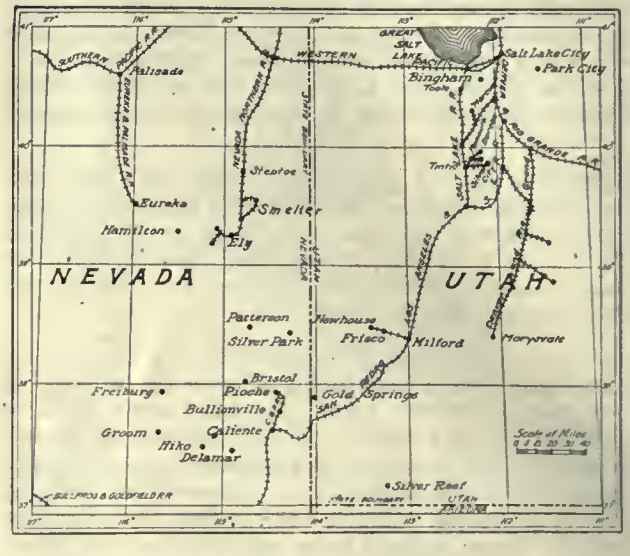
During the week ended February 8, Tonopah mines produced 11,071 tons of ore worth $231,590, making a total for the current year of 63,941 tons and $1,336,420.

S. H. Brady has enjoined the Manhattan Amalgamated Mining Co. from working within the lines of the Manhattan Earl, and is suing for the recovery of the value of 1000 tons of ore worth about $20 per ton, alleged to have been extracted by the company. The total damages are $66,000. The suit is somewhat complicated and has been expected for some time.

At the Mushett-Wittenberg lease on the Big Pine, an electric hoist and head-frame have been erected. Sampling of the Big Four shows 200,000 tons of $10 ore available for treatment.

WHITE PINE COUNTY

The Giroux Consolidated mine is producing 1100 tons of ore per day, from about 200-ft. depth. During January the 700-ft. cross-cut in the Ely Consolidated was advanced to 401 ft. from the Zack shaft, the last 30 ft. being in iron-stained porphyry. During its past year, the company spent $52,460 on development, and had $15,000 on hand at the end of 1912. Work is to be resumed at the Gladys shaft of the Ely Calumet.



PART OF EASTERN NEVADA.

NEW MEXICO

GRANT COUNTY

(Special Correspondence.)—At the Chino mill the double-decking of all Garfield roughing tables, on three sections of the plant, is finished, and the other two sections will be done as soon as possible. It has been stated that the mill capacity will be increased to over 20% by these alterations; but this is not so, although the recovery effected by the roughing system circuit will be increased, due to the relief afforded a machine of this type when the tonnage per deck is reduced by 50%. It has been possible to treat 1500 tons of ore per 24 hr. per section, with the single-deck Garfield tables included in the flow-sheet, but the vanners are fully loaded and further increase in tonnage would be of doubtful benefit.

Hurley, January 30.

The copper production of the Chino mine in January was 3,055,821 pounds.

SAN MIGUEL COUNTY

The Tecelote Copper Co. owns 12,000 acres, on which 25 lodes have been found, but only one has been developed. One shaft has been sunk 600 ft., and about 10,000 ft. of driving and cross-cutting done. One dump on the surface contains 75,000 tons of ore. It is stated that 3,000,000 tons of ore has been opened, which will average 4% copper and $15 per ton in gold and silver. Foundations for a smelter to cost $200,000 have been laid, and by October it should be in operation. There are about 1200 men employed in the Tecelote district, which is 40 miles west of Carbo, on the Southern Pacific de Mexico railroad. W. B. Duvall, of New York, is president, and Ricketts & Banks consulting engineers.

UTAH

JUAB COUNTY

The Yankee Consolidated Mining Co. paid a dividend of 1c. per share on February 1. During the past year, ore shipments totaled 11,406 tons, and total revenue was $86,817. Expenses were $66,918, leaving cash at January 1, $19,909. Development on the 1800, 1900, and 2000-ft. levels covered 3314 ft., and thirty-one 50-ton cars of ore were shipped, av-

eraging 35 to 40% of zinc, yielding net smelter returns of $23 per dry ton. Since January 1, fair ore has been opened on the 1800-ft. level. Twenty-eight Tintic mines produced 43,250 tons of ore in January, worth about $20 per ton. During 1912 the Chief Consolidated Mining Co., covered 5576 ft. in development, and ore shipments totaled 30,028 tons, yielding 7682 oz. of gold; 895,885 oz. of silver; and 817,090 lb. of lead, yielding a net return of $481,474. The mine is in splendid order.

Summit County

It is stated that in the Ontario mine there are 700,000 tons of ore worth about $8 per ton in the old stopes, put there for filling purposes, and the Mines Operating Co. has a 10-year lease above the 900-ft. level, also on the mill, which is now treating up to 100 tons per day by a new process, and will be increased later to 300 tons daily capacity. The Silver King, Daly-Judge, and Daly West mines shipped 2000 tons of ore during the past week, while in January, 11 mines produced 7105 tons.

WASHINGTON

Spokane County

(Special Correspondence.)—Through the operation of the Companies Act, 2000 companies, in many of which are Spokane stockholders, have been denied the right to transact business in British Columbia, and will have to reincorporate at a cost of $5000 to each of the companies affected. Sharp & Irvine, of Spokane, have received an official list of the companies which have been declared under ban from the registrar of the province of British Columbia, at Victoria. Included in the list of companies are some of sound financial standing, owning valuable property, and some of them engaged in the production of ore. The action of the registrar is said to have been the result of the neglect of the companies to comply with that section of the Companies Act which provides that the corporations file with the registrar lists of stockholders, their vocations, places of residence, and other information.

MAP OF WASHINGTON.

Efforts are being made by Idaho legislators to enact a measure governing investment companies doing business in the state, and a bill, similar to the Kansas 'blue sky' law, has been introdnced in the legislature. The act provides for the creation of a state board of control of investment companies, inclnding mining corporations, and carries with it a sufficient appropriation for making it effective, a fund for the purpose to be created by fees paid in by the corporations coming under the jurisdiction of the board. The proposed bill makes it unlawful for any company that sells bonds, contracts, shares, or stocks to nttempt to do business without first filing with the board a complete report of its capitalization, assets, and other pertinent facts, and a severe penalty is provided for non-compliance. Local mining brokers are divided in opinion regarding the effect it will have on their business, as they deal largely in Idaho mining stocks, but many are inclined to believe that such legislation will stimulate rather than decrease interest in mining investments.

Spokane, February 6.

The Washington Water Power Co. made net earnings of $959,493 in 1912. The capital is $14,081,000, and assets are $21,461,374. The number of stockholders is 1231, and prospects are good.

CANADA

British Columbia

It is reported that the 2000-ton smelter at the Hidden Creek mines of the Granby company will be ready by July 1. Five steamship companies will run vessels between Granby bay and Pacific coast ports. During January the smelter at Grand Forks treated 102,149 tons of ore, the copper output being 1,828,245 lb. During 1912 the British Columbia Copper Co., Ltd., smelted 687,256 tons of ore, yielding 11,267,681 lb. of copper, 25,643 oz. of gold, and 141,222 oz. of silver.

Ontario

An English company, the Aladdin Cobalt Mining Co., has bought the Silver Cliff and Chambers-Ferland mines, which are well known in the district. During the week ended February 1, 198 bars of bullion weighing 216,370 oz., worth $134,684 were shipped to England by the Nipissing and Buffalo mines. In January the Cobalt mines sent out 2020 tons of ore and 463,805 oz. of bullion.

MEXICO

Chihuahua

Owing to the inability of the railroads to carry coal to Chihuahua, the 1000-ton smelter has been shut down. If it remains closed it is probable that 3000 men in the district mines will be laid off. The fuel situation is serious; any coal which reaches the city is confiscated by the railroad company to operate its trains. A rush set in for an old Spanish mine near Cusihuiriachic, which was held by an American named Carr, but who failed to pay his taxes. On January 27 there were 178 applications for the claim.

Guanajuato

El Gigante Quicksilver Mining Co., which owns a mine in La Luz district, is producing 20 tons of rich cinnabar per day. H. H. Miller & Co. is erecting a 5-stamp mill. The Mexican Mines, Ltd., controlled by Oregon people, owns La Bonita and Neuva Idria mines, near Mineral del Cubo. The main adit, 8 by 8 ft., will be extended, and an incline shaft sunk. In the former it is expected to cut the famous Nayal vein.

Sonora

After a two months' campaign, the Democrata company's smelter has been shut down, owing to molten matte splashing and setting fire to the wooden parts of the building, causing a loss of about $11,000. The ore-bins were also destroyed. The furnaces will be in operation again in March. The Babiconova mine, in the Chispas district, has been sold to a Pennsylvania company. The new mill of the Moctezuma-Arizpe company is at work and the daily output of concentrate is 12 tons, which is sent to El Paso. This mine is 18 miles from Cananea. The new smelter of the Cobriza Mining Co., 17 miles west of Noria, is being blown in. It is of the Macdonald hot-blast type, of 150-ton capacity.

The Mines Company of America made a profit of $585,000 in 1912, against $834,000 in the previous year. Dolores and La Dura mines were shut down for two months on account of the revolution, the former being looted to the extent of $50,000, partly covered by insurance, and a claim has been made against the Mexican Government. All the properties are working at full capacity now, the Creston-Colorado treating 10,500 tons; Dolores, 5000; El Rayo, 5000; and La Dura, 500 tons per month. Cash, bullion, and supplies total $1,130,000. On the 600-ft. level, the Creston-Colorado has opened 15 ft. of ore averaging from $6 to $10 per ton.

NICARAGUA

(Special Correspondence.)—The Streter interest in El Golfo mine has been bought by L. de Tourniel, who is now the sole owner. Work was continued during the war, and the new mill is now in operation.

Jicaro, February 1.

Market Reports

LOCAL METAL PRICES

San Francisco, February 13.

Antimony	12—12½c	Quicksilver (flask)	40
Electrolytic Copper	18—18¼c	Tin	53½—54c
Pig Lead	4 60—5.55c	Spelter	8¼—8¾c

Zinc dust, 1400 lb. casks, per 100 lb., small lots $9.50—9.75; large $7.50—8.50

METAL PRICES

(By wire from New York.)

NEW YORK, February 13.—Copper prices unchanged; slightly better in tone. Lead is quiet. Spelter remains weak. Average daily prices for the past week, in cents per pound, based on wholesale transactions, standard brands, are given below.

Date.	Electrolytic Copper.	Lead.	Spelter. St. Louis	Silver, per oz.
Feb. 6	15.50	4.33	6.19	62⅛

MANGANESE producers in the Sharopan district in the Kutais government of Russia have requested permission to call a congress of manganese producers to discuss statistics of mine production; quantities of ore in railroad stations and exported; means of transportation to the warehouses of the Transcaucasian railway at Tchiaturi and elsewhere; construction of elevators at Batum for loading ore; construction of branch railway lines in mining regions; bringing water to mines; measures for preserving health of mine employees; organization of insurance of workmen and hospital funds according to the recent law, and other questions.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

C. F. DUVAL is at the Palace.

J. V. N. DORR is at Panama.

J. N. NEVIUS is in New York.

H. F. DAVIS is at Keeler, California.

J. E. JOHNSTON is here from Los Angeles.

E. B. KIMBALL has returned from Mexico.

SUMNER S. SMITH has returned to Juneau.

GUY A. R. LEWINGTON is in San Francisco.

EDMUND JUESSEN is at Carson City this week.

WALTER STADLER was in the city during the week.

O. B. HARDY, of French Gulch, is in San Francisco.

THOMAS KIDDIE is now at West Alhambra, California.

STANLY EASTON has been in San Francisco this week.

W. H. BASSET has gone to Oakland, California, from Tonopah, Nevada.

F. H. MORLEY is at Rome and expects to go to London early in April.

L. DE TOURNILL is now sole owner of the El Golfo mine, Jicaro, Nicaragua.

HOWARD R. STEWART is now at 5 Rodway Road, Roehampton, London, S. W.

WALTER C. ADAMS has left Montreal, Canada, and is now at Durango, Mexico.

JUAN BLANQUIER, who has been visiting the works at Ely, is in San Francisco.

WALTER G. SCHMIDT was in San Francisco and has returned to Los Angeles.

E. M. ROBINSON is manager for the Crown mine, Ainsworth, British Columbia.

S. H. BALL is in Europe, but expects to return to New York by the end of the month.

H. HARRIS is now general manager for the Tasmanian Smelting Co., at Zeehan, Tasmania.

R. G. HALL, former manager for the United Zinc & Chemical Co., was in San Francisco and has gone to Los Angeles.

W. L. POLSON is returning to Alaska to continue development work in South Prince of Wales island, in the Ketchikan district.

W. W. BREEN has accepted the position of mill manager at the Bishop Creek Milling Co., Sonora, Cal.; ALGERNON DEL MAR is superintendent.

A. SYDNEY ADDITON has completely recovered his health, after two years enforced retirement, and is again engaged in consulting work in San Francisco.

L. V. BENDER is now assistant superintendent of the Anaconda smelter; HARRY WARES is superintendent of blast-furnaces; and ROY E. HOWE is chief chemist.

C. T. NICOLSON sailed from New York February 11 for Portuguese East Africa to take charge of construction work on the 7½-ft. dredge the Bucyrus Co. is building for the Andrada Mines, Limited.

FREDERICK LAIST has been made general superintendent of the Anaconda smelter of the Anaconda C. M. Co., succeeding William Wraith, who is now general manager of the International Smelting & Refining Company.

W. A. IRWIN, a mining engineer who has just returned from Alaska, is authority for a statement that Juneau and its vicinity is about to enjoy a substantial mining boom. Several immense low-grade enterprises are being launched, and Mr. Irwin states that he expects to see developed in this district some of the largest gold-producing properties in the world.

F. LYNWOOD GARRISON, with a staff of assistant engineers, among whom are H. L. Mead, H. B. Barling, Lloyd Hoffman, and H. R. Griffin, has sailed for Barranquilla, South America, where a steamer has been chartered to meet the expedition, which will later land at Caceres, near the property of the Breitung Mines Corporation, and as soon as camps can be established Mr. Garrison and his crew of engineers, drillers, and laborers will begin the work of thorough exploration of the company's dredging ground.

Book Reviews

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

COMMERCIAL HANDBOOK OF CANADA, 1913. HEATON'S ANNUAL. By Ernest Heaton and J. B. Robinson. 400 pp. Heaton's Agency, Toronto, 1913. For sale by the *Mining and Scientific Press*. Price $1.

This differs from the ordinary year-book, in that it is devoted to matters of business. Especially useful are the chapters on Canadian commercial regulations, customs, and transportation.

AMERICAN MINE ACCOUNTING. By W. H. Charlton. 367 pp.; ill. McGraw-Hill Book Co., New York, 1913. For sale by the *Mining and Scientific Press*. Price $5.

Though the keeping of accounts is one of the most important phases of the business of mining, and one in which considerable sums can easily be lost or gained, it is the topic on which the least amount of literature has been available. A few books by English authors have appeared, but the methods described are so little in accord with modern American practice as to be of little service, while the discussion of the subject by American writers has generally been confined to the operations of a single company. Mr. Charlton has done a real and valuable service, therefore, in gathering together examples of methods covering a wide enough variety of work to fairly cover the field. The methods of the Oliver Iron Mining Co., the Ojibway Mining Co. (native copper), Utah Consolidated Mining Co. (copper mining), Calumet & Arizona Mining Co. (copper smelting), Utah Fuel Co. (coal mining and coke making), and the Portland Gold Mining Co. (gold mining and milling), are described at length and illustrated with blank forms. A chapter on recording engineering and geological data concludes this book, which is the best we have seen upon mining accounting, and is one which should be of wide interest and service.

MINING ENGINEERS' EXAMINATION AND REPORT BOOK. By Charles Janin. Part I, 94 pp.; Part II, 58 pp. For sale by the *Mining and Scientific Press*. Price $2.50.

Mr. Janin has done useful service in gathering together so compact and useful a compilation of data bearing on the determination of the worth of a mining property. Books of the sort commonly devote too much space to the field of the author's experience and include too much that can easily be obtained from any good civil or mechanical engineer's pocket-book. Mr. Janin's wide experience in the examination of mining properties has evidently well fitted him to select that which is most necessary, for he has included only 'live wood' in the matter he presents. For the same reason, evidently, he has made the book of a size and weight which permit it to be conveniently carried in the coat-pocket, while Part II is intended to serve as a supplementary field note-book from which the final report can easily be prepared. Of great convenience to engineers engaged in examination work, the book is likely to prove equally or more useful to owners and prospective purchasers of mining properties as a concise and accurate summary of the facts necessary in determining the worth of a prospect or mine. Too often the claim or prospect owner is unable to attract the attention of the possible investor merely through ignorance as to what facts are necessary for the business man to form a judgment as to whether the property is worth careful examination. The recent graduate should abstain from attempting the rôle of consulting engineer during his first years of work, but may profit greatly by devoting careful attention to the business side of mining, as a preparation for later work. To all such this book, or others like it, will be extremely useful as an indication of what is most significant and a guide to the determination of necessary facts. For the convenience of those who may care to use Part II as a field notebook, it is sold separately at 50c. The book merits popularity.

SURFACE WATER SUPPLY OF THE UNITED STATES, 1911. PART I. NORTH ATLANTIC COAST. By C. C. Babb, C. C. Covert, and R. H. Bolster, under direction of M. O. Leighton. Water-Supply Paper 301. P. 221; ill., maps, index. U. S. Geol. Survey. Washington, 1912.

MINERAL RESOURCES OF MISSOURI. Pp. 22. This is a neatly illustrated vest-pocket pamphlet issued by the Missouri Bureau of Geology and Mines, illustrating the wealth of mineral to be found within that state. It is an excellent example of the high-class advertising a geological survey may do for a state.

IOWA GEOLOGICAL SURVEY, ANNUAL REPORTS, 1910 AND 1911. WITH ACCOMPANYING PAPERS. P. 1214. Ill., index, maps. Des Moines, 1912. This, constituting the twenty-first volume in the present series of reports issued by the state of Iowa, is the first carrying the name of G. F. Kay as State Geologist, and is a fitting companion to the twenty excellent reports issued under administration of the late Samuel Calvin. The body of the report consists of a monograph on the underground waters of Iowa, prepared by W. H. Norton and assistants, based upon twenty years of consistent study, first at the expense of the state alone, and later in coöperation with the U. S. Geological Survey. It is the most complete study of its kind issued by any state, and makes it possible for the cities and towns of Iowa, as well as individuals and corporations, to determine with a minimum cost, the possibility of securing adequate water supplies from underground. It is not too much to say that the underground structure of no area of equal extent has ever been studied with equal thoroughness, and aside from the light thrown on water problems, material aid to solution of other questions is afforded. The report is not only well prepared but well printed, and the two colored geological maps that accompany it are models of clearness. Prefacing the report is a brief statement covering the mineral production of 1909 and 1910, prepared by S. W. Beyer, and excellent though out of date. The administrative report by Mr. Kay makes it evident that the new State Geologist has a thorough grasp on the essential problems of the Survey. The whole volume illustrates the benefits that flow from continuous maintenance of a non-political organization for the study of the mineral resources of a state. The amount of money available for the work in Iowa has always been small, $5000 to $10,000 per year, but the work has not been interrupted for twenty years and the benefits have been cumulative.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

NATURAL GAS in western Canada costs 33 to 40c. per 1000 cu. ft. to deliver, and sells for $2 per 1000 cubic feet.

PLACER-MINING in British Columbia has produced $71,639,103 to the end of 1911. There are no dredges at work, all attempts at this method of working having failed.

BELT CONVEYORS at many mills pass under circular magnets, 18-in. diam., which extract drill-steel hammer heads, and other articles dangerous to crushers, from the ore.

ERUPTION of Mt. Katmai, in Alaska, in May 1912, caused much ash to be scattered over the adjacent territory. The air also became quite acid, resulting in the extermination of all mosquitoes.

CORLISS inlet-valves were not at first used on air-compressors, the use of poppet valves being almost universal. It is only of late years that the advantages of the Corliss inlet-valve, both as regards efficiency and durability, have been recognized.

VACUUM-FILTER cycle at Yuanmi mill, Western Australia, is as follows: Filling filter-tank, 4 min.; forming cake, 40 min.; emptying filter-tank, 4 min.; running in wash-solution, 4 min.; washing, 50 min.; emptying wash-solution, 4 min.; discharging cake, 10 min.; total time of operation, 116 minutes.

SAND for concrete is being shipped from Seattle, Washington, to Honolulu, Hawaiian Islands, as there is no suitable sand on the islands, which are of volcanic origin and surrounded by coral reefs. Many volcanic rocks which are low in silica and high in magnesia, lime, and alumina, tend to decompose, like pyrite in building stone, and are therefore not suitable for concrete work.

GOOCH FILTER TUBES are subject to breakage, especially when a strong suction is used, and may be effectively replaced by first boring a 7/8-in. hole half way through a No. 7 rubber stopper and then reaming or burning it to an exact fit with a hot crucible. The broken stem of an old funnel inserted in a smaller hole completes the device, which is convenient for filtering liquids which will not affect the rubber.

ORE of the Falcon Mines, Ltd., property, in the Blinkwater district of Rhodesia, contains copper and gold worth $14 per ton, and 15,000 tons per month is to be treated by crushing with 36 Nissen stamps, concentrators, sintering plant, blast-furnace, and converters. Near the mine is a good supply of iron and limestone for fluxes, and water. The new plant should be ready for work at the end of the current year.

GYPSUM has long been mined and calcined in Iowa, being derived from a small area of buried Peruvian rocks in Webster county. It is now announced by the Iowa Geological Survey that a second body of gypsum has been found, this time in Appanoose county. The rock is of good quality, is 5 ft. thick, and is overlain by 5 ft. of anhydrite. It lies at a depth of 550 ft., presumably in Mississippian rocks, and was discovered by drilling.

BUCKET elevators are used to a large extent at Broken Hill. At the Junction North mill, the following is the experience: In an elevator raising ordinary wet table feed, running at 353 ft. per min. with a 24-in. head pulley, the top of hood requires to be at least 3 ft. above the pulley; the delivery should be 18 in. below the bottom of head pulley; while the front of hood should extend 30 in. from face of pulley, then there will not be 50% of the material elevated returned to the boot, as is often the case. All the elevators scoop up the feed from the boot, and there is rarely any trouble through buckets jamming at the bottom. A properly designed elevator takes comparatively little power, causes no trouble, and can be built quite cheaply. The best method is to support the head drum and gearing independently, and then the housing can be of light material.

OXYACETYLENE outfits have been ordered by the New York Fire Department, following the experience in cutting with a hack-saw the heavy steel bars which guarded the windows of the Equitable building, in order to rescue men in the cellar. With the temperature near zero the hack-saw is too slow, especially for the man whose life depends on the bars being sawed before the fire reaches him. This is supposed to be the first instance of these outfits being used by fire departments.

SLIME concentration system at the Junction North mill, Broken Hill, consists of the slime feed-elevator, having two belts with 6 by 12-in. buckets, spaced 10 in. centres, and travelling at 400 ft. per min., delivering to a 7-ft. cone settler, the spigot from which feeds a Wilfley table. The overflow goes to a series of V-shaped settlers, the overflow from which runs to six large rectangular settlers, while the spigot from each flows to a 5-ft. diam. settler feeding a slime vanner, of which there are eight, running at 220 r.p.m. with 3/4-in. stroke. They treat 1500 lb. per hour, and produce a 68% lead concentrate. The Wilfley table treating slime from the settler produces 280 lb. of 72% lead concentrate per hour.

TASMANIA gold mine, consisting of 532 acres, situated 27 miles north of Launceston, produced during the quarter ended September 30, 1912, 13,602 tons of ore yielding $91,000, making the total to date 969,710 tons, and $15,257,000. The mine and mill employ 433 men. Water has given a great trouble at this mine, and pumps capable of dealing with 7,000,000 gal. per day, from a depth of 2000 ft., have been installed. The plant is divided into three sections and consists of compound condensing engines made by Hathorn, Davey & Co. of England, having cylinders 50 and 108 in. diam., with a 120-in. stroke, steam pressure being 150 lb. The quadrants are built of steel plate, blocked with pine, the main bearings being 18 in. diam. and 24 in. long. The spear rods are each 22 in. sq. and 37 ft. long, and the pump plungers 20 in. diam., there being 8 suction and 8 delivery valve-boxes to each plunger.

PROTECTION of mills by standpipes and hose largely depends upon the volume or quantity of extinguishing water as contrasted with mere velocity and little volume. In the presence of a real fire, water is converted either into steam or passes into the spheroidal state, when it is practically powerless to extinguish. There must be a sufficient volume of water thrown to cool the objects which it strikes below the temperature of their ignition. What is called a standard fire stream means the delivery of not less than 250 gal. of water per minute through a 1 1/8-in. nozzle. This means a pressure at the base of the nozzle corresponding to 45 lb. per square inch. Such a pressure will give a reach of 63 ft. horizontally and 70 ft. vertically where sufficient head room can be commanded. The usual pipe hydrant and hose, with their necessary service pipes which belong to any building equipment, may very properly be supplemented by the fire-bucket, chemical extinguisher, and the sand-pail. The sand-pail is particularly effective where the fires take place where oils, varnish, or other combustible fluids are stored. The sand should be distributed from the pail with a scoop. No mention is made of the large number of proprietary devices which are continually urged upon the attention of careful works managers. Some of these belong properly in the chemical extinguisher class, and may safely be urged where the fire is of electrical origin. Some of them, however, by reason of the released gas which is not a supporter of combustion make the air in a confined room irrespirable by the fire-fighter, and are therefore more of a danger than a safeguard, unless used only in the open air. The tetra-chloride of carbon extinguishers are in this class.

EDITORIAL

ARIZONA mining engineers have joined in the formation of a local society, as noted in our news columns. There is enough engineering talent in the new state to make a highly useful and influential society. We trust that the hopes of the founders may be amply realized.

FIRE destroyed the School of Mines building at the University of Minnesota last week. A state with such extensive interests in mines as Minnesota may, however, be expected to rebuild upon a generous scale. The Minnesota school has done excellent work, and even a temporary crippling is to be regretted.

WATER has been turned into the Los Angeles aqueduct and substantial completion of one of the greatest pieces of public work in the United States is announced. Congratulations are due the engineers not only on the ending of a big work, but upon the freedom from scandal and the high class of technical performance which has characterized the enterprise.

SUGGESTION of Mr. Charles G. Yale for the position of superintendent of the San Francisco Mint, a suggestion recently made, we believe, without his previous knowledge, is exceedingly appropriate if the exigencies of politics are to require a change in the position. Mr. Yale is excellently qualified for the place, and we should be glad to see any honor or promotion come to him.

COMPLETE extinguishment of the land debt was announced at the meeting of the American Institute of Mining Engineers this week by Dr. James Douglas, chairman of the committee having the matter in charge. This satisfactory end of a troublesome matter is due more to the generosity and activity of Dr. Douglas than to any other one man. So long as the Institute can command such service its future is secure.

CALIFORNIA, according to our interesting contemporary, *The Financial World*, is about to spend $25,000 in ferreting out fraudulent mining concerns operating within the state. Unfortunately the announcement in this case is so prompt as to anticipate the facts. The California Miners' Association has proposed that the state set aside the amount mentioned for that work, and it would be an excellent thing to do. With, however, 4000 bills before the legislature and expenditures exceeding anticipated revenues, there seems small probability of the action being taken.

CRITICISM of the United States Reclamation Service by the House Committee on Expenditures in the Interior Department is generally discounted by the knowledge of the active campaign that has been made to discredit the Service. It is easier to believe that the committee has been imposed upon than that Mr. F. H. Newell, Mr. A. P. Davis, and their associates have been seriously at fault. It is to be remembered that in every previous instance the Service, when carefully studied, has been found to be clean and able and its officers have given excellent reasons for their actions. Knowing the men in the Service, and much of its work, we have no doubt that adequate investigation will show the same to be true now as in the past.

MINING companies operating where labor must be imported suffer a serious handicap. To them sickness as well as accident is a serious cause of loss. The whole laboring population being dependent on the one enterprise, and overhead expenses being heavy, demurrage of men as well as machines enters into the yearly balance. Such mines in particular find the addition of a medical man to the staff effects marked economy. It is not so much that the physician cures the sick men; his chief value is in keeping men from being incapacitated. When colored labor is employed, malingering is common, but before the stout asseveration of a 'misery' the ordinary engineer is hopeless. One American company operating in the tropics imported a doctor and required all men on the pay-roll to report daily to him for treatment, or to the shift-boss for work. After about two attempts to fool the doctor, the negroes gave it up. On the other hand, Mr. P. R. Bradley notes that the white foremen and shift-bosses are apt to delay going to the doctor too long, and hence to have a serious break-down with resulting loss of time and expense to the company. This can only be met by requiring regular medical inspections. In this and other ways a company doctor may become an important help. Mine managers can not be expected to know medicine, but they should know enough to observe general precautions and to know when and how to employ a doctor. Such general statements as that of Dr. H. G. F. Spurrell regarding the habits of mosquitoes, of which we print the concluding part this week are of great service to engineers in just this particular.

MEXICAN conditions have changed rapidly in the last week and there is general hope that the triumph of the revolution may at least spell peace. There is general disappointment that the result should have been attained through treachery. Mr. Francisco Madero, however much we may differ as to his fitness for the trying position he has been holding, is conceded to be an honest patriotic citizen who purposed well for his country. General Huerta has shown himself to be an excellent soldier, one who has fought valiantly, and often against odds, for the Government in power, whatever may have been his personal prejudice. We can readily understand how such a soldier may have come to believe that further fighting was useless, and that peace and order were of the first consideration. Of General Felix Diaz we have excellent impressions. Incidentally, he has large interests in mines and considerable familiarity with their operation. The discouraging feature of his triumph is that it seemingly reduces Mexico to a military dictatorship, and that he is apparently the accredited representative of the *Cientificos*. While we believe thoroughly that Mexicans must work out their own salvation, we should regret to see any check in the democratization of the country. One form of government can not be held to be best for all people at all times, but that government is most secure that rests on the broadest basis. Americans generally will watch with the greatest interest and sympathy the efforts of the group now in control to restore to our neighbor peace and prosperity.

A Geological Survey Building

It is with unusual pleasure that we note that in the public building bill passed by the House of Representatives at Washington last Monday provision is made for a building for the United States Geological Survey. We have already discussed at length the need of this building, and, aside from the pleasure that mining men will take in the feeling that the valuable records of the Geological Survey are hereafter to be adequately protected from fire, there is added satisfaction in the evidence afforded by this and other items that the public building bill is not wholly a 'pork' measure. It is right and proper that the Government should own the buildings necessary for the conduct of its business. It is certainly better to pay interest at a low, than rent based upon the high rate that private building owners naturally ask. For many years to come, if not for always, a large public building appropriation is to be expected. The petty politician who gets into Congress has looked upon the matter solely from the standpoint of getting money spent in his district; and his constituents have too often forced him to adopt that point of view. We are glad to believe that the day is rapidly coming when a Congressman can be more independent, when he may work for the common good and treat the business of the Government from a business point of view. The blame for past excesses is by no means all to be assessed to the men at Washington; but the better leaders they prove, the quicker will days of the 'pork barrel' end.

The Geological Survey has given a third of a century of service to the country, and it has been devoted service of high class. The organization has been an important factor in the rapid development of the West, and now that the Nation is taking serious thought of its public lands, the field of activity for the Survey and the Bureau of Mines will be rapidly enlarged. Good service, effective business-like administration, is only possible when the men are given suitable quarters and facilities. The two and a half million dollars which it is proposed to expend on a modern office-bulding is none too much, and will, we believe, prove an excellent investment. The members of the House committee have done well, and we hope the Senators will follow their lead.

Statistics and Ethics

Good statistics are vital to sound industrial development. They not only afford a solid basis for correctly judging past performance, but the surest known means of estimating the future. In the United States the best statistics for the mineral industry as a whole have come from the United States Geological Survey. There are those who maintain that it is no proper part of the work of the Geological Survey to publish figures of production, and our New York contemporary, the *Engineering and Mining Journal*, has, at times, been especially insistent upon this point. For our part, we have felt that much at least of this work belongs properly to the United States Bureau of Mines, but, regardless of who may do the work, accuracy and promptness in publication are clearly of first importance. In order to secure the latter, the Geological Survey has been in the habit of preparing brief advance statements which are furnished free of cost to the press and which are widely used. The annual estimates of production issued the first of the year have been especially well received, and, on the whole, have proved surprisingly accurate.

In a recent circular letter issued by the Director of the Geological Survey, the following statement occurs: "The technical papers and journals, whose editors are perhaps best qualified to judge of the value of these preliminary Survey data, were especially generous in the space given to them. One of the leading mining journals, however, even added to this type of approval, in that it printed as of its own compilation, the table of gold-silver production issued jointly by the Bureau of the Mint and the Geological Survey, but only slightly changed. In other columns of this issue the credit given to the Survey data was incomplete and in most cases entirely lacking, although the data were generally used with very slight modifications. In one case, an obvious error in the Survey statement was repeated, though with sufficient change of form to make it appear altogether original with the technical paper, a device frequently used in this issue. Whatever might be said regarding the withholding of proper credit concerning official government statements, it is certainly unfair to the reading public not to fix the responsibility of authorship for all parts of a statistical statement."

Thanking the Director for our part of the compliment addressed to technical journals, we join him heartily in condemnation of the use without credit of the figures collected by the Survey men. In our own review number issued January 4 we printed, along with other statistical matter, the detailed figures of gold and silver production in the United States, crediting them, as we were glad to do, to the courtesy of the Directors of the Geological Survey and the Bureau of the Mint. A week later the *Engineering and Mining Journal* published the identical figures except for four minor changes due possibly to errors in transmission. There was, however, nothing to indicate that the statistics had not been independently collected by the reputed author of the article in which they appeared, one of the regular members of the staff of the *Engineering and Mining Journal*. The distinguished metallurgist who edits that journal is at the same time secretary of the Mining and Metallurgical Society of America. This society recently printed the preliminary draft of a code of ethics, of which Section 24 reads as follows: "The engineer should take care that credit for engineering work is attributed to those who, so far as his knowledge of the matter goes, are the real authors of such work." Apparently, as to the control of the *Journal's* policies, the editor in question is in the position that Lincoln once averred himself to be—of having "no pull with the administration." We have repeatedly insisted, and the case in point illustrates the need, that technical papers should be owned and controlled by technical men. If an engineering paper is to represent engineers and be more than a lure for advertisers, it must be conducted along lines that engineers recognize as ethical. In practice this often fails to be true when the engineer is the employee rather than the employer.

The Institute Election

At the business meeting of the American Institute of Mining Engineers held in New York last Tuesday, the new constitution was adopted with only six dissenting votes. The amendments proposed by Messrs. C. R. Corning and George C. Stone were also carried by a substantial majority, but the proposal for creating an order of fellows was defeated. In consequence of the substantial vote for the new constitution and the new order of business there was no need to count the vote for members of the Council, and election of a secretary devolved upon the new board of directors. They endorsed the action of the nominating committee and chose Mr. Bradley Stoughton for that position.

Of the two ballots for directors, the green ticket won by a substantial majority. This, it will be remembered, differed from the official ballot in that a definite selection had been made for each office and all those now serving either in the Council or as a director, were included. The nominating committee, in providing a better geographical distribution, had omitted some of the names appearing on this ballot. The winning ticket, as also that which lost, was an excellent one. Every man upon it is an engineer distinguished in the profession and for his high character. In the whole contest there has been, fortunately, nothing personal, and we, who advocated the other ticket, offer our hearty congratulations and good wishes to the winners. We are frank to say that we believe the majority of the members merely voted the ticket that was easiest; the one ready prepared and which they ran no chance of spoiling. That the new constitution was adopted by so overwhelming a vote indicates, we believe, that the members favor a new regime. The action of the directors in selecting Mr. Stoughton as secretary indicates that they are in accord with this spirit and not among those who worship at the shrine of Dungara, the "God of things as they are."

Principles of Mine Valuation

By James R. Finlay

*Almost all enterprise is based on valuation of some kind. Practically all transactions in mining property, whether in stocks, bonds, or actual ownership, are based on some kind of an appraisal. If you expect to be employers instead of employees you should begin at once to study the factors which give value to things. You cannot buy intelligently nor sell intelligently until you know how to form an estimate of what a given property is worth to you, to the man you are dealing with, and to anyone else who might be brought in.

Engineers and Business

This generalization has no more application to mining than to any other form of business; but it certainly does not apply to mining less than to other forms of business. I think that no more unfortunate idea is taught to young mining engineers than that they are to consider themselves merely as professional men, like doctors or ministers. I would not speak of this if such an idea had not been cultivated in certain quarters. It is true that some mining engineers are employed to do technical work as referees between conflicting interests. Professional honesty is, of course, an absolute essential, but the honesty of a mining engineer is the honesty of business and of common sense. It is not in the least desirable for a mining engineer to avoid business transactions; on the contrary, he should go into them as soon as possible and study the subject in every possible way. I do not see how any man can make a success of mining who does not realize that it is a strictly commercial business; that the only result to be sought is commercial success; that the only scientific and technical attainments that are worth anything are those which contribute to commercial success. Attainments of a different character are, of course, worth while; but they are valuable to a mining engineer because he is a man and a citizen, not because he is a mining engineer. They would be equally valuable in every kind of profession. Success in business is measured in money. Technical skill is efficient only if it pays. One can judge of the value of technical excellence only if he is prepared with a knowledge of what constitutes the money value of the results.

Undoubtedly this view of the mining business, or profession, has been gaining ground in our universities and technical schools. Formerly, I think, education was considered to be merely a training in principles. Technical training was a discipline in the science of action (I coin the expression), an exposition of the principles of doing things. Whether it was worth while, in dollars and cents, to do a thing was to be found out later in actual business. Now I think it is recognized that, while making money is of course a matter of actual occupation in business, there are certain general principles underlying the value of things, which are well worth study. This is the study of political economy, which is cultivated in all our universities. The mining engineer sooner or later comes into contact with this subject and is bound to find it interesting and important. I shall try now to advance a few ideas about the valuation of mines, which I think are basic enough to come under the head of general principles.

What Fixes Prices?

The first thing to which I wish to draw your attention is the general subject of valuation. What is it that causes a price to be fixed for commodities or properties? In general, there are two methods of fixing prices; one is the empirical method, and the other, the constructive. The empirical method of fixing prices is simply to obtain a record of facts—of transactions. A man will assume that a town lot is worth $100 because he finds that people have bought and sold similar lots for $100 apiece. Nearly all commodities of a retail nature are valued in that way, and it is perfectly logical that they should be, because each actual transfer is a bargain between the buyer and the seller, theoretically at least. The man who sells for a certain price does so because he believes he can do it profitably. On the other hand, the man who buys computes in the same way. Consequently wheat, iron, and copper, as commodities, are valued empirically by merely ascertaining what sales are made; and fluctuations of price are established by supply and demand.

The constructive method is that which determines the value of commodities in a more or less scientific manner; builds up logically an estimate of what it properly should be worth. This naturally applies to properties which are dealt in only occasionally, for which there is no precedent of an actual sale of the equivalent thing. You will easily see that mines belong to that class of property.

Fundamental Factors

Hardly any two mines are exactly alike; therefore you cannot say logically that because one mine is worth $1,000,000, another mine is also worth $1,000,000; at least you cannot say so until you have gone through the factors which give both properties value, and have found that they are identical. It is to those factors which do give value to mines that I wish to call your attention now. I have always supposed, and I think that nearly all mining engineers agree with me, that there are three or four fundamental factors about a mining property which determine its value. These are:

1. The average cost of securing the product of that mine.
2. The average sale price of the product.
3. The rate of production of the mine.

*A lecture delivered before the Department of Mining, Columbia University, December 2, 1912, and published in the *School of Mines Quarterly*.

4. The time for which the output can be maintained.

I do not intend to go into detail as to any of these factors, but to point out some things which I think are worth considering, in the hope that later you will think about them and learn the details for yourselves.

In regard to the average cost: In the case of going concerns, that average cost can be obtained empirically by simple reference to the books; to what has actually been done on the property. That seems and sounds exceedingly simple. As a matter of fact it is not easy. I made the mistake once of thinking that it was. I bought a mine in Joplin, Missouri, to be specific, on a record of its working cost for six months. The reason I did not go further back was that older records were not to be had, and also because during this particular six months the property had reached a substantial basis. I figured that concentrate from that mine could be produced for about $20 per ton, and I also estimated that the property should produce so much ore, and that the price would be a certain figure. It happened that developments proved that I was right about the price and quantity of ore on the property, but they also proved that I was wrong on the question of costs. It cost us nearly 75% more to produce concentrate from that ore than the record of the property showed. There were times when we produced concentrate for $15 per ton, but that was not representative of the whole period of working the mine. I think you will find today that a great many of the cost statements given out by different companies for fixing the value of their stocks are only temporary or occasional costs, and will not stand analysis.

Capital and Operating Accounts

Then there is another factor in which people deceive themselves, unconsciously, but in the simplest and most obvious way imaginable. They keep on doing it, always have done it, and I suppose always will do it. That is, by failing to see the relation between expenditures that are for plant and those for keeping it going. In keeping books it is very easy to say that the construction of a building, the remodeling of a mine, or the building of a new mill, is something that will not happen again, that it belongs to the property and not to the operation; to a certain extent that is true, but it is a fact, which I have verified by looking up a great number of mines, that the so-called operating costs are ordinarily not more than 60 to 80% of the total cost. Until a mine is shut down, there is always some expenditure to be undertaken which a bookkeeper may think will not be repeated, that it belongs to the plant, but these things keep occurring so constantly that one who is figuring on costs must count on them.

Another thing I believe to be true is that any estimate of cost, or valuation, or anything relating to the future, is a good deal of a guess. One who thinks he can estimate a cost, whether of a going concern or a concern to be started, to a fraction of a cent, or to any fixed amount, is simply mistaken. All you can do is to put a round figure which seems to be pretty near the facts. Of course, the difficulty of estimating costs at a mine which is not yet opened is greater than at a going mine.

The next fundamental factor in forming an idea of the value of a mine is the average price of its product. I will go so far as to say that this is the most important factor to be considered. The literature on this subject, I think, has not done justice to the importance of prices because apparently a good deal of the best thought given to the subject of valuations has been by English engineers who had in mind principally gold mines. Gold, of course, is the only product of mines the value of which is fixed; consequently most of the discussions on mine valuation among engineers have been devoted to the third factor, which I will come to later, namely the uncertainties regarding the amount of ore in a mine and the part that developed ore plays in the estimate of a total valuation.

Valuing Copper Mines

As an example of the tremendous importance of the price of a product in mine valuation, I will cite from my report on the Michigan mines. At the time of that report, the price of copper was 12¼c. per pound. A group of copper mines in Michigan were producing, and had been producing 200,000,000 lb. of copper per year at a cost of 10c. per pound, in round figures. I valued the mines on the assumption that the average price of copper would be 14c. per lb. as against the current price of 12¼c., and I put a valuation of about $70,000,000 on that basis. Roughly, at 14c. per lb. the earnings would be $8,000,000 per year, and the total value of the group would be nine times that, or $70,000,000. You will find that it is a difficult thing in commercial transactions to figure steadfastly on a price that is different from the present price. When I talked about copper averaging 14c. per lb., many said, "That is not the present price, it is 12¼c." Some thought the price might go even lower instead of higher. I think if I had not been prepared by several years' study of that very subject, I would certainly have used a lower figure than 14c. per lb. for the average price of copper. At any rate, the value I put on them was nine times their annual income at 14c. If I had used the current price of 12¼c., their annual income would have been only $4,500,000. As a matter of fact, within less than 12 months after the report was made the price of copper had gone up to 17¾., and the usual proportion of people thought that the price would go still higher, and that this might be the average. If it had been the average, the earnings of these mines would have been nearly $15,500,000 at that price of copper.

Effect of Price Estimates

Now let us look at what these figures mean in terms of the life of a mine. If I had figured that the mines were worth $70,000,000 at a price of 12¼c. per pound, I would have had to believe that the mines, on the average, were good for 40 years' life, instead of about 13 years. If, on the other hand, I had assumed that the price would be 17¾c., in order to make the mines worth the price I put on them, they would have to last only 5 or 6 years. Therefore the

fluctuations of price in less than a year corresponded to an extension in the life of those mines from 5 or 6 years to 35 or 40 years. Here again I am dealing in a mere approximation. I suppose these mines produce about 20 lb. of copper per ton; therefore to get 200,000,000 lb. of copper per year, you would have to mine 10,000,000 tons. Therefore, the figures that I actually used meant that I believed there was 130,000,000 tons of copper ore which could be depended on. That is an enormous amount of ore. Figured roughly, that would mean a lode of solid ore five miles long, of the average width of 12 ft., and 5000 ft. deep; it was actually obtained by projecting the production of the mines and the development of the mines far below their present position. Now if I had to estimate on 12¼c. copper, I would have had to figure on 40 years' life, or I would have had to believe that there were 270,000,000 more tons there than I thought I was justified in believing. On the other hand, if we put the value at 17¾c., I should have had to figure on only 50,000,000 or 60,000,000 tons of ore. Therefore, I say, as affecting the value of mines, the actual fluctuations of price within one year were equal to an uncertainty in the ore production in those mines of more than 300,000,000 tons. An engineer is not likely to make a mistake like that when a mine is so fully developd as these Michigan properties, many of which are worked to a great depth, are well managed, and have their outlines very well shown. He could, however, easily make just as important a mistake as that in figuring on his average price of copper.

Average Price of Copper

As a matter of fact, I do not think the 14c. price I used was an accurate figure. I believe that copper will average more than 15c. per pound, taking into view the development of the business, but 14c. was as far as I thought I could go. I do know that mines have been valued within the last five years on prices estimated all the way from 12 to 20c. Just imagine what a difference that makes in the estimated value of those mines! I know a very important mine in Mexico, the organizers of which believed that copper would not average less than 20c. per pound. I know of mines, on the other hand, that are being valued on an expectation of 12½c. per pound.

I ran against the same difficulty with another group of mines during that same Michigan study. In the iron mines I assumed a price for iron which happened to be almost the same as the price for the year 1911, which was a dull year in the iron business. In this case, however, the price, instead of going up, as the price of copper did, went down about 50c. per ton the next year. Now the margin of profit for those iron mines, during the period that I figured on was just about $1 per ton, so that if you take off 50c. per ton you cut the profits in two. Of course, during all this last year, I have been exposed to a good deal of criticism by the iron miners, because they say I assumed a wrong price. While it may have been wrong for the year 1912, I notice that prices for the year 1913 have been fixed lately and at a figure very close to my average, in fact, almost identical with it if certain reductions in freight rates be considered.

In both the iron and copper calculations, I have been asked a great many questions as to how I arrived at the prices I assumed. Here there are certain evidences which can be used as guides, and are well worth studying. One general fact about the prices of all mining products is that they vary in cycles or in waves, irregularly of course. If, after a period of high prices, you find that prices are definitely going down and reach a new level, it is pretty safe to believe that the lower level of prices will continue several years. On the other hand, after a period of low prices, when once the metal rises markedly, it is pretty safe to assume that it will stay at a higher level for several years. Those fluctuations are things well worth studying. It is a matter on which you cannot at once form opinions.

Present Price and Average Price

The valuation of a mine, while in the long run it depends on the average, is influenced a good deal by the present price. If you have a copper mine that is going to last ten years, and you expect 18c. copper for three years out of those ten, it is a matter of considerable consequence to your property whether that 18c. price comes during the first three years or during the last three years of the life of your mine. If it comes in the first three years you will get your profits and may invest them, perhaps in other directions, and the interest on that money for the following years will be worth a great deal to you. I must confess, in regard to the question of profits, that I was wrong when I wrote 'Cost of Mining,' in laying too much stress on average price. I now believe the public is right when it puts a higher value on properties during periods of high prices for metals. That is merely an assertion which I offer you to think about. It is a curious thing, which anyone can observe by watching stock quotations, that the prices of mining stocks vary almost with the price of the metal itself. When copper metal goes down, copper stocks go down. I always used to think that this was illogical, but I have come to the conclusion now that the public, which bases its valuations on present commercial conditions, has been more logical, on the whole, than the mining engineer.

Life of Gold Mines

The question of the life of a mine is not to be overlooked by any means. In many cases that is the most vital factor, particularly in the case of gold mines, because fluctuation of price does not then enter into the problem. Take, for instance, the Goldfield Consolidated. That property has made a spectacular showing in dividends, but it has always been recognized that its life was uncertain; and now, in spite of the fact that for two years it has been paying very large dividends, the price of the stock has been so low that the dividends have equalled 50% on its market value. Recently the stock has been selling for $1.75 per share; the actual dividends paid during the past year have been $1.60 per share. Now, if the mine were valued in the way some copper mines are valued, paying dividends, say, at the rate of 6% of the selling price, the price to be put on Goldfield

stock would be $20 per share. In that mine the whole question centres on the length of its life. I speak of it because this is so contrary to usual experience. I do not know of any other case in which the public has been warned, or has become convinced of a mine's exhaustion so long in advance.

On the other hand, there are some mines with an expectation of long life which cannot show any ore reserves at all. Certain mines at Tintic, Utah, which I should be willing to value on an assumed life of five or ten years, do not show ore reserves for even three months. The reason is that the form of the orebodies is such as to prevent ore reserves from being developed. The ore occurs in an immense mass of limestone, through which mineralizing solutions have passed, and have been diverted by various intersecting fissures. The orebodies are irregular, sometimes small and sometimes swelling to large size; sometimes they go down vertically four or five hundred feet, forming a pipe, then abruptly go off horizontally for four or five hundred feet, and then up again, then shooting to the right or to the left. If nothing were known about the persistence of these orebodies, one would be justified in being exceedingly skeptical about the future; but the experience of 30 years has shown that these deposits, in spite of their irregularities, are exceedingly persistent. In making his valuation the intelligent engineer will, of course, consider this fact a pronounced asset.

Russia's Gold Century

ST. PETERSBURG CORRESPONDENCE

This year is the centenary of the publication of the ukase by which all Russian subjects were allowed to exploit gold vein deposits; for until 1812 the production of gold was a state monopoly. Although it was well known at that time that the wealth of Russia in gold was almost inexhaustible, the annual production by the government amounted to only an insignificant figure. In the first years of the rise of the gold-mining industry it amounted to no more than about $10,000 per year, inclusive of all three known gold areas at that time; the Urals, where gold was found in 1744; the Kemsky district; the Archangel Government, in 1745; and at Altai. It was only at the beginning of the nineteenth century that the annual production of gold reached as high as $250,000.

The permission then extended to private persons to exploit gold deposits considerably extended the Russian gold industry; and it began to develop with great rapidity from 1819, when private people were allowed to exploit alluvial gold as well. Thus in the five years 1816 to 1820 the gold produced was worth $924,000, and from 1821 to 1825 it had already nearly reached $7,000,000. The increase continued and the following five years the output was $19,000,000. In the period 1848 to 1855 the production of gold reached $88,000,000. At the end of the seventies the average annual production reached the respectable figure of $27,000,000. In the year 1911 the quantity of gold extracted in Russia amounted to $33,540,000. But a large quantity of gold produced in Russia now is not registered. Thanks to the difficulty of superintendence in such out-of-the-way places as Siberia, no small quantity of gold when it is extracted falls into the hands of poachers, who clandestinely manage to transfer it to other countries.

The United Verde Smelter

The United Verde Copper Co. has under construction at Clarkdale, about six miles from the present plant at Jerome, a new smelter of approximately 3000 tons capacity per day. For the following details concerning the new construction we are indebted to the *Jerome News*. The plant will consist of four blast-furnaces, 48 in. by 26 ft., three reverberatory furnaces, 19 by 100 ft., and five 12-ft. converters, together with the necessary receiving and storage bins for ore and coke, a well equipped sampling mill, ore-handling system, dust chambers, and stacks.

Most of the power for operating the smelter will be supplied from waste heat boilers, connected with the reverberatory furnaces. The main power plant will be equipped with one Southwark compound blowing engine; one Rateau-Smoot steam turbo-blower; one Diesel double-unit six-cylinder oil engine, driving through rope transmission; one No. 11 Root blower, 300 cu. ft. per revolution; two No. 11 Root blowers, 300 and 400 cu. ft. per revolution respectively; one 300-cu. ft. blower, driven by a reciprocating engine; one Westinghouse-Parsons steam turbine generation unit, 500 kva., A.C.; one 1500-kva. unit; and two Weise condensers, capacity each, 41,000 lb. steam per hour, with auxiliary apparatus.

The shops will be equipped with modern machinery. The warehouse and main buildings will be of steel structures, designed with a liberal allowance of operating space. Approximately 10,000,000 brick and 8000 tons of steel will be used in the construction of this plant. A modern brick plant, to make the brick, is in the course of construction. The material will be handled in and around the plant by a modern industrial system, including the latest design of electric locomotives, conveyors, and trams.

The townsite of Clarkdale will be controlled by the United Verde company. It has been laid out on strictly modern and sanitary lines. The buildings have been carefully designed with due regard to climatic and other conditions. The fire and water supply system has received careful attention. A 40,000-volt transmission line, connected with the Arizona Power Co. mains, supplies the necessary power for construction requirements.

The new smelter and townsite are connected with the standard-gauge Verde Valley railway, extending up the Verde valley a distance of 40 miles, and connecting with the Santa Fe, Prescott & Phoenix railroad at Cedar Glade. This gives the new townsite and smelter a decided advantage in transportation facilities over the old smelter and Jerome narrow-gauge connection. It has been estimated that it will take approximately two years to complete the new plant.

Regrinding at the Pittsburg Silver Peak Mill

By S. J. Kidder

In the treatment of comparatively low-grade ores the rather high cost of all-sliming has in some instances made this procedure of doubtful value. On the other hand, there are numerous cases in which careful classification of the sand product, followed by the regrinding of the coarser sand particles, will result in a material saving above the cost of regrinding. The latter condition obtained at the Pittsburg Silver Peak mill, where crushing to 30-mesh with 120 stamps was followed by amalgamation, separation into sand and slime, direct treatment of the slime in Merrill slime-presses, and leaching of the sand.* Repeated screen analyses of the sand residue showed that the material remaining on 80-mesh, amounting to from 52 to 56% of the whole, contained 85 to 90% of the total value in the residue.

Screen Analysis of Sand Residue

Mesh.	Per cent.	Value.
On 40	22.82	$1.83
60	29.32	1.00
80	10.05	0.80
100	10.47	0.59
150	7.75	0.28
200	10.72	0.18
Through 200	8.87	trace

By careful hydraulic classification, 50 to 60 tons per day of the coarsest sand is now returned, by means of a bucket elevator, using 6 by 10-in. buckets, to a 13-ft. Akins classifier feeding a 5 by 18-ft. Allis-Chalmers chain-driven tube-mill. The discharge of the tube-mill undergoes secondary amalgamation before being returned to the main classifying cones. As an aid in regrinding the fine sand, and at the same time with a view to increasing the mill tonnage, one battery discharges directly to the Akins classifier through a 4-mesh screen. The Akins classifier has worked for six months with no repairs other than increasing the size of the truss rods from ⅝ to ¾ in. The mill was originally lined with 4-in. silex, which lasted six months on the hard quartz which is being reground. Mine quartz, sorted out and sacked on the crusher-room floor, is used almost exclusively in place of pebbles. The quartz at the lower tramway terminal is spalled to the right size for feeding into the tube-mill spiral on the feed end of the mill. The quartz is much harder than that in either Tonopah or Goldfield ores and stands up well in the tube-mill. The screen analysis of the discharge pulp is practically the same as when using all Danish pebbles. For elevating the sand and for regrinding, 4 hp. is required, and 49.5 hp. for operating the Akins classifier and tube-mill. The total saving by regrinding the coarser sand amounts to from $1200 to $1600 per month. The additional milling cost on account of regrinding amounts to 3.9 cents per ton of ore milled, as follows:

Labor	$0.004
Supplies	0.015
Power	0.020
Total	$0.039

On account of the additional slime produced by regrinding, and an increasing amount of slime in the ore, it was necessary to increase the filtering capacity of the plant. This was done by enlarging the three 64-frame Merrill slime-presses by the addition of 22 frames and plates to each press. Arrangements were made for sluicing the enlarged presses from both ends instead of from one end as formerly. The cost of installing the 66 additional frames was considerably less than three-fourths of one 64-frame press. Each press was out of commission but from 24 to 32 hours in making the extensions. The only concrete required was for the three piers supporting the rear end of the presses, and no additions were required to the building.

The total operating costs for 1912, during which time 172,482 tons of ore was milled, was as follows:

	Labor.	Supplies.	Power.	Total.
Stamping	$0.067	$0.092	$0.155	$0.314
Amalgamating	0.039	0.004	0.001	0.044
Tube-milling	0.001	0.013	0.012	0.026
Neutralizing and settling	0.028	0.053	0.002	0.083
Leaching and sluicing	0.047	0.079	0.014	0.140
Filter-pressing	0.035	0.061	0.018	0.114
Precipitating	0.004	0.036	0.001	0.041
Refining	0.018	0.028	0.001	0.047
Assaying	0.016	0.012	0.003	0.031
Water service	0.024	0.016	0.027	0.067
Heating	....	0.003	....	0.003
Superintendents and foremen	0.067	....	....	0.067
Total direct operating	$0.346	$0.397	$0.234	$0.977
Pro-general	0.034	0.060	....	0.094
Suspense account	....	0.050	....	0.050
Total operating, 1912	$0.380	$0.507	$0.234	$1.121
Total operating, 1911	$0.370	$0.477	$0.186	$1.040

The slight increase in operating costs in 1912 over 1911 is to be explained: (1) by an increase of 4.8c. per ton of ore milled in the contract price for power; (2) by a decrease of 10,000 tons in the amount of ore milled for the year, due largely to labor conditions in the summer months; and (3) by an increase in the suspense account of 5c. per ton, to pay for the improvements made during the year.

Treatment costs at the Yuanmi mill, Western Australia, the ore consisting of kaolinized material, mixed with a hard silicious matrix, are as follows:

	Cents per ton.
Rock-crusher	11.6
Ore transport	4.9
Milling	54.3
Fine grinding	54.5
Vacuum-filter	8.6
Precipitation and clean-up	8.9
Disposal of residue	4.4
Total cost per ton	$1.472

*For further details of the plant see *Mining and Scientific Press*, May 8, 1909, and Feb. 10, 1912.

The Habits of Mosquitoes—II

By H. G. F. Spurrell

*The life history of the mosquito has now been traced from the egg to its close, and the dread with which these insects are generally regarded has so far been left unexplained.

This is because the mosquito under normal conditions can inflict no greater injury on man than a few irritating papules on the skin. It is important to remember this. A mosquito can only become dangerous by feeding on the blood of some person who is in a particular stage of some infectious disease. If a culex mosquito happens to choose for its victim a person suffering from filariasis, and bite him during the night, it will probably become infected with the microscopic worms which are then active in the blood immediately under the skin. If a stegomyia mosquito ingests the blood of a patient suffering from yellow fever during the first three days that the fever is running its course, it will become infected with the germ of yellow fever. An anopheline mosquito biting a person with malaria in his blood during the right phase, will, in the same way, become infected with malaria. These will serve as examples.

Period of Infection

Supposing that a mosquito after becoming infected as just described, retires for the requisite three or four days to digest the diseased blood and, as soon as she is ready to feed again, bites some person who has not already acquired that particular disease, it might have been expected that she would infect him with it. On the contrary, she can do him no more harm than a mosquito which has never tasted blood before. The germs of the disease mentioned are not carried about in the mosquito's proboscis like bottles of poison in a man's pockets. They are living creatures, each with a life history of its own, quite as varied as that of the mosquito itself, and before they are ready to pass into the blood of another human being, from the body of the mosquito, they have to complete, in that environment, a phase in their own cycle of existence comparable, though of course different, to the larval stage of the mosquito which has to be lived in the water. The time necessary to complete this development in the case of the filaria is from 16 to 20 days, in the case of yellow fever about 12 days, and in the case of malaria about 8 days. Until this period has elapsed the mosquito may bite but will not infect her victim with the disease she carries. After the germ has had time to mature it will pass, each time she feeds, from her proboscis into the blood of the person she bites and there start another stage in its life-cycle the results of which, to the person who harbors it, may be fever or even death. In some diseases, notably in malaria, every stage in the parasite's development can be followed by means of the microscope, from the time when it makes its way through the wall of the mosquito's stomach, to the time when it reaches the salivary gland and is ready to be injected into the blood of the next person whom the mosquito bites. The mosquito, from the time when this happens, until the end of its life, is a danger to mankind. These are not high probabilities based on general observations, but facts ascertained by careful and often-repeated experiments. Men have exposed themselves in countries where malaria and yellow fever were rife, to every source of infection, except the mosquito, and not contracted the disease. Mosquitoes which had been induced to bite infected persons were then allowed to feed upon the experimenters, who rarely failed to manifest signs of the disease when the known incubation period was over. Other infected mosquitoes have been sent long distances, and set to bite persons who had never been exposed to any other form of infection, and the result was no less convincing. It may make the precise knowledge we have on these subjects appear of greater value if we reflect, that in only too many cases it has been obtained at the cost of the experimenter's life.

Means of Infection

Two questions immediately suggest themselves, namely: Can mosquitoes become infected in any other way than by feeding on diseased human beings, and, can mosquitoes transmit the diseases they carry to other mosquitoes, or to their own progeny? In the case of malaria, at any rate, these questions, so far as our present knowledge goes, may be answered with an emphatic negative. In countries where malaria is endemic, the anopheline mosquitoes draw their infection mainly from the native children. In such places the malarial parasite is early introduced into the blood of every native child, and only those whose powers of resistance are high live to grow up. The adult natives usually seem to have attained immunity, and the parasite, which can easily be demonstrated in 100% of their children, cannot be found in the parents' blood at all. They not only cannot be infected, but do not, like the children, carry infection. Even the children, though their blood may be teeming with parasites, appear to suffer little if any discomfort. Elimination of the susceptible through many generations has produced a strain which is indifferent to a germ that will kill people of unselected ancestry. The stegomyia mosquitoes probably derive the yellow fever infection from a similar source; but what we know at present of this disease lags behind our knowledge of malaria.

Taking the anophelines as typical of the mosquitoes we have to fear, and malaria as the example of the diseases they may transmit, one may venture on a few more generalizations. It is obvious that the mosquito should never for a moment be allowed to usurp the first claim to our attention. Mankind wishes to stamp out malaria and wars against mosquitoes only as a means to that end. So far as mos-

*Continued from p. 274.

quitoes themselves are concerned, our real object is to avoid being bitten not by any mosquito, not even by infected mosquitoes, but by infected mosquitoes which have become infectious. It is only because any given mosquito may be a carrier of disease that war, with no quarter, must be carried on against all mosquitoes.

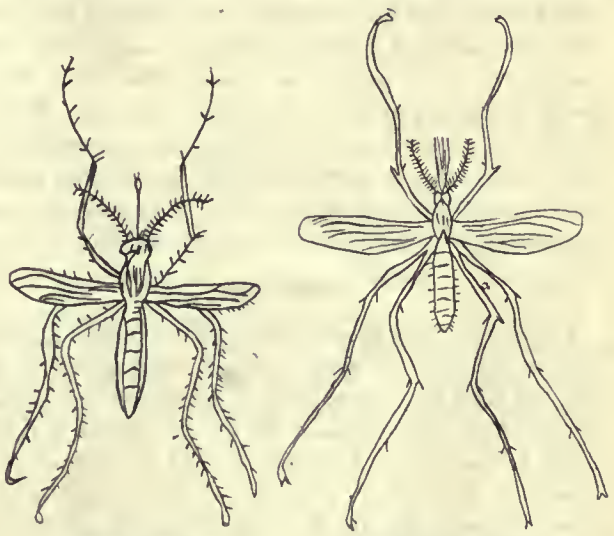
Extermination of Mosquitoes

A study of the habits of mosquitoes shows that it is possible to deal with them in the hope of attaining three totally different, but not irreconcilable ends. We may aim at destroying all mosquitoes, at preventing any mosquitoes from biting human beings, or at avoiding, so far as we can, the possibility of being bitten by infectious mosquitoes. To take these in order: The first is a counsel of perfection. I think most authorities are agreed upon this. "Manifestly, the extermination of the anopheles is a task before which the labors of Hercules pale" (Bullock). "Yet, although complete extermination of mosquitoes is not to be expected, relative extermination of mosquitoes is worth attempting, and certainly much can be attained in this direction by the vigorous use of the now well known measure" (Manson). These measures have been discussed already, for they resolve themselves almost entirely into devices for preventing the mosquitoes from breeding. In such a city as Rio de Janeiro, which is magnificently laid out on a splendid site, the task is comparatively easy. With well built houses laid out in wide streets over a large area, throughout which the drainage and water supply are on the best models, and with inspection carried out and sanitary rules enforced by a strong central authority, mosquitoes may be reduced to a minimum.

There are towns, especially within the United States, where each house-holder is required to make considerable efforts for the public safety and is fined if mosquito larvae are found by an inspector on his premises; but some of the most important measures can only be carried out by a public body. At Athens, for instance, Professor Cardamatis "attacked the state of the Ilissus, a sluggish stream which spreads itself into many wide shallow semi-stagnant pools, the very place for mosquito larvae, further sheltered as these are by the weeds which grow in slow-moving water. He cleaned out the river bed, and by embankments and deepenings narrowed its course and expedited its flow" (Lancet, 30, 9-11). Where such conditions prevail, sanitation must be begun on a large scale before the efforts of private individuals can be effective. Yet, even at Rio I have seen cases of malaria, and yellow fever is not entirely extinct, though Rio is a Paris 'built with second thoughts,' and has sometimes led the way in tropical hygiene. Even in England the anopheles mosquito still survives, though malaria has long disappeared from places where it was once endemic.

Other Precautions

The means which have been successful in making mosquitoes rare in Rio and Havana would, however, be insufficient in cities like Para in the delta of the Amazon, or New Orleans in the swamps of the Mississippi. Here it is necessary, as well, to make the houses mosquito-proof, and by staying indoors from sunset to sunrise to afford the mosquitoes no opportunities of biting. Houses can be made mosquito-proof in two ways: either by screening every door and window separately, or by putting wire gauze around the whole veranda. The latter method is infinitely preferable. I had some experience with screened windows and doors at Para, and found that on the one hand they made the rooms so close that people soon relapsed into the habit of leaving them open; while on the other, it was difficult to keep them all in sufficiently good order to prevent the mosquitoes from finding a way in. Neither of these defects applies to the practice common in the Southern states of having a wide veranda all around the house and screening this veranda. Then with the entrance to the veranda passing through a short passage guarded by double doors, invasion by mosquitoes can really be prevented. There are people who object to the idea of living in a 'meat-safe,' but personally I am content to be where I can sleep without a mosquito net, and eat my food without an admixture of flies.



TIGER FEMALE. (Carries yellow fever.)

ANOPHELINE FEMALE. (Carries malaria.)

Avoid Being Bitten

Lastly, those who, like many of us in West Africa, have not mosquito-proof houses, or are not able to stay inside them from sunset to sunrise, can at least try to avoid infectious mosquitoes. This is not so difficult as it may at first appear, if we consider what are the habits of mosquitoes. Mosquitoes rarely travel so great a distance as half a mile and they become infected chiefly by biting native children. Consequently, if the native villages are not allowed to encroach within half a mile of a European camp such mosquitoes as it contains are not likely to become infected. Since, moreover, mosquitoes are not likely to bite by day unless they are too young to be infectious, it is possible by only paying the visits to the native villages which may be necessary, by day, and avoiding them at night very greatly to reduce the chances of being infected. Though among natives it is mainly young children who infect the mosquitoes, and a European may direct the work of

adults night after night without running much risk, a white man who has got the malaria parasites into his system is just as great a danger as a native child, and should be most careful in the use of his mosquito-net out of consideration for his neighbors. A man who is suffering from yellow fever may, if he likes, discard his net after three days, but it is very difficult to say when a man who has had malaria ceases to be infectious to mosquitoes. Needless to say, it is absolutely essential that every ward of a hospital in the tropics should be made mosquito-proof, and that where it is known that infected mosquitoes are in possession of a room, they should be exterminated by fumigation.

Having mentioned mosquito-nets, it will be as well to add one or two practical hints relating to them. Anyone who has lain under one and watched his enemy outside, working up and down, carefully trying every mesh, will know that a single small rent in a net will make it almost useless; while a net which is not carefully tucked in all around the mattress, but allowed to hang down in loose folds, will merely serve to gather in mosquitoes which have spent the hours of daylight under the bed. Where much dependence has to be placed on a mosquito-net it is important to remember the conditions under which mosquitoes prefer to take wing and to keep the house well lighted and well ventilated.

Conclusion

I hope that this short review of the habits of mosquitoes may be of some use in making clear the reasons why they constitute a danger to man, and, in outlining the methods to be employed against them, I would like, however, to add by way of conclusion, a few words of caution. Important as the mosquito undoubtedly is, it must not be exalted at the expense of other matters of equal importance. It should not, for instance, be forgotten that, while anti-mosquito measures are so difficult, costly, and often, unfortunately, only partly successful, we have in quinine a weapon which can be used directly against malaria itself. I might have said, when I spoke of avoiding the bites of infectious mosquitoes, that one method of doing so is to remove the mosquitoes' source of infection by dosing the whole local population with quinine. There are places where this has seemed the only way of fighting malaria and has produced excellent results. Certainly those who, from a study of the mosquitoes' habits, recognize that they cannot altogether escape the danger of being bitten by them, may well be glad that they have the simple defence against malaria that is provided by the daily quinine.

We have learned a great deal from the work of the men who first studied the anopheles mosquito and malaria. It has revealed the fact that a large number of diseases are due to vegetable parasites, which can be transplanted directly from one person to another, but to animal parasites which, as they must pass through alternating phases of their development in different animals, cannot be transmitted directly from man to man.

The work upon malaria has been so splendidly done, and its practical applications are of such immediate importance that the great principle which it has revealed is apt to be overlooked. It would be little short of a disaster if the first discoveries of the pioneers made us forget, even for a while, that in those climates which are peculiarly suited to the lower forms of life, malaria is not the only disease nor mosquitoes the only insects to be feared. Already we know that anophelines are not the only criminals in their family, but that several species of mosquitoes are concerned in disseminating different diseases; that the tse-tse fly carries the fatal sleeping sickness and perhaps other disorders, too; that various ticks transmit disease, among them, relapsing fever; that while bugs are under suspicion on several counts, fleas are known to be active agents in spreading plague; that the common housefly so often has contaminated feet that by some it is called the 'typhoid fly'; that, in places, the soil abounds in minute worms which will burrow through the sole of a bare foot, and, having thus gained entrance to the system, take up their abode in the intestines and give rise to an exhausting and sometimes fatal anemia. Yet this is only the beginning of a list which will, without doubt, be greatly extended within the next few years. In fact the days may be coming when we shall recall with a smile the exclusive interest we once felt in the mosquito. The memory of the early work may indeed be needed soon to remind us that increased knowledge does not multiply the number of diseases, but, by bringing our enemies into the open, adds to our power of resisting them.

Mining Laws of Peru

The unit of the mining claim is the pertenencia of 100 by 200 metres, being 2 hectares, or 4.94 acres, in the form of a prismoidal solid of infinite depth. In placers, coal, and petroleum deposits the pertenencia is 200 by 200 metres, or 9.88 acres. A concession may embrace up to 60 pertenencias. Prospecting and exploration concessions are granted, in size from 60 to 600 pertenencias, but one person or company may obtain several such concessions. These are granted for one year, but may be extended for another year. A small tax of 2s. per hectare per year is paid on prospecting grants. Mining concessions pay £3 per pertenencia per year, payable semi-annually. Nonpayment during three half-years cancels the title, but arrears may be paid before that time with 20% fine for the part a half-year overdue, and 40% for that a year overdue.

Any Peruvian citizen or foreigner capable of owning property in the Republic may acquire mining property, except certain officials having to do with the issue of titles or local administration, and except employees, who cannot denounce mines within 10 kilometres of the nearest point to their employers' property. The right exists of expropriation of surface area for necessary buildings and shafts. Persons interested will naturally secure a copy of the mining laws, which are published in Spanish and in English, the latter being a translation by Fernando C. Fuchs, engineer, a member of the mining board and of the faculty of the School of Mines.—*West Coast Leader.*

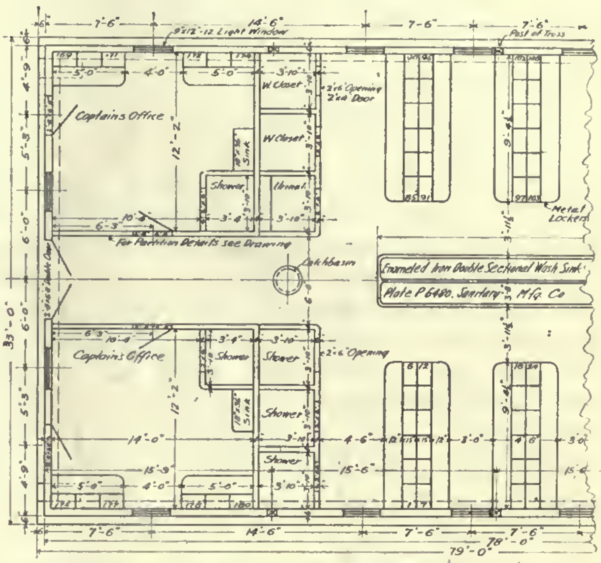
A Concrete Wash-Stand

By Frank A. Bowman

The design for a concrete wash-stand shown in the accompanying illustrations is novel and may be of interest. The idea was to make something cheap, serviceable, and of neat appearance. The stand was never constructed, because it was thought that the class of labor available would be unable to make a good job and that the cement would be apt to chip off, and also become discolored and unsightly from the iron ore.

The specifications called for 'Medusa' white cement and an approved waterproofing material incorporated with it, the cement to be troweled smooth. Hot and cold water lines are provided under the trough, with suitable connections to pass up through the sleeves, terminating in a double faucet so as to have a hot and cold water faucet in each half at intervals of about 8 ft. The miners use individual wash basins, which they keep in their lockers. While the design was not constructed, I believe it might be used successfully under other circumstances, and submit it for what it is worth.

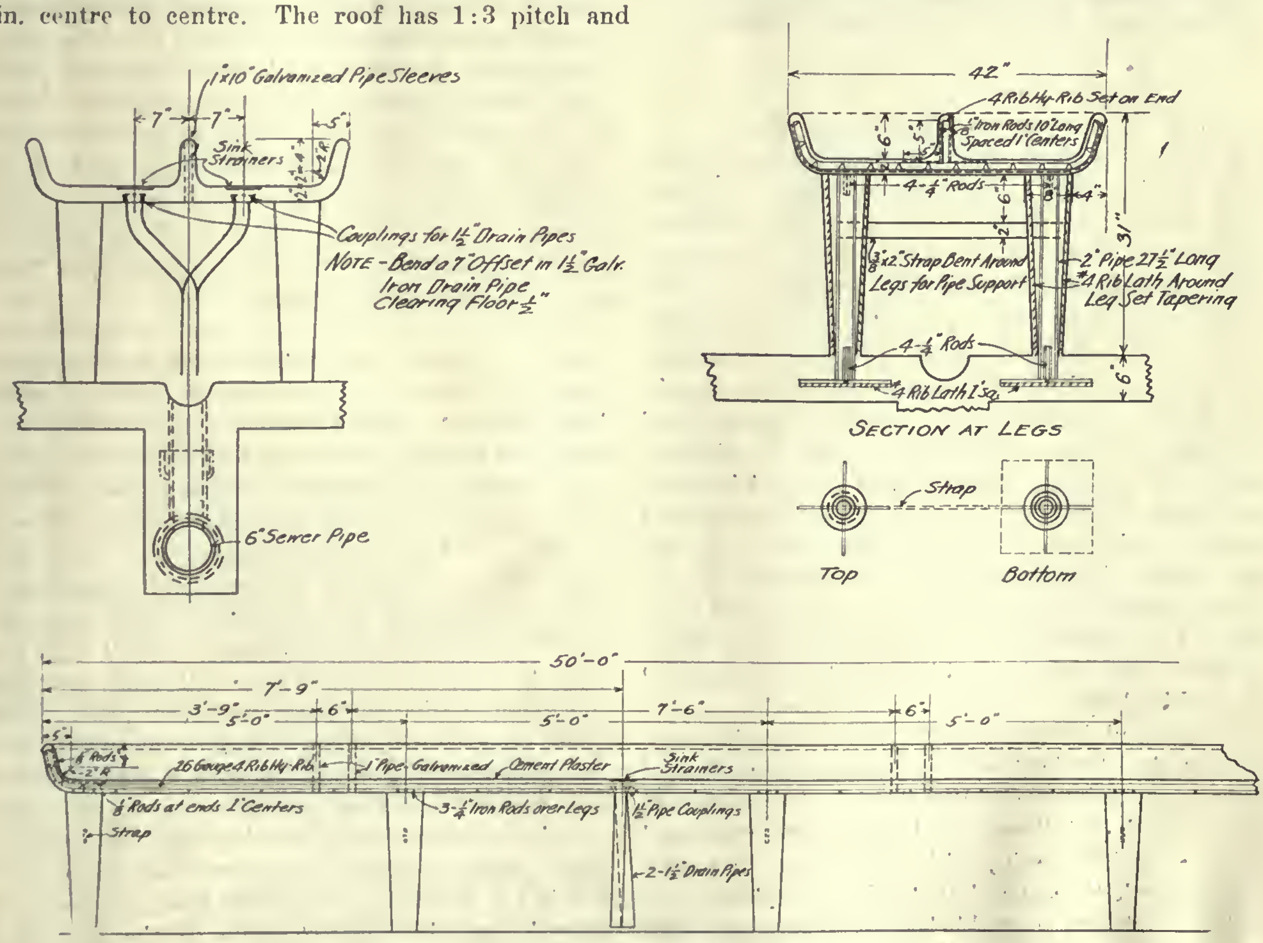
The floor plan of the 'dry' or change-house in which the concrete wash-stand was to have been used shows the general arrangement of the lockers and also shows the type of wash-stand that was chosen. It was built in two sections 24 ft. long, with a 3-ft. aisle between the water pipes, which passed overhead from one sink to the next. The 'dry'-house can accommodate 168 miners. It is 32 by 78 ft., with 2 by 6-in. by 10-ft. studs placed 16 in. centre to centre. The roof has 1:3 pitch and is covered with National asphalt-gravel surfaced roofing. It is supported by four Fink trusses and 2 by 10-in. purlins, and the building is sheathed all



PLAN OF CHANGE HOUSE.

over with No. 4 shiplap. The sides and ends are covered with 26-gauge galvanized corrugated iron. The floor is of concrete 4 in. thick, with a 2-in. finishing coat which extends over the rubble foundation to the outside. The sills are bolted to the foundation, which is 18 in. thick. No. 2 rib-lath is used on the walls, and the ceilings are lathed to the gables with No. 4 rib-lath. Cement plaster is used with some hair and lime paste in the first coat.

The only piping under the floor is the drain pipe.



LONGITUDINAL AND CROSS-SECTIONS OF CONCRETE WASHSTAND.

which is arranged so that any obstructions can be removed. The floor slopes to the centre ⅛ in. per foot, and the openings to the drain are covered with cast-iron gratings to prevent any large pieces of refuse from getting into the drain to clog it up while washing down the floor with the hose. The heating and water pipes enter the building from an underground trench and pass along the walls on the east side of the building. The hot and cold water pipes pass overhead and down to the sink. The Van Auken vacuum heating system is used. Rococo wall radiators are used under the radiators and on the end walls. Three 18-in. crown ventilators with dampers are set in the gables. The partitions are 2 in. thick, of cement plaster on hy-rib set vertically, and exposed corners are protected with metal corner beads. This design presents several features which are an improvement over present practice on the Mesaba range, particularly with reference to cost and serviceability.

Standard Screens for Sizing Analyses

By R. H. Richards

Great interest has been shown in recent years, and rightly so, in the importance of having standard sizes of screens, or sieves, in laboratories where sampling and screen sizing has to be done. The need of such standard is occasioned by the fact that without it the worker on mill or furnace products in one part of the country cannot read articles written by workers in another part of the country, and translate the figures obtained into the measures to which he is accustomed in making his own experiments, unless he knows the sizes of grain that are dealt with in the experiments described.

Efforts have been made in this direction from time to time, and I will refer to two. The sieve scale adopted by Rittinger, in his classic work on ore dressing, began with 1 mm. and the sizes for the screen holes above 1 mm. were obtained by multiplying each lower size by 1.414, or $\sqrt{2}$, in order to obtain the size next larger, going up in this way until he reached 64 mm., about 2½ in., the largest size that, in all probability, would be needed, and similarly obtaining sizes below 1 mm. by dividing the size of the hole in each screen by 1.414 in order to obtain the size of the hole in the screen next smaller, and so on down the series until the smallest possible size of screen hole was reached. So far as we know, Rittinger simply worked out this sieve scale as a desirable plan, but apparently no manufacturer took up the making of the screens, and no standard set of screens was to be had.

The second instance to which reference is necessary is the standard set of sizing screens adopted by a commission appointed by the Institution of Mining and Metallurgy, of London, and presented at its twentieth session, 1910 and 1911. This commission took the ground that miners, millmen, and metallurgists are so wedded to the use of the word 'mesh' as descriptive of the size of a sieve that it was unwise to try to introduce any other mode of designation. It is known to all who have given any thought at all to the matter, that the word mesh does not define the size of the sieve hole, and therefore the size of the product which the sieve makes. For example, I have before me the catalogue of a prominent manufacturer of screens in which it is stated that a 1-mesh screen with the coarsest wire that is used by this company would have a hole 0.030-in. diam., while the 14-mesh screen with the finest wire would have a hole 0.061-in. diam. There are sieves made by this manufacturer that have 14 different sizes of wire, ranging between these two extremes. The 14-mesh sieve therefore has 16 different sizes of hole, according to the 16 different sizes of wire used. Therefore the writer who speaks of a 14-mesh sieve in his descriptive article may mean to his reader that he is talking about grains anywhere from 0.030 in. to 0.061 in., failing utterly to convey an accurate concept to another experimenter.

The Institution commission, in making its screen set, known as the I. M. M. standard screens, fully realized this difficulty and met it by arranging to use wires of the same diameter as the width of the holes. This gives definite information as to the size of the grain that is meant when a given mesh of the sieve is used. These screens, however, do not have a constant ratio between two consecutive sizes: in fact, the ratio between the width of 100-mesh holes and 90-mesh holes is 1.095, while the ratio between 30-mesh and 20-mesh is 1.508. Other lesser variations occur all through the series, and there is in fact no attempt at a uniform ratio. There is another difficulty which this method develops, since in order to have screens of uniform size of opening, double-crimped wire cloth must be used. A prominent manufacturer of screens informs me that it is quite difficult to make double-crimped wire cloth where the wire is as large as the size of the holes, particularly when one gets to the coarser sizes, and if single-crimped wire cloth is used the wires are not fixed and the sizes of holes vary to a fatal extent by the slipping of the wires.

I believe there are strong reasons in favor of using a constant ratio between the apertures in a consecutive series. In making a series of sizing tests from a crushing machine it is necessary to know the proportional amount of the sizes at different points down the series, so that a curve may be drawn. If one pair of sieves has a small ratio of aperture of holes, and another has a very large ratio, then no regular statement of quantities of products made by the oversize of the successive sieves will give its full meaning, nor will it be possible to make a curve which will truly represent the result of that crushing operation. Also, if the series of products obtained are to be subjected to any concentrating operation with a view to ascertain the possibility of concentrating the ore, there will be no fair comparison between two products where in one instance the coarsest grain in the product is 1.5 times the size of the finest, while in the second case the coarsest grain in the product is only 1.09 times the size of the finest grain. The

results of concentrating two products differing so completely in their limits of size as this would fail entirely of being comparable one with the other. Again, the very fact of using 'mesh' as the standard of size of sieve invites the man who has not obtained the I. M. M. standard sieves to talk about his products by use of the word mesh, when his products are made by sieves of different make and therefore have different sizes of holes from the I. M. M. standard screens.

For these three reasons: (1) the difficulty of making double-crimped wire cloth of such coarse wire, (2) the difficulty of drawing deductions from curves and of comparing results, and (3) the difficulty of others not provided with the I. M. M. standard using the word mesh, it seems to me that a standard set of screens, standardized according to the size of the aperture instead of according to the number of meshes, having a constant ratio throughout—for example, Rittinger's ratio of 1.414 or $\sqrt{2}$—and using wires that are smaller than the aperture, thus permitting the use of the most suitable kind of double-crimped wire cloth, cannot fail to have great advantages over any series of standard screens based upon mesh.

Such a set of standard screens has recently been prepared by the W. S. Tyler Co. of Cleveland, Ohio. This set of screens begins with a 200-mesh screen that has been standardized at Washington by the United States Bureau of Standards officials, and uses the ratio 1.414 from 200-mesh to the maximum size. Since the ratio between the apertures of two consecutive screens is always the same, a sizing test made with these screens will show the proportional quantity of material according to a perfectly definite law. That is to say, the largest grain in any product will always be 1.414 times the size of the smallest grain in that product. As a consequence of this, the series of products obtained can be plotted as curves which truly represent the quantities according to a definite law. If concentrating tests are desired upon these products, the results of concentrating will be comparable throughout the series of products, ranging from the coarsest to the finest.

I warmly commend this effort to make a standard set of screens for use in sizing tests. I hope that they will generally be adopted by mining engineers, mill men, and metallurgists in order that papers written on ore dressing topics may possess the uniformity in the description of the products described.

Elevating tailing at the Calumet & Hecla mills is done by wheels of the following dimensions:

	No. 1.	No. 2.
Diameter of wheel..	62 ft. 6¾ in.	51 ft. 4¼ in.
Width of wheel.....	11 ft. 9 in.	11 ft.

Development Work in Colombia

By An Occasional Contributor

A property is under development about 45 miles above Quibdo, Colombia, on the Audagadua river, a branch of the Atrato, which flows into the Gulf of Darien, over 600 miles from Cartagena and about the same distance from Colon. The gravel deposit is a pre-volcanic river channel about 30 ft. below the present normal river level, with an overburden of tough volcanic blue clay and big boulders, thus requiring good timbering. This material is locally called *agomassa*, the bedrock is decomposed diorite, and width of the pay-gravel is from 50 to 60 yd. Its depth is about 2 yd., the gold content is satisfactory, and $1 per cubic yard will cover the cost of mining and washing.

The altitude at the river level is 650 ft. The surrounding country is rough, broken, and precipitous, densely covered with a tropical growth, making cheap timber of a good quality for all mining purposes available at a very low cost. Every side canyon supplies abundant water for all purposes, which can be cheaply developed by short ditch-lines, the outer shells of the 'Balsa' palm trees supplying flumes when necessary. The palms also supply the boards for floors and siding for bungalows, of which the roofs are thatched with leaves.

ALONG THE MAGDALENA RIVER, COLOMBIA.

Labor of fair efficiency costs from 80c. to $1.20 silver, the exchange being at the rate of $2.25 or $2.50; this includes board, bringing the total cost of labor to 60 or 75c. gold per day. At present the employees are all negroes, but later it is planned to bring in white natives from Antioquia. As a rule these men are tractable, honest, and as willing to work as a tropical climate permits. They are all expert canoemen, and the freight cost from Quibdo to camp is less than it would be by big teams in the mining regions of California, Nevada, or Arizona for the same distance. The laws in this district do not permit foreigners to denounce or locate mining claims, hence it is no proper region for prospectors, for to secure holdings it is necessary to either buy or lease from native owners. They, contrary to some reports, are usually fair to deal with, leases being given on a 15 to 20% basis, which is reasonable if a proper selection is made.

So far as I have been able to judge, the titles here are just as safe and secure as a United States patent would be in America.

Foodstuffs naturally cost more here than at home, on account of duties and numerous reshipments, but on the whole the low labor cost more than counterbalances this increase. All mining machinery and supplies are allowed virtually free entry, only a nominal charge for office fees being made, as in Mexico. The climatic conditions are such that it requires from six months to a year for a Northerner to become acclimated. The nights are cool and, almost without exception, rainy, the precipitation averaging for the past six months at the rate of 300 inches per year. October, November, and December constitute the winter months; the other nine months are hot. As it requires considerable time and expense to 'get a line' on conditions here, it would prove a losing game for anyone to come into this region unless satisfied to put up with the conditions obtaining and financial backing to the extent of $20,000. With those prerequisites, if the prospector can stand the climate and knows the game he will succeed.

A. I. M. E. Meeting

The annual meeting of the American Institute of Mining Engineers was held in New York City, beginning February 17 and continuing until February 20. The sessions were held in the Engineering Societies building, 29 West 39th street, which also served as headquarters. The arrangements for the meeting, aside from the technical sessions, were made by a committee consisting of G. F. Kunz, E. Gybbon Spilsbury, L. D. Huntoon, Thomas Robins, and H. J. Seaman. The meeting was opened Monday evening by an informal smoker in the Institute rooms. On Tuesday morning the annual business meeting was held. In accordance with previous announcements, the regular order of business was suspended, and the proposed new constitution was first voted upon. This was adopted with only six dissenting votes, with the exception of the provision for creating a class of fellows, which was defeated. The amendments proposed by C. R. Corning and G. C. Stone were also carried by a substantial majority. The letter ballots for officers for the ensuing year were canvassed, as provided in the newly adopted constitution, and the following were elected: President, Charles F. Rand; past presidents; Charles Kirchhoff, James F. Kemp; vice-presidents, Karl Eilers, Waldemar Lindgren, B. B. Thayer, S. J. Jennings, T. H. Leggett, F. W. Denton; directors, W. J. Oleott, C. S. Robinson, E. L. Young, J. A. Holmes, John H. Janeway, Jr., J. W. Finch, J. W. Richards, E. P. Mathewson, L. D. Ricketts; to fill the unexpired terms of C. F. Rand and J. F. Kemp: R. W. Hunt, James Gayley.

In the afternoon, following luncheon at the Engineering Societies building, a technical session was held, and papers on mining and geology were read and discussed. In the evening F. H. Newell, Director of the U. S. Reclamation Service, gave an illustrated address on irrigation. In accordance with the program, all day Wednesday, February 19, was devoted to papers on iron and steel. Unusual efforts had been made to secure a wide variety of papers and to stimulate thoughtful discussion. The committee having it in charge have made this preliminary announcement concerning the papers available:

J. R. Finlay, 'Valuation of Iron Mines.' About 100 men who are well informed on this subject (or on phases of this subject) have been selected in advance by Messrs. Finlay, Birkinbine, and others and have been invited by the Committee to study the paper and send in advance discussions, or to discuss it in person. So much interest has been evoked by Mr. Finlay's valuation of the Lake Superior mines that an interesting debate on this subject is expected.

Albert Sauveur, 'Notes on Cast Iron.' Several men selected by Messrs. Sauveur, J. E. Johnson, Jr., and others have been invited to study this paper in advance and prepare discussion for the meeting.

Robert W. Hunt, 'Comparative Notes on Steel Rail Rolling.' Requests are also being sent out for discussions on this paper, which will no doubt attract many to attend.

H. F. Miller, Jr., 'New Design of Open-Hearth Furnace Using Producer Gas.'

Henry M. Howe, 'Why Does Lag Increase with the Temperature from which Cooling Starts?'

B. G. Klugh, 'Microstructure of Sintered Material.'

F. Louis Grammer, 'Blast-Furnace Slag Analyses for Twenty-four Hours.'

H. F. Miller, Jr., 'Methods of Preparing Open-Hearth Steel for Castings.' This paper was received at the Cleveland meeting too late to be discussed, and, as it has aroused a great deal of interest, it will be brought up for discussion at this meeting in response to requests.

In addition to these papers and discussions, the Committee will make one of the chief features of the day a symposium on the subject of sound steel ingots. The following papers dealing with this subject are on hand and will be in print for the meeting:

B. Talbot, 'The Production of Solid Steel Ingots.' with extensive discussion which has already been contributed.

P. H. Dudley, 'Piping and Segregation of Ingots of Steel and Ductility Tests for Open-Hearth Steel Rails.'

E. A. Beck, 'The Use of Anti-Piping Thermit in Casting Steel Ingots.' These three papers describe new processes for making sound ingots. In addition to them, two other processes which are now being tested commercially, but have never before been publicly announced, will be described if the experiments upon them can be brought far enough along to warrant the report, which at the present time seems probable.

Following these papers a general discussion of the subject of sound steel ingots, on behalf of both producers and consumers of steel, will be had, presented under the following topics:

1. Is the present method of getting rid of the

pipe by cropping, a safe and reliable device for making sound steel?

2. Is it desirable to increase the amount of metal arbitrarily cropped off the top of an ingot, and, if so, what would be a fair excess price to pay for cropping off 20 per cent?

3. Is it commercially practicable to make ingots without pipes or blowholes, and what additional expense of manufacture would be justified to accomplish this result?

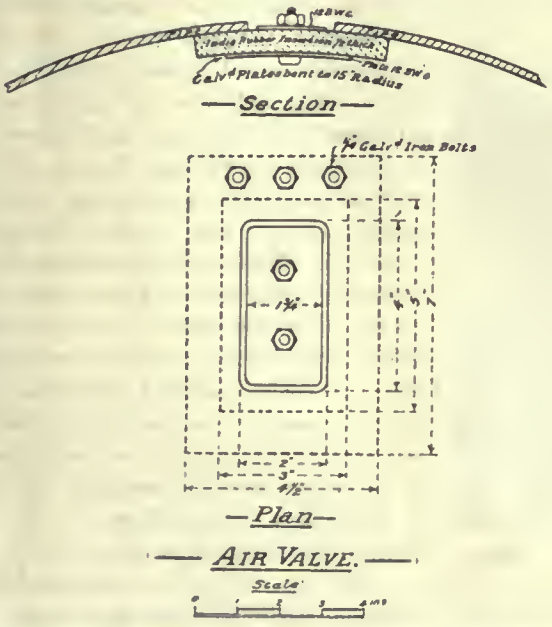
4. What process for making pipeless ingots seems the most promising of commercial success, and why?

The discussion will be opened by engineers whose names are already prominent in this connection, and a large number of engineers for railroads and other consumers, steel-makers, and metallurgists. Non-members of the Institute have been invited to attend and enter the debate in order that all sides of this question, which is probably the most important now before the steel public, may be adequately represented.

Provision was made for a technical session on Thursday, if it should prove necessary. The care shown in preparing for the meeting at Cleveland produced such admirable results that it is to be hoped that this practice will characterize all future meetings of the Institute.

Air Valve for Water Pipes

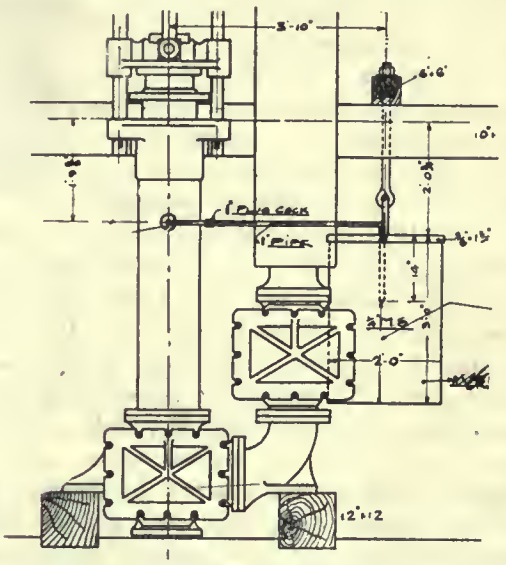
Collapse of high-pressure water pipes by creation of a vacuum through the sudden emptying of the pipe, may be avoided by fitting an air valve similar to the accompanying cut, which was used in a new



30-in. pipe in New Zealand for hydraulic purposes. It is simply a flap, hinged on one end to the inside of a pipe, just below the penstock, and is kept closed by pressure of the water; but immediately the pipe is suddenly emptied by accident or otherwise, the valve opens, and allows air to rush in. In 1898 a 30-in. steel pipe at Waikino, New Zealand, was partly destroyed by a landslide, the pipe emptied, and as there was no air valve, the whole length down the hillside collapsed, due to a vacuum in the pipe. The next pipe had a valve fitted.

Plunger Pump Regulator

Plunger pumps elevating mill pulp often give trouble through emptying the sump, and then refuse to pick up their load again, when the sump fills up. This is overcome at several mills in Kalgoorlie by means of a self-priming apparatus. The duplex Cornish pump at the Yuanmi mill, East Murchison goldfield, of Western Australia, with plungers 10 by 48 in., lifts pulp from the stamps to a diaphragm-cone, and also from the tube-mill and grinding pan. The pump is provided with a regulating bucket. The object of this gear is to constantly keep the pulp within an inch or so of the bottom of the suction pipe, which is done in the following manner: The regulating bucket, 2 by 3 ft., is filled with water. A 1-in. pipe is connected with the pump barrel, as close to the stuffing-box



PUMP WITH REGULATING BUCKET.

as possible, and is led to the regulating bucket. On the up-stroke of the plunger pulp is drawn up the pump suction pipe, and also from the regulating bucket. On the down-stroke the pulp is forced through the pump delivery column and also into the regulating bucket; only a small quantity surges to and fro between the pump-barrel and the regulating bucket. When the pump is on the point of forking, the amount of pulp necessary to prevent it from doing so is drawn from the regulating bucket, and is returned on the down-stroke. A cock may be fitted to the pipe leading from the pump-barrel to the regulating bucket, so as to adjust the quantity of pulp surging to and fro. The advantages of this balancing method are: that the pump being always nearly in fork, the sump is practically empty; no intermittent choking with sand occurs; the delivery through the rising column is constant; and the pump pit then provides the necessary storage for drainage from the stamps and grinding or other plant, when the mill is stopped for any purpose. There is, of course, a slight loss in the volumetric efficiency of the pump; but, on the other hand, a higher plunger speed can be adopted, since the use of the regulating bucket eliminates air-lock shocks. The loss of power caused by the surging of the pulp from barrel to regulating bucket is small.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

The Institute and Western Members

The Editor:

Sir—In view of the diverse opinions which have been held by members as to the affairs of the American Institute of Mining Engineers, and somewhat in answer to James Douglas' statement in the *Mining and Scientific Press*, January 25, 1913, I think I voice the opinion and sentiment of the majority of the members in this section when I state that at all times they have had the good of the Institute at heart, however much they may have differed as to details; that they have deplored conditions which may have reflected on the Institute itself or any of its members. But that there has ever been a thought of withdrawing, as individuals or *en masse*, from the Institute, by members in this region, is wholly without foundation, and I believe this applies to the whole Western membership.

Personally, I hail with satisfaction the apparent approaching settlement of all internal troubles, and in this sentiment I am sure I am joined by the greater number of Western members. It is my opinion that the Institute transcends in importance to the members, the individual, however great the influence may be, and anything which tends to disorganization must be frowned upon. And while Western members may reserve the right of preference and always will, they may always be found ready to promote the best interests of the Institute and to accept whatever decision the majority may arrive at. Let us all remember the past only for the value which we have had from it and let us be determined to make the influence of the Institute continue to grow wherever mining, metallurgy, and allied science is carried on.

L. K. ARMSTRONG.

Spokane, Washington, February 1.

The Benguet District

The Editor:

Sir—The articles written by Arthur W. Geiger on the above-named district for the *Mining and Scientific Press*, while interesting and in the main correct, do not throw sufficient light on the past of the district to enable readers not familiar with its history and conditions to make a just estimate of what has been done, and what the possibilities may be. His observations and impressions are evidently those of a visiting engineer, or of one new to that country. I hope, therefore, that he will pardon me if my impressions differ somewhat from his, for mine were gained during a five years' continuous residence, in charge of one of the properties to which he gives honorable mention, the Benguet Consolidated, or more properly the Minnesota mine, as all the productive work was done on that claim. When I took charge in 1905 this was merely a prospect, with 220 ft. of adit, all on the same level. During my time there it was equipped with a small stamp-mill and the first cyanide plant erected in the Islands, and was developed for a thousand feet in length by a width of nearly 100 ft. on three levels, the lowest being 15 ft. below normal water-level.

It might easily be inferred from Mr. Geiger's remarks concerning the general grade of ore in the district that ore of really good grade, and of workable width, does not exist. On this property, however, a number of shoots of ore, several hundred feet in length along the lead, and from 1 to 5 ft. in width, beginning thin at ends and being thickest at middle, assaying well above $20, were developed on two levels. Two of these were in a zone near the foot-wall, and one in a zone near the hanging wall. The ore in the former was soft and characterized where rich by a black iron sulphide which, when ground very fine, would yield its gold by amalgamation. The ore in the hanging wall side of the lead was of an entirely different character, being hard compact quartz, in fragments, and cemented by a dark bluish quartz matrix, evidently deposited from hot alkaline solution. The gold was in finely disseminated particles of bright iron sulphide, mostly in the matrix, but not limited to it. A great deal of iron sulphide carrying little of value existed in the mass of the lead matter outside of the pay-shoots, this sulphide being in distinct but not large crystals of a dull bluish color. A shipment of not particularly clean concentrate made to the Selby smelter returned over $100 in gold per ton. Samples panned from the pulp as it left the end of the plates would assay about $150 per ton, and similar samples panned from the leached charges before a table was installed would yield about $30. After table work was begun, experiments were made by fine grinding concentrate in a miniature tube-mill improvised from an old acid jar, which, with 8 to 12 hours grinding with cyanide solution of 8 lb. per ton, yielded 90 to 95% in solution. Dee W. Minier, who was assayer and engineer on the property at the time, made these experiments. It is possible that I have forgotten the exact figures and that he can give more exact ones. If I am in error, I should like him to set me aright. My impression is that KCN loss was about 4 lb. per ton. At any rate, the work proved that with fine grinding most of the gold was liberated in such form as to be amenable to cyanide, and the indicated treatment was to grind fine the concentrate at least, or better, to tube-mill the entire sand product, since this, as separated from the slime after amalgamation, would assay from $10 to $16. The sand with the concentrate removed would assay from $5 to $8 and yield not to exceed 70% extraction with three weeks leaching cycle. The slime treated separately assayed several dollars per ton higher than the sand product, so the obvious treatment was to crush in stamps, as was already being done, amalgamate the coarse gold (25 to 35%), and tube-mill the sand product, combine with slime produced in crushing, and handle the combined product in a filtration plant. Leach-

ing has no place in treating ore of this character and grade. Had the company had sufficient capital, it would have paid to have discarded the old combination plant and to have built a small but efficient all-sliming plant. In view of the facts, the loss of the old plant need not have been a serious matter—indeed, it might have been a blessing in disguise, had the owners been in a position to rebuild properly.

ANTIMOK CANYON AND THE FIRST CYANIDE PLANT IN THE PHILIPPINES.

The Bua mill, situated just below the Consolidated, was much better adapted to the ore it had to treat, for this was of entirely different character from that of the Consolidated. It came from a different vein system and consisted mainly of calcite-manganese vein material with little quartz, some sulphide, and much of the gold free on the cleavage planes of the calcite and rhodochrosite. Better results were obtained on the plates, and the sand yielded the gold up to 80% by leaching, while the slime was sufficiently low to allow of its being run to waste without serious loss. The ore, moreover, was alkaline as it came from the mine. That of the Consolidated was distinctly acid. The two ores together would have made a fine working combination, handling each separately through amalgamation, then leaching the Bua sand and combining the slime with the whole ground product from the Consolidated for agitation and filtration.

If Mr. Geiger has included these two mills in his count of seven, he should say that there *have been* seven, for these two are certainly in the 'has been' class. Yet they yielded considerable gold during their brief careers. I am not in a position to say how much was produced from Bua, but during the time I had charge of the Consolidated over $140,000 was shipped. Considerable more was produced subsequent to the loss of the cyanide plant by working up old dump stuff and low-grade surface material together with some ore from the mine. I am unable to state the amount of this production, which was all from amalgamation, and certainly did not represent over 50%, at the most, of the included gold. Since the typhoon of October 1911, which removed everything but the crusher and stamps, I understand there has been no production.

To one coming to that country now, it no doubt appears that it was a foolish procedure to place mills in such a position as that which the Benguet Con. occupied. In explanation, it should be remembered that conditions were different in 1905. The stream was running in a well defined channel, ample to carry all flood-water, and had cut to bedrock. The bank was of hard cemented gravel covered with vegetation, and offered no evidence that the water had been over it in a century. The surrounding hills, which Mr. Geiger describes as being scarred by great slides, were then covered with vegetation, and such old slides as showed were solid and grass covered. We had no difficulty in diverting the water for power purposes, nor in conveying it to the mill, gaining a head of 125 ft. in a little over 3000. Still the wheel was set 24 ft. above the normal water-level in the stream opposite the mill. The millsite was chosen because of easy water-line to it, proximity to ore supply, and topography generally suited to the class of mill being built. It served the purpose well for several years, but an unusually heavy typhoon in the fall of 1908 raised the river to such an extent that it cut under the slime-tanks. Prompt action saved them, and the following summer the channel was straightened and a protecting wall built. When the big storm of October 1909 came, accompanied in its midst by a distinct earthquake, great slides were thrown down into the stream, the flood backed up, broke these dams, and the mass of water, boulders, and trees, coming down with great velocity, made short work of everything within its reach. Indeed, it not only removed the greater part of the Consolidated mill within a few minutes, but tore away the site as

BENGUET CONSOLIDATED MILL. GRASS ROOF LATER REPLACED BY IRON.

well. After this storm the river level was fully 25 ft. above its former level for about two miles. In time this accumulation will gradually be removed by successive floods, but so far little impression has been made on it. Each year new slides occur, the country having been so badly shaken by the earthquake. It also makes it difficult to divert water from the streams, as what is water-level this year may be ten feet above or below next. It may be possible, as Mr. Geiger suggests, to develop hydro-electric power on the larger streams, notably the Agno river, but take my word for it, no one who wishes to retain a dam through a rainy season should put it in one of those streams whose drop is hundreds of feet to the mile, and which in flood times will carry down-stream boulders weighing tons, at a high velocity. No dam could withstand the shock. We never attempted to dam the Antimok (though on various and several occasions we did *damn* it, but apparently to no purpose). If I were figuring on operating there again, I should use oil-engines, unless electrical power were available by purchase.

Referring to evidences of earlier workings, we found on the foot-wall side of the lead at Antimok well preserved tunnel sets, made from the pitch-pine wood of the country, in a remarkably good state of preservation. The sets consisted of the usual four pieces, but the posts had tenons on each end, fitting mortises in both sill and cap. The height in the clear was about 3 ft. 6 in., and the width about 3 ft. Lagging had been used, though most of it was gone. The Igorrotes say that years ago Chinese worked here, and that within the memory of some of them, fragments of Chinese pottery were in evidence at the camp, where the ore was evidently ground in the many stone mortars still present. I do not believe that quicksilver was used. The gold was probably recovered by extremely fine grinding and panning, which is the method still used by the Igorrotes. The ancient workings extended along the outcrop of the foot-wall zone of ore fully 500 ft. up the slope and for a distance of 100 ft. below the outcrop, the stopes being filled, or having become filled naturally, by material from the sides. We opened up the whole extent of these workings by raises through the ore, and removed and milled the most of the filling. This assayed from $6 to $10 per ton in gold. Some remains of old timber were found in the filling, but not many. It is probable that stulls were used temporarily. The width of filling mined was from two to seven or eight feet, though of course this did not necessarily represent the original width of ore. The limitation of about 100 ft. in depth seemed not to be on account of lack of ore beyond, for the good ore was found to come right up into the bottom of the stopes, but to inability to mine further because of lack of air or some other difficulty.

Speaking of the ability of Igorrotes as packers, I once gave a contract to a young Igorrote to get 11 tons of limestone from the Comote mine to the Consolidated, a distance of 1½ miles, over one of the roughest pack-trails I have seen, for ₱10 per ton. He engaged his friends and relatives as packers (at the rate of ₱8 per ton), and they went at it, men, women, and children. They nearly worked themselves to death in the effort to get rich quick, and cleaned up the job within a few days, making four or five trips per day, with big loads. One woman brought in a load of 125 lb. and one man one of 187 lb. Our financier, who by the way had had the advantage of having been a *muchacho* to a Secretary to an American Commissioner for several years, went along with a light load, encouraging the others and doing the clerical work. While the above is not comparable with the feats of the Indian packers at the portages and in the Andes, it is, considering the size and weight of the Igorrote, not a bad record.

Prices of labor in the Benguet district must have advanced considerably of late, judging from Mr. Geiger's figures. It is possible that he includes the cost of 'chow,' which usually consists of a ration of rice and small dried fish, and costing formerly about 16c. Philippine currency. On the other hand, the price of dogs in the open market must have come down considerably, for, while I never personally purchased a dog for food purposes, I was under the impression that the price of a good *lean* dog, "on the hoof," was about ₱2.50. If the price has dropped to 50c., the Igorrote certainly has no complaint to make at the high cost of living.

Mr. Geiger falls into a quite natural error in speaking of the habit the Igorrote women have of playing what he terms a 'bow' as they walk along the trails with their loads. This is not a bow at all, but a section of bamboo with a portion cut out so as to form two long prongs like a tuning fork, and as they walk along they beat out a monotonous strain by striking this instrument on the forearm. The note varies according to the point along the prongs where it is struck. They play thus, not to ward away evil influence, but to while away the time. It is one of the few recreations the poor beasts of burden get.

I can heartily agree with Mr. Geiger in his statement that Baguio is beautifully situated. Nothing is more surprising to one going to that country with the expectation of seeing nothing but palms and tropical vegetation, to land at a modern health resort amid piney woods, with cool bracing air, and park-like surroundings. He is apt to doubt the evidences of his senses and conclude that he has wandered from his course and wound up in the Sierras of California—until he sees the people, and then he realizes that he is really in the land of the Igorrote, eater of dogs, erstwhile hunter of heads, but, withal, a right good fellow when you come to know him.

C. M. Eye.

Concheño, Mexico, January 1.

Rand mines in 1912 produced 25,506,361 tons of ore averaging $6.78 per ton. Working costs were $4.32 per ton, and the total profit was $60,854,400. Dividends paid amounted to $39,988,800. The totals to date are approximately 200,000,000 tons of ore, yielding $1,437,210,000, and $424,944,000 in dividends.

Special Correspondence

GLOBE, ARIZONA

WORK AT COPPER HILL.—SUPERIOR & BOSTON.—HOISTS AT THE INSPIRATION MINE.

At the Copper Hill shaft of the Arizona Commercial property, sinking is being continued below the 800-ft. level. Until the completion of the new concentrator of the Old Dominion in the early fall it is probable that all work in the Arizona Commercial will be confined to development. An interesting feature of the Copper Hill's shaft equipment is the cross-head now being used during sinking. The great danger of the possibility of the cross-head becoming caught in the shaft as the bucket is lowered and afterward falling upon the men in the bucket is obviated by the construction now being used. The cross-head is constructed as a platform and the men ride upon it instead of the bucket. Should it become hung up in the shaft, an improbable occurrence, because of the added weight of the men, its occupants would immediately signal to the engineer and stop the hoist. There are about 200 tons of high-grade copper ore

ARIZONA.

on the dump of the Idaho property, in the Dripping Springs district, awaiting shipment. The property is owned by J. P. Hayward and Lyman C. Woods. Assays from the property average 19% copper, $11 in gold, and 1½ oz. silver. The ore will be shipped to the El Paso smelter by way of Kelvin until the smelter at Hayden is ready to receive custom ores.

The Superior & Boston has over 75 ft. of workable ore in the raise that is now about 250 ft. above the southeast drift on the 800-ft. level. While the raise has been in ore from the beginning, it has been averaging as high as 9% copper for the last 70 ft. driven. The ore is copper glance and the average width of the shoot is about 7 ft., partly mined and partly revealed by drilling toward the hanging wall. It appears that the ore is dipping southeast from the raise, under Quo Vadis hill. This will necessitate driving in that direction on the 800 and 1000-ft. levels to explore the orebody beneath the hill. In the southeast drift on the 800-ft. level the showing is so encouraging that it is certain the 100-ft. level will be driven ahead very soon. The mine has been shipping excellent ore to the Old Dominion smelter at the rate of five carloads per week, and as soon as the raise has established connection between the 800 and 600-ft. levels the shipments can be increased to a carload per day. If the ore continues above the 600-ft. level the shipments can be still further increased to two carloads per day.

At the Iron Cap mine the shipments for January were considerably smaller than for the preceding month because of increased development on the 650-ft. level to explore the orebody farther to the east, and toward the Arizona Commercial end-line, the management having decided to drive No. 651 drift farther eastward before extending the stoping on that level. The chutes are being enlarged to a depth of 40 ft., which will allow larger shipments in future. At the Inspiration Consolidated Copper Co.'s property the installation of three 50-hp. Allis-Chalmers electric hoists is practically completed. The hoists are being placed at the Scorpion, Main West, and Incline shafts. The Incline shaft has been sunk 100 ft. below the 3450-ft. (sea-level) adit and will be sunk another 40 ft. to provide a sump. After completion of the sump a vertical 2-compartment raise will be lifted from the incline shaft at the top of the sump. The raise will be carried up to the 3450-ft. adit, where a 180-ton pocket will be cut. Waste from the pocket will be dropped through the vertical raise, and hoisted through the Incline shaft to Joe Bush adit, and thence trammed to the surface. In the incline adit, Mr. Flynn, the contractor, is placing a set of timbers daily.

PHILOMATH, OREGON

PLACER WORKING.—BIG NUGGETS.—GOLD KING.

There is still an abundance of rain and snow falling in Josephine county placer districts, and the hydraulic claims are enjoying the best season they have known for a number of years. Even the ground-sluice workings are busy; and while these employ such crude equipment as rockers, shovel conduits, and arrastres, they operate on rich ground, and give excellent returns. The Ruble placers, of Wolf Creek, are having a splendid run, operating two giants at the face and one at the grizzly. Both day and night shifts are employed. It was on this property that the Ruble grizzly, now used in placers all along the coast, had its beginning, S. C. Ruble being the inventor. It is a form of elevator used to remove tailing from ground that does not afford sufficient natural dump.

The Osgood placers, operating a battery of two giants in the rich diggings of Illinois river, near Waldo, are under the local management of John Logan. They are the property of F. H. Osgood, a prominent Seattle railroad and mining man. The mines were run a part of the season in conjunction with the old Logan & Simmons properties, but the latter have been closed down, and Mr. Logan will devote all his time to the Osgood. The Oscar creek placers, long noted for their production in big nuggets, are operating to full capacity, night and day. As with other Applegate river mines, the season has been an unusually good one, this stream remaining at a high stage for a much longer time than it generally does. The mines have already made several heavy shipments of gold to the mint, and a number of big nuggets have been uncovered. The record nugget from Oscar creek found several years ago was worth $500.

A crew of graders and brush cleaners is now at work on the right of way of the Pacific-Interior railroad, from Grant's Pass south, and contracts for the construction of the line have been let. Funds have been provided for the building and equipping the road as far as Hays Hill, and this much will be finished this year. It is now a certainty that the mines of Slate creek, Kerby, and Illinois rivers, as well as the copper mines of Waldo, will soon be favored with much-needed railway transportation. Assured of this, there is a decided activity in the development of all western and southern Josephine county mines.

The old Gold King mine, near Kerby, which attracted much attention five or six years ago, is soon to resume operations. M. Marks, who has been principal owner and general manager of the property from the beginning, spent the past two months on the property getting it in shape. While the Gold King has been idle, it was never abandoned. Mr. Marks has never lost faith in the mine, and his Seattle associates have remained with him. All are determined to

make the Gold King a paying property. J. C. Mattison states that the first shipment of machinery for the Oriole is expected soon from San Francisco. About 125 tons of equipment will come in the first lot, including a 10-stamp mill and water-power plant. The 10 stamps will be merely the first unit in the reduction plant, as the company confidently expects to increase it to 20 or 30 stamps within a year. The Oriole is now opened to a depth of 600 ft. On the lower levels, a big body of low-grade ore, assaying $9 to $10 per ton, has been uncovered, and this will be the principal milling ore.

BLACK HILLS, SOUTH DAKOTA

REPUBLIC DEVELOPMENT.—TITANIC LEASES.—FLATIRON MILL.

The Republic Mining Co. has been making some interesting ore disclosures in recent development work on its property in Blacktail gulch. The ore is a typical refractory silicious material, amenable to cyanidation. The company sank a new shaft and fortunately cut an ore-shoot in the quartzite at a depth of 100 ft. Since starting work on that level a considerable amount of work has been done in ore, exposing a liberal quantity. The company has ordered a pump and will dewater the Maggie shaft, in old workings in which milling ore is reputed to have been left from operations conducted about 12 years ago. It is probable that the company will erect a small cyanide mill the present summer.

The Titanic Mining Co., owner of 600 acres in the Carbonate district, has recently secured under bond a number of famous old mines, including the Iron Hill, Seabury-Calkins, and numerous others, giving a large area in a district that at one time produced handsomely, but which has not been worked in 25 years. The Titanic is preparing to sink a large working shaft 500 ft. west of the old Iron Hill shaft. The new shaft will be sunk to quartzite, which it is expected will be found at about 450 ft. Aside from being deeper than any previous working in the neighborhood, it will open virgin ground. Work will start soon, and as a preliminary bids have been invited for furnishing, delivered at the ground, sufficient square timber for 400 ft. of shaft. W. S. Elder, of Deadwood, is secretary. A new shaft-house is being erected at the Jungle mine, in the Custer Peak district, and everything put in readiness to commence shipping copper ore to the Galena smelter as soon as that plant is ready to receive it. Preliminary work and the making of ore contracts is being carried forward by the smelter people, and it is hoped to have the plant started at an early date.

The new mill of the Bismarck company, at Flatiron, will not be started until warmer weather, as it has been decided that since there is usually more or less trouble in starting up a new mill, there is no necessity for battling adverse weather conditions at the same time. The plant is patterned to a considerable extent after its neighbor, the Wasp No. 2, and will treat coarse crushed ore by leaching. The ore will be mined in open cuts, trammed 600 ft. to the mill, and dumped into bins of 475 tons capacity. From these bins it will be drawn to a No. 5-K Gates crusher. The product of this crusher will be carried on a 24-in. belt conveyor to two No. 3 Gates crushers, reduced to about ¾ in. and elevated to a 450-ton bin. Two sets of 36 by 15-in. Allis-Chalmers rolls and two shaking screens, set at an angle of 45° will insure a product that will pass a 3/16-in. square opening. This product will be drawn from a 475-ton bin to either of four conveyors and loaded into the leaching tanks. Of these, 5 are 28 by 9 ft. and one is 30 by 12 ft. Zinc shaving precipitation will be used. The plant is expected to have a capacity of 300 tons per day. The entire plant is driven by electricity, power being secured from the Consolidated Power & Light Company.

The annual report of the Homestake Employees' Aid Fund shows cash on hand at the end of the year, $23,338. Receipts during the year were: from employees (each man contributing $1 per month), $29,691; Homestake Mining Co., $12,000; interest, $402.20; disbursing checks uncalled for and credited back, $257. Disbursements were; death benefits, $15,200; injury benefits, $11,700.25; sick benefits, $6598; suicide benefits, $200. The balance in the treasury on December 31, 1911, was $14,686.31, so that during the year a gain of nearly $9000 was made. Of the death benefits paid only 3 were for accidents underground. The Supreme Court of the state has upheld the judgment of the lower court in the litigation between F. C. Crocker and the Cumberland Mining Co. Crocker sued for $15,000 back salary as general manager, and the company brought in counter claims, which resulted in their securing judgment against him in the sum of $5000. It is stated that the company will immediately be recognized and work resumed. The property is one of the richest in the Hill City district, and has produced high-grade free-milling ore. R. S. Jamison, president of the Imperial Mining Co., is being sued on his guarantee of the bonds of the Dakota company, of which about $72,000 are issued, and on which interest has been defaulted. Some years ago the Imperial company took over the property of the Dakota company, and a portion of the consideration was assumption by the Imperial of certain Dakota obligations. Mr. Jamison stated to have personally guaranteed the outstanding bonds of the Dakota, and is now being sued by the holders. His contention is that he is not personally responsible, but that the bonds should be paid by the Imperial company, as a corporation. In the meanwhile all development and milling is suspended, and will not be resumed until the legal questions involved shall have been adjusted.

SALT LAKE CITY, UTAH

UTAH COPPER REPORT.—OHIO MILL.—PROFITS WITHOUT WORKING.—ONTARIO ANNUAL MEETING.

Although the date for completion has several times been set ahead, it looks as though the Utah Metal Mining Co. tunnel through the Oquirrh range, from Bingham to Tooele, will be completed this spring. This will give the mines of Bingham drainage at depth and will afford facilities for deep mining and of short-cut transportation to the Tooele smelter. The tunnel company expects to gain revenue from transportation and mining privileges, the sale of water and hydro-electric power, and also to develop mineral in a great deal of its own ground. This enterprise, which will prove of great advantage to several of the important Bingham mines, has required a great deal of patience on the part of its backers. Work has been in progress now about three years, and the expenditures to January 1, 1913, were $341,393, according to the annual report. This is in addition to expenditures by previous owners. The total length of the tunnel when finished will be 11,494 ft., of which 908 ft. remained to be constructed January 11. Work on the Bingham side stopped September 21, on account of the strike, and has not yet been resumed. While four-fifths of the distance has been through solid rock, a great deal of running ground was encountered on the Tooele side, impeding progress materially, and increasing the cost. The average cost per foot is given at $16.45, exclusive of overhead charges. A flow of 800,000 gal. of water per day has been developed, which adds to the assets of the company. Several seams of ore have been cut, and these will be prospected after the main work has been finished. When this tunnel has been completed, a number of Bingham properties will be enabled to open their ground at less expense and to reduce their operating costs. E. P. Jennings has been elected president of the company.

Almost simultaneously with the report of the Utah Copper for the last quarter of 1912, showing a deficit of $82,248 after payment of dividends, comes the statement from the operating officials that the mine and mill are again reaching capacity and that a better showing may be expected from now on. It is unofficially stated that the January production of copper was not far from 7,500,000, as compared with 5,975,000 lb. in December. The February production is estimated at 8,000,000 to 8,500,000 lb., and the prediction is made by one of the operating officials that March will show a further increase, although it may be the middle of the year before the company will again reach a production of 12,000,000 lb. per month, which it approached last August. According to the official report, the cost of producing copper for the last quarter of 1912 was 14.83c. per pound, while the

selling price was computed at 15.15c. per pound. This is explained by weather conditions, low production, inexperience of employees hired during and after the strike, suspension of underground mining, consequent lower grade of ore (1.104% copper as compared with 1.41% for the previous quarter), and other reasons. The profits for the quarter are given as follows: Milling profit, $39,273.18; rents, etc., $12,741.42; Bingham & Garfield railway dividends, $175,000; Nevada Copper dividends, $875,437.50; total net profit, $1,102,452.10; dividends paid, $1,184,700; deficit, $82,248.

Ohio Copper has been milling about 2000 tons of ore per day, but this should be increased materially soon, as the second unit of the mill is nearing completion. New rolls, to take the place of the Wall rolls, are being installed, and it is expected two units will be running full time by the end of this month.

The annual meeting of the old Ontario Mining Co. of Park City calls attention to the remarkable situation of this old company, which has been able to live and make money for a number of years without working. Active mining operations ceased some time ago, so far as the company itself was concerned. But it has had a steady revenue right along, and the treasury reserve has been built up to such a point that there is talk of resuming development work in the hope of finding some new orebodies. The Ontario is one of the oldest mines in Utah, and has paid many millions of dollars in dividends from its mining operations, but in recent years its revenue has come from other sources. It owns a half-interest in a coal mine at Coalville, an interest in an electric light plant which derives power from its drainage adit, and the drainage adit itself has been a source of revenue, the Daly-Judge and Daly West mining companies paying a royalty for its use for the transportation of their ores. The Mines Operating Co. has a lease on the dumps and the filling of the stopes, which it is treating by modern metallurgical methods at a profit, and the royalties on lease will not be inconsiderable. With approximately $115,000 cash in the treasury, a steady income from royalties, and a quantity of good ore still in the mine outside of the leased ground, and with a large area of promising territory unprospected, a large number of the stockholders think the old property should be in for a renewal of its youth and activity.

JOHANNESBURG, TRANSVAAL

RETURNS FROM RHODESIA.—FUTURE OF GOLD MINING.—OTHER MINERALS.

Unsatisfactory accounts reach here regarding the condition of affairs in Rhodesia, and while in some details they may be exaggerated, the results obtained in Rhodesia, as proved by figures during the past twelve months, confirm the bad accounts and the previous doubts I have expressed about the mining future of that area. It may be that people are too prone to compare Rhodesia with the Rand, and to regard it as a new and essentially progressive mining country. But it bears no similarity to the Rand and it is by no means a new mining country, being as a matter of fact much older than the Rand. In gold mining it makes but little if any progress; disappointments are the rule in Rhodesia, while on the Rand they are few, and generally due to artificial rather than natural causes. It is true that the gold output for 1912 may show a slight increase over 1911, and may even constitute a record output, but after all these years it is but a poor record, and not by any means the progressive output year in and year out we have been accustomed to see on the Rand.

The fact is that the essential conditions for a successful gold-mining industry do not exist in Rhodesia, where the important and reliable gold producers may be counted on the fingers of one hand, and no amount of puffing either in Rhodesia or London will alter this fact. It is not intended to cast any discredit on such promising and well developed new properties as the Shamva, Cam & Motor, and other well established properties when making such a statement, but these apparent successes are more than discounted by such failures as the Jumbo, Bushtick, Hay, Viking, Buck's Reef, and many others, not forgetting the prospective premature ending of a bright but brief career in the case of the Giant Mines. It is all very well to cling to the hope that the lost orebody at the Giant mine will be picked up, because of the recognition of a basic stringer or even a leader, but this is not the first time similar orebodies have been lost in the same geological formation in South Africa and the connecting stringers and leaders again picked up in depth. But this discovery of a stringer, promising though it may appear, has never resulted so far in the discovery of workable orebodies, and the odds against success at the Giant mine are very great, despite the hopefulness displayed by the geologist called in to advise the company on the matter. These orebodies are very erratic in mode of occurrence, and once lost are difficult to recover. Judging from past results in similar instances, any success attending prospecting operations is more likely to be directly due to good fortune than geological deductions, however hopeful they may seem to be. With respect to the actual progress being made in the gold output of Rhodesia, figures show, however, that after a relapse there has been slight improvement during the past three years; the value of the output for the first eleven months of 1912 being £2,488,706, as against £2,430,869 in the previous year, and £2,368,698 in 1910. The increase during the past three years may not seem striking, but it has been continuous,

SMALL MINE IN RHODESIA.

and when the Shamva and Cam & Motor reduction plants get started and several small but promising mines join the producers it is expected that a more marked improvement will be noticeable. Still, considering the time modern gold-mining operations have been carried on in Rhodesia, the progress has been slow, and it is remarkable how few successful mines have been discovered, independent of ancient workings.

In other minerals, mining progress during the past year has not come up to expectations. It was generally considered that even if gold-mining made little progress the mining of base minerals and metals would increase by leaps and bounds. Such, however, has not been the case during the past year, for, as a matter of fact, there has been a slight set-back. As was generally predicted in these pages, the Victoria tinfields have turned out a failure, but attempts are being made to revive interest in other deposits lying east of Salisbury. Chrome iron has not made the progress anticipated, nor has coal, the development of the latter being of course impossible in a country where development makes such little progress as in Rhodesia. If ever the difficulties surrounding the copper position in Northern Rhodesia are surmounted, affairs in Southern Rhodesia may improve, but the progress anticipated in 1912 has far from materialized.

The discovery of wolfram near Klein Kharas and Nankeis in German Southwest Africa, coupled with the fact that both wolframite and scheelite are known to occur in several places in southern Rhodesia, should serve to direct attention to the possibilities of tungsten production in South Africa. The tungsten market may easily be overestimated, however.

TORONTO, CANADA

Pearl Lake Discovery.—Large Bullion Shipment.

The most noteworthy happening in Porcupine lately was the cutting of a big vein in the Pearl Lake at the 600-ft. level, where it confirmed the expectations of the management, both as regards width and gold content. The ore is officially stated to average $30 per ton, as at the 400-ft. level. The shaft is being sunk to the 800-ft. level. A stamp-mill with a capacity of 300 tons per day will be erected immediately. The proving of the vein in depth has had a favorable effect on the market for Porcupine shares, which has been somewhat quiet with a declining tendency.

Although the leading mines claim to have their full quota of men, the persistence of the strike is retarding development work on other properties, many mine-owners deferring operations until matters are finally settled. As was to be expected, the heavy sentences given three of the strikers have accentuated the bitter feeling between the employers and the men, and the labor organizations throughout the country are making common cause with the miners. Strong remonstrances against the imprisonment of the convicted miners were made to the Canadian and Ontario governments, as a result of which the three prisoners, two of whom had been sentenced to fines of $500 and one to $50, which they were unable to pay, were set at liberty on tickets-of-leave pending the result of an appeal. These conditions do not augur favorably for the speedy return of industrial peace and stability.

The new mill of the McIntyre has been completed and is in operation. There is a large supply of ore on hand for treatment and the output is expected to be not less than $70,000 per month. A 5-stamp mill has been shipped to the Tough-Oakes claims at Kirkland lake in the Swastika district, owned by C. A. Foster, of Haileybury. A compressor is being installed and a new main working shaft will be sunk. The Hughes property in the same district has shipped 25 tons of high-grade ore. The Lucky Cross has completed its mill building and the machinery is on the way. Five stamps will be installed at first and five added later. C. E. Wettlaufer and L. E. Wettlaufer, of Buffalo, have taken a working option on the James properties, also known as the Maloof-O'Connor claims, in Shaw township.

The largest shipment of bullion that ever left Cobalt was made February 11, comprising 163 bars containing 308,997 oz. of silver, valued at $187,665. The largest consignment came from the Nipissing, being 214,206 oz., worth $132,807. It was sent to the London market. The Timiskaming has made an important discovery at depth, consisting of a vein 7 to 10 in. wide at the 575-ft. level in the diabase. The Cobalt Aladdin company, of London, which is now working the old Silver Queen, has secured a controlling interest in the Chambers-Ferland. At the latter mine a stringer that was being followed in a raise from the eastern cross-cut widened to a 4-in. vein of decomposed cobalt carrying high silver contents. The find was made immediately after passing the contact between the Keewatin and the diabase.

The annual meeting of the City of Cobalt took place on February 5. The manager's report showed that there was in sight approximately 1,269,662 oz. of ore above the 400-ft. level. The ore hoisted during the year amounted to 8675 tons at a mining cost of $4.10 per ton. The directors were authorized to raise funds for the construction of a mill. The royalty payable to the Ontario government has been reduced from 25% of the net profits to 5%. The new English owners of the Cobalt Lake have registered it in London under the name of the Cobalt Lake Silver Mining Co., Ltd., capitalized at £300,000 in £1 shares. The company has adopted the 9-hour day schedule. M. L. Foley, who with an English syndicate recently took over the Calcite Lake property in the Elk Lake district, is arranging for the installation of a 50-ton mill. Another rich vein of high-grade ore has been cut at the 200-ft. level on the Mann, Gowganda district. Machinery for the new plant is arriving at the Beaver auxiliary, formerly the Donaldson, at Elk Lake. It will have two 8-drill compressors run by a battery of boilers. The new shaft, now down 110 ft., will be continued for another 100 ft. before driving is undertaken.

LONDON

Mining at Hampden Cloncurry.—Cobalt Town Site.

In the *Mining and Scientific Press* of January 4, Thomas T. Read, in his review of the progress of the metallurgy of copper, presents a diagram of the production of copper in Australia, and its metallurgical and commercial distribution. I wish more information such as this were available relating to the actual marketing of all sorts of metals. Times move rapidly even with copper, and Mr. Read's diagram is already out of date, for the Hampden Cloncurry mine started production last July with blast-furnaces and converters. The contract for the output of blister copper has been given to Brandeis Goldschmidt & Co. As the position of the Hampden Cloncurry is evidently not known in America, some notes of its history may be of interest. The company owning the Hampden and Duchess copper mines, in the Cloncurry district of North Queensland, was formed by the Baillieu group, in Melbourne, in the year 1906. More recently the Trekelano and Mascotte properties have been purchased, and three months ago negotiations for the MacGregor claims were begun. In 1909 the company was reconstructed and additional capital subscribed. Smelting was started in April 1911, and the matte was then sold to the Mount Elliott company. Attention has recently been centred on the completion of the smelting plant. This was put in commission on July 16. It contains two blast-furnaces, one measuring 84 by 42 in., and the other 168 by 42 in.; and two converters. During the run from July 16 to August 31, the smelters treated 2580 tons of Hampden ore averaging 8% copper, 2906 tons of Duchess ore averaging 18% copper, and 79 tons of purchased ore. The resulting blister and matte contained 670 tons copper, 268 oz. gold, and 7074 oz. silver. Hardly any development has been done lately owing to the stress of work connected with the completion of the smelter. As regards ore reserves, these are estimated as follows: Hampden, 88,000 tons averaging 7¾% copper; Duchess, 80,000 tons averaging 16%, and 56,000 tons averaging 5%; Trekelano, 12,000 tons averaging 14%; Mascotte, 2500 tons averaging 16 per cent.

After many years of disappointment, the Cobalt Town Site Silver Co. has achieved success and paid a handsome dividend. It is gratifying to Englishmen to find that this, the only mine at Cobalt owned in England, has become profitable. The Casey Cobalt, owning a property at New Liskeard, farther north, belongs to the same group, and recent developments have proved encouraging. The meetings of these two companies were held this week, and the speeches were unusually interesting. English investors were slow to appreciate the profitable nature of the silver deposits of Cobalt. They feared that the excessive richness of the ore betokened a shallow and a sporadic distribution of the silver. Events have proved that such timidity, although reasonable, was exaggerated, for the mines of Cobalt have prospered exceedingly and the exploitation of them has enriched many people, notably a dozen men who have become millionaires. Even after the district had passed the first stage of immaturity, it was held that the geological conditions were unfavorable to the persistence of the ore in depth, for the veins appeared to become impoverished when they were followed below the diabase and the Huronian conglomerate into the Keewatin schist. At the Casey Cobalt meeting it was asserted by Mr. Parker that rich ore had been followed in the Beaver mine down to 700 ft. through the Keewatin and into the diabase. This view is in accord with the views expressed by Willet G. Miller, the Provincial Geologist, and by others who have studied the local conditions. They have held that the veins were enriched when in the diabase or near it, so that the significant feature of the Beaver discovery is not that the ore is in the Keewatin but that the Keewatin is traversed by a deeper sill of diabase, producing conditions found favorable elsewhere in the district. However, it is gratifying to learn that such conditions are repeated in depth. While 700 ft. is not really deep, to the eye of modern mining, it is so much farther from the surface than the shallow workings of the bonanza zone as to be highly encouraging to those who propose to explore deeper.

General Mining News

ALASKA

FAIRBANKS

According to the *Tanana Magazine*, an interesting 'Quartz' edition of the *Fairbanks Daily Times*, little consideration has been given to the lumber question in the district. During the past three years 11 properties of fair size and several smaller ones have used 900,000 ft. of lumber in the mills and mines,. In 1910 the price was $30 per M, but at the end of 1911 this was raised to $40. To the cost of $35,000 for the above lumber was added about $25,000, owing to long wagon haul. Some rafts of logs have come from the Big Chena river, and this year all the available trees on the Chena and tributaries will be cut. They nearly all grow along the banks of streams. About 2,000,000 ft. has been cut at the Salchaket river, while on the Tanana river, below Fairbanks, there is a large quantity of good timber.

The gold output of Tanana in 1912 was $4,793,700, of which $200,000 came from quartz crushed in the various mills. A one-third interest in the lease of the Rexall property at the head of the Cleary tributary has been sold for $3500. There are four claims, and a 2-stamp mill. On the Rexall claim an adit has been driven 500 ft., and two winzes sunk on the vein. Six men are working on Lost Horse creek; the depth of bedrock varies from 16 to 50 ft. On upper Fairbanks creek there is a little gravel being hoisted to the surface during the winter. For the Mihalcik claim on Ready Bullion creek, 600 more logs are to be hauled for this year's work. Bedrock in this property is at 40 ft., and gravel will average 150 ft. in width. There is a good-sized dump on the surface, which could not be sluiced last spring owing to shortage of water. The Newsboy mine has enough ore on the 315-ft. level to keep its 5 stamps working continuously. From 35 tons, gold worth $800 was recovered. The Homestake company treated 22.5 tons of ore at the Newsboy mill, averaging $77 per ton. This ore came from a vein in an adit, about 300 ft. in, and ore has been opened for a distance of 200 ft. Enstrom Brothers, on Eva creek, have reached bedrock. The shaft is down 130 feet.

SLUICING A WINTER DUMP, FAIRBANKS.

IDITAROD

All work is practically at a standstill owing to the cold weather. The minimum temperature recorded is 52° below zero, while 40° below has been common.

JUNEAU

During December the Alaska Mexican mill worked 29.76 days, and crushed 18,343 tons of ore, which yielded $41,151 from free gold, and 405 tons of concentrate. Operating expenses were $24,005, and construction $7313, and the profit was $9421. Development covered 299 ft., and the stock of broken ore decreased 3352 tons. In 1912 the 120-stamp mill crushed 233,659 tons averaging $2.87 per ton.

The Alaska United mills worked 29.51 and 29.70 days, respectively, crushing a total of 35,467 tons, which yielded $81,627 from free gold, and 900 tons of concentrate. Operating expenses were $50,337, and construction $8300, leaving a profit of $22,173. Development in the Ready Bullion claim covered 370 ft., and in the 700-Ft. Claim 68, the stock of broken ore decreasing 11,854 and 506 tons, respectively. In 1912 the two 120-stamp mills crushed 450,147 tons averaging $2.60 per ton.

At the Alaska Gold property ore has been cut in the Sheep Creek adit, two miles from where a considerable amount has been opened. At the present rate of progress this main haulage-level should be under the main workings about June 1914. At the Perseverance mine 200 men are employed developing ore. One 3000-hp. hydro-electric station is in operation. This is the Salmon creek plant, which will develop 6000 hp. when finished. The second station of 3000 hp. is also well under way. Between the mine and millsite there is a difference in elevation of over 2000 ft. The destruction of the old Perseverance mill has hindered treatment studies, but experiments are being made in another small mill. In the summer work will be pushed on the big mill; the site is now being cleared.

VALDEZ

The Alaska Water, Light & Telephone Co. will construct an electric lighting plant to cost $30,000. It will consist of a 500-hp. Pelton-Francis turbine, driven by water coming through a 30-in. wood-stave pipe from Solomon basin, and a modern generator and other accessories.

ARIZONA

COCHISE COUNTY

In the Hoatson shaft of the Calumet & Arizona a body of sulphide ore about 35 ft. wide, worth 6% copper, has been opened. There is good reason to believe that this company will acquire the Saginaw property. Shipments of lead-silver ore from the Shattuck mine to El Paso have returned $20 per ton.

MARICOPA COUNTY

The Monarch mill at Wickenburg is in full operation, the pipe-line delivering plenty of water. The resumption of work at this property means a good deal to the town.

PIMA COUNTY

The Twin Buttes mine is employing 30 men, and ore is sent regularly to the Pioneer smelter. The Empire Zinc Co., which took over the old San Xavier claims, has 25 men at work. High-grade carbonate of zinc ore is being hoisted, and will be sent to Canon City, Colorado. The Olive Mines Co. is erecting a concentrator. Silver-lead ore is being opened at 260-ft. depth in one claim. Considerable work is being done in the Helvetia district.

YAVAPAI COUNTY

In the Copper Basin district a syndicate has driven an adit 320 ft., intersecting four veins. A shaft has been sunk over 60 ft., and a cross-cut from this has passed through 11 ft. of silver-lead ore worth $57 per ton. The Jerome Oil Co. has received a supply of casing, and will resume drilling. The oil stratum is expected at about 400 ft. The Breed group of mines, near Senator, which was taken over last year by the New Mexico Lead & Copper Co., is opening well. The Effie shaft is down 40 ft., and has cut 4 ft. of heavy copper pyrite and galena ore. This ore disintegrates quickly on exposure to the air.

YUMA COUNTY

(Special Correspondence.)—Black Hills people have organized the Arizona Mining Co., taking over a large acreage of copper property in the Hacquavar mountains, south of Wenden. The board of directors comprises Seth Bullock, president; T. G. Grier, vice-president; Chambers Kellar, secretary; R. H. Driscoll, treasurer, and H. Nevin, of Yuma. Present development is showing good orebodies carrying copper and gold. It is proposed to ship to the Swansea smelter, which can be reached in about 32 miles, 12 of which would be a wagon or motor-truck haul, and the rest by rail. Patenting of about 15 claims is to be pushed at once.

Wenden, February 14.

CALIFORNIA

Butte County

The California Diamond Drill & Engineering Co. has begun work at Magnolia, in sinking a series of holes to a depth of 500 ft. This work is being done for a syndicate of San Francisco people. The Hupp mine has been forced to suspend work temporarily on account of the large quantity of water coming in. The Blue Hog has also been shut down. About 20 men were employed at both mines. Good ore has been cut in the McClung-Kincaid mine at Berry creek.

Calaveras County

The concentrator at the Calaveras mine, Copperopolis, is making a saving of 80% of the metal content of the ore. Five cars of ore, 227 tons in all, were shipped, averaging from 9.15 to 10.92% copper, net returns being $4570.

Modoc County

(Special Correspondence.) — Development in the High Grade district has been seriously handicapped of late by the snowstorms and cold weather, but several companies continue to conduct work in a small way. The Modoc Mines Co. has two shifts steadily employed, and the shaft is nearing the 200-ft. level. In the latter workings a 6-ft. vein has been intersected by the west drift. Some of the quartz is said to assay $50 per ton. Lessees are also busy on Modoc ground. The Sunset-Hummer company is preparing to make an early shipment of high-grade ore, and about 100 tons are available. The main vein is stated to be 8 ft. wide. The shipping grade averages over $50 per ton. The Lucky Dutchman lease on the Sunshine is planning to send the 60-ft. shaft deeper and extend a crosscut to tap the vein outcropping on the surface. The lease is controlled by the Spearmint Mining Co., composed of Colorado people. Several rumors concerning the plans of the Ft. Bidwell Mines Co. are in circulation. A contract has been let for driving 200 ft. of drifts from the Sugar Pine adit, and it is reported this adit is to be extended to the Mountain View claim. The management is further said to be considering employing the adit for transportation of ore to the mill in winter, the operation of the aerial tramway being attended with difficulty because of the severe snowstorms. The Sunshine-High Grade is working in a small way. Several companies are preparing for extensive operations with the advent of spring, and it is believed that summer will record vigorous work at most of the larger properties.

Ft. Bidwell, February 13.

Nevada County

About 30,000 tons of tailing from the Pennsylvania mill has accumulated on the Larkin property, southeast of Grass Valley, and it is proposed by H. Rhyne and P. Eastman to treat this dump. The Pennsylvania Mining Co. is now treating its current tailing. Men are at work on Deer creek, about 300 yd. below the Broad street bridge, and are working gravel in a sluice-box about 40 ft. long.

Placer County

The King Gold mine, three miles east of Roseville, has been incorporated for $100,000. It contains ore averaging $15 per ton; also black sand in a channel 50 ft. deep and 100 ft. wide, which is stated to be worth $4 per ton in platinum.

Plumas County

Six men have started at the Pettinger mine, near Taylorsville, and an adit will be driven 500 ft. during the summer. This mine is owned privately, and A. L. Beardsley is in charge.

Shasta County

Six miles west of Redding the Shasta King company is developing its mine, and making shipments of silver ore to the Selby and Kennett smelters. A drag-line excavator is to be used to handle gravel in the Russell tract, near Igo. Machinery ordered will cost $15,000. The property, operated by the Thompson-Porter interests under bond, comprises 500 acres, and if profitable it is probable that the Bryant ranch of 1300 acres will be acquired. The new 5-stamp mill at the Moonlight mine, near Ingot, started on February 13. It is driven with power supplied by the Northern California Power Company.

Sierra County

It is reported that the Tightner mine at Alleghany is producing rich ore, and sinking will be done on the ore-shoot. The water-power for the Fruitvale mine, on the Middle Yuba river, was frozen up in January. A raise is being driven on a shoot about 100 ft. from the face of the adit, which is in 700 ft. A cross-cut went through 40 ft. of mineralized ore. All the miners of the Tippecanoe section of Pike City district have stopped work for the winter, except Hartman & Son, who will develop the Gilt Edge lode.

The adit in the Herkimer property, south of Bunker Hill, is in hard lava, but it breaks well, and 100 ft. is being driven per month. Work is to be resumed at Brandy City, as water has been got there again. About 50 ft. of the Gold Bluff North Fork ditch broke away above Sweetwater, and a flume will be built in its place. Development in the Sierra del Oro, or Ironsides adit, has opened the ore-shoot 125 ft. below the bottom of the shaft. The ore carries free gold and arsenical pyrite.

Tuolumne County

(Special Correspondence.)—The Josephine mine, situated between the Shawmut and Jumper, on the Mother Lode, was bonded this week to W. P. Jones, representing Eastern capitalists, who states that machinery has been purchased and that the sinking of a new shaft to a depth of 300 ft. will begin at once. Mr. Jones will be superintendent. Upward of $100,000 was taken out of the property in early days. Charles Gillis and associates have taken out gold to the amount of nearly $3000 from the Old Wilson mine on Jackass hill, near Tuttletown, during the past few days, and the prospects for more are reported as being good. The property has yielded aproximately $160,000 to date. The property of the Horse Shoe Bend Mining Co. was sold at sheriff's sale this week to George Morrice, judgment creditor, for $15,000. The Gold Crater mine, at Jupiter, has also been sold to satisfy a judgment. It was bid in by George Mundorf, a Sonora merchant, for $4336. The New Providence Mining Co. will begin milling ore next week. For more than two years the company has done nothing else than develop the property, and a large supply of ore is on hand.

Sonora, February 8.

COLORADO

Clear Creek County

The Terrible and Dunderberg mines have been consolidated, and will be worked under one management. They were recently examined by Boston people. The Terrible shaft will be pumped out in the spring and sunk further. The Golden Glory adit, above Empire station, is in 1509 ft. It cuts the Jo Reynolds-American Sisters system of veins. Two cars of lead ore per week is being sent to the Salida smelter from the Santiago mine at East Argentine. In 1912 the Capital mines output was $49,103 more than in 1911, and it is expected the total will be $500,000 for the current year. Swanson & Co., in a lease below the adit-level of the Bellevue-Hudson, are mining ore from a vein 8 to 24 in. wide, carrying 50% lead and over 400 oz. silver per ton. Shipments are being made from the Josephine, Tobin, and Hummer & Herber leases.

Ouray County

The Mountain Top cross-cut was driven 377 ft. in January, there remaining 1442 ft. to be driven to cut the vein. This is said to be a record for cross-cutting in unaltered andesitic breccia of the San Juan. The rock drills well, but breaks badly. The total cost was $14.76 per foot driven.

Pueblo County

Besides having steel works of 500,000-ton annual capacity, the Colorado Fuel & Iron Co. has three iron mines in Colorado, Wyoming, and New Mexico, 25 coal mines, and 2 railroads. During 1912 the works produced 485,743 tons of finished products worth $15,140,523, the net earnings being $2,766,775. The chief market of this company is in

the Central and Western states, where it does not come into keen competition with large Eastern concerns of a similar nature.

TELLER COUNTY (CRIPPLE CREEK)

It is proposed to alter the capitalization of the Golden Cycle Mining Co. from 1,500,000 shares of $1 each to 300,000 of $5 each. In the Eclipse lease of the El Oro Mining & Milling Co., at a depth of 75 ft., 15 ft. of ore worth $20 per ton has been opened. During 1912 the Elkton Consolidated M. & M. Co. made a profit of $215,000, of which $150,000 was paid in dividends.

IDAHO

IDAHO COUNTY

The Little Butte mine, 6 miles from Elk City, is opened by an adit 1000 ft. long, and a high-grade ore-shoot was cut at 200 ft., while at 600 ft. a winze opened 4 ft. of good ore, which is being sent to the Washoe smelter at Anaconda. A one-stamp mill on the property concentrates the second-class ore. The Mother Lode claim, 1½ miles from Elk City, has a vein 8 ft. wide, and the custom mill is kept busy on this ore.

SHOSHONE COUNTY

The Burke ore-train, which leaves Wallace at 6 p.m. over the O.-W. R. & N. Co.'s line, to haul ore from mines at Burke and Mace to the various mills, got beyond control on February 8, and after rushing down a 4% grade, the engine and three ore-cars jumped into the gulch, 200 ft. below. Nobody was badly hurt, the train crew having jumped into deep snow.

The Stewart Mining Co. is employing 250 men at the mine near Kellogg and the Mammoth mill at Wallace. Net monthly earnings are $60,000. An adit will be driven 200 ft. into the North Bunker Hill property near Wardner, to cut the orebody found in the upper workings of the Caledonia. Machine-drills will be used, the contract price being $5 per foot.

The Federal Mining & Smelting Co. has been experimenting for some time on treatment of the zinc ores of its mines, the loss in past years being heavy from these ores. At the Green Hill-Cleveland mill, formerly the Standard, at Mace, the flotation process is being tried with success.

MICHIGAN

HOUGHTON COUNTY

Copper production of the Lake Superior mines in January was as follows: Ahmeek, 1,273,610 lb.; Allouez, 603,210; Baltic, 1,502,000; Calumet & Hecla, 5,095,262; Centennial, 243,295; Champion, 2,440,000; Franklin, 366,000; Isle Royale, 633,853; Osceola, 1,674,465; Superior, 274,050; Tamarack, 631,765; Trimountain, 1,004,000; and Wolverine, 964,000 pounds.

IRON COUNTY

The Hollister Mining Co., Crystal Falls, will install a 625-kva. Curtis turbo-generator in its power-plant. In the installation are included a 50-kw. generator, 150-hp. motor, Tirrill regulator, three 20-kva. transformers and switchboard, also two 4-ton electric mining locomotives. All the apparatus has been ordered from the General Electric Co. The Cleveland Cliffs Iron Co., Ishpeming, will install in the Lloyd mine at Morris a 100-kw. motor-generator set and three 6-ton electric mining locomotives in the Ishpeming mines. The orders for this apparatus have been placed with the General Electric Company.

MINNESOTA

ST. LOUIS COUNTY

The Pittsburg Iron Ore Co., Mountain Iron, will equip its mines for driving the machinery by electric power with 12 new motors ranging from 15 to 50 hp., supplied by the General Electric Company.

MONTANA

MADISON COUNTY

(Special Correspondence.)—There is talk of resumption at the mines of the Green-Campbell Mining Co. near Silverstar.

Silverstar, February 12.

PARK COUNTY

(Special Correspondence.)—The troubles of the Yellowstone Portland Cement Co. seem to have been adjusted, and it is reported that the plant will be completed and in operation this summer. The company, a $6,000,000 corporation, has already spent a large amount in preparing the ground for operation. The limestone will be obtained from a huge deposit of travertine, precipitated by ancient hot springs. This deposit is pure white calcium carbonate, from which a white cement can be made.

Livingston, February 12.

RAVALLI COUNTY

(Special Correspondence.)—The Montana Mines Co. cut rich ore in its property near Florence, on the east side of the Bitter Root valley. The ore assays well in gold and is free milling.

Florence, February 12.

SILVERBOW COUNTY

(Special Correspondence.)—A fire has made its appearance in the West Colusa mine of the Anaconda Copper Mining Co., and before it is completely subdued promises to do considerable damage. Just how it originated is unknown, as the mine was not being worked, having been closed down to equip the engine for operation by compressed air. The belief of B. H. Dunshee is that the fire was caused by spontaneous combustion in some of the abandoned workings on the 500-ft. level. The Mountain View mine has ventilation connections with the West Colusa, with the result that the smoke and gases entered that property to such an extent that about 50 men were overcome, but they were quickly taken to the surface and no serious results followed. When it was found that the fire was likely to prove serious, all the men in the Mountain View were sent to the surface, and work probably will not be resumed in that property for some weeks. The mine employs 650 miners. The extent of the fire will not be exactly determined for some days, and it is quite probable that it has reached the 600-ft. level. The West Colusa is the most heavily timbered mine in the district, and for this reason it is going to be hard to control the flames. A large force of men under the direction of Jack O'Neill is engaged in fighting the flames, and the Anaconda officials are confident that they will be able to confine the fire at a point not lower than the 600-ft. level.

Butte, February 14.

Butte & Superior will produce 5,000,000 lb. of zinc concentrate in January, while March is expected to have an increase of 50%. About 550 tons of ore is being treated daily in one unit of the mill, and extraction is reported at 80%. The total capacity of the mill will be 1200 tons per day.

NEVADA

ESMERALDA COUNTY

The St. Ives shaft of the Goldfield Merger Mines Co. is down below the 1450-ft. level, the country varying considerably in hardness. At the Sandstorm-Kendall, additional pumping machinery has been installed. At the 1400-ft. level of the Grizzly Bear mine of the Goldfield Consolidated Mines Co., a strong flow of water has retarded work. In the Combination mine a cross-cut is being driven at a depth of 250 ft., to cut the orebody opened recently on the 130-ft. level.

A shipment of good coal has been received at Goldfield from the Nevada Coal & Fuel Co. property at Coaldale. A flat coal seam has been opened for 500 ft. on its dip, making a vertical depth of 100 to 150 ft. Near the bottom the seam was disturbed by a fault, but was picked up 30 ft. lower.

HUMBOLDT COUNTY

On February 11 the Charleston Hill National Mining Syndicate, defendants in the recent suit at National, transferred to the National Mines Co. the West Virginia No. 1 and Charleston No. 1 claims, known locally as the 'Mammoth' properties. The terms are not known, but this means a final settlement of the case. The National Mines Co. has finished the station in No. 5 adit.

After driving a 1500-ft. adit, N. P. R. Hatch has cut

4 ft. of ore in his lease on the Mayflower National property. High-grade silver ore is being sacked from a lease on the Cheefoo lode by Walker Brothers. The Kennedy-MacDonald Mining Co. is driving an adit to cut a vein already opened in its Indian Valley adit.

LYON COUNTY

The Nevada-Douglas mines produced 1,114,691 lb. of copper in January, from 22,279 tons of ore. The Ludwig mine averaged 4.7% and Douglas Hill 3.6% of copper. The Mason Valley smelter received 26,000 tons of ore during January. Matte production was 2328 tons and copper 1,658,000 pounds.

NYE COUNTY

The Tonopah Mining Co. has installed spraying apparatus in its mines to keep down the dust made in drilling. It only requires from 5 to 10 gal. per shift., does not interfere with operations of the miners, and costs about $5 each. In January the mill treated 14,720 tons of ore yielding bullion worth $197,700, and 110 tons of concentrate worth $41,850. The net profit was $130,143. The Belmont treated 12,517 tons yielding 304,734 oz. of bullion, the profit being $150,485. The mines at Tonopah, during the week of February 15, produced 11,297 tons of ore valued at $237,110, the yield for the current year being 75,238 tons and $1,573,530. The Jim Butler yielded 1684 tons in January and a profit of $20,612.

STOREY COUNTY

At the Virginia City School of Mines, according to the biennial report recently issued, there are 38 students receiving instruction, including the 16 members. At the Comstock, it is proposed to reopen the old connecting drift on the Ophir and Con. Virginia 2500-ft. level, to connect with the 2500-ft. station of the C. & C. pumping shaft. Pumps will be installed in the old Ophir-Mexican winze to lower the water below the 2500-ft. level. No. 1 hydraulic elevator in C. & C. shaft is to be removed; and the centrifugal pump moved to the centre compartment. During the week ended February 15, 1575 tons of ore was hoisted from the Mexican, worth $46,302. The mill treated 522 tons worth $32.95 per ton. On the 1600-ft. level of the Ophir the northeast drift was extended 35 ft. from 600 ft. north of the C. & C. connection in the north lateral Sutro tunnel, and shows porphyry, clay, and quartz of fair value.

NEW MEXICO

GRANT COUNTY

The Guggenheim Exploration Co. has taken an option on the Cleveland group of five claims in the Pinos Altos district. The property contains zinc ore. The annual report of G. H. Utter shows that he shipped 3,100,000 lb. of concentrate in 1912.

SANTA FE COUNTY

(Special Correspondence.)—The Denver mine-rescue car

MINE RESCUE CAR.

of the Bureau of Mines is making the following tour. On February 9 it arrived at Berwind, Las Animas county, and remained there 6 days; on February 16 the car went to the Broadhead mine, at Aguilar, in the same county, stopping there 6 days; then will remain at Frederick, Weld county, from February 23 to March 1. The car then goes south to the Albuquerque & Cerillos Coal Co.'s mines near Madrid, Santa Fe county, New Mexico, and will stop there 6 days; next going to the Carthage Fuel Co.'s mines, near Carthage, Socorro county; and after 6 days will go to Gallup, McKinley county, and remain 20 days at the mines of the Diamond Coal Co. and Victor-American Fuel Company.

Pittsburg, Pennsylvania, February 10.

TENNESSEE

POLK COUNTY

During the year ended December 31 last, the Tennessee Copper Co. produced 13,252,634 lb. of copper, and 195,000 tons of sulphuric acid. The profit from these products, custom ore, and miscellaneous revenue was $1,200,000.

TEXAS

REEVES COUNTY

According to information from Pecos, a rush which is not justified by present development has set in for that district, and many claims have been staked.

UTAH

JUAB COUNTY

During January 900 ft. of development was done in the Chief Consolidated mine, and 8000 tons of ore and waste was hoisted. The main shaft is down 1800 ft., and water-level should be reached in 30 days. The Gold Chain shipped 600 tons of ore in January, and has paid a dividend of 3c. per share, totaling $30,000. In the Iron Blossom a drift is being driven in a westerly direction from the 1900-ft. level toward a vein which was cut on the 1700-ft. level. The May Day is shipping one car of ore per day.

SALT LAKE COUNTY

The Utah Copper Co. treated 930,595 tons of ore during the last quarter of 1912, 95% being mined by steam-shovels and 5% from underground. Copper production was 12,906,582 lb., the year's toal being 96,175,090. The average grade of ore during the quarter was 1.104% copper, and cost 14.83c. per lb. Owing to the strike, operation was largely affected. The profit was $1,102,452, and dividends were $1,184,700, leaving a deficit of $82,248. All power for the Arthur plant is supplied by the Utah Power & Light Co., also one-quarter of that for the Magna plant, a corresponding portion of the Magna steam power-plant having been stopped.

At the beginning of the current year the Utah Copper Co. employed 1547 men, as against 1322 in November. The January tonnage of ore is estimated to be 450,000 tons, the average daily tonnage up to January 20 was 14,000 tons. The Arthur and Magna plants are handling 8000 and 10,000 tons per day, respectively.

The Utah Metal Mining Co. states that the tunnel from the Tooele side of West mountain is in 8616 ft., an advance of 2072 ft. during 1912; and from the Bingham side on September 21 was 1970 ft., an advance of 1585 ft.; the total to date being 10,586 ft., leaving 908 ft. to be driven. In 1912, $98,787 was spent, and to date $341,393, the average cost in 1912 being $16.45 per foot. The tunnel makes 800,000 gal. of water per day.

SUMMIT COUNTY

During the past year the Tintic Central Mining Co. confined work to the 920-ft. evel. At 200 ft. from the shaft a large body of quartz was cut, which gave assays as high as 61 oz. of silver per ton. Development covered 1226 ft. Cash on hand January 1, 1913, was $498.

WASHINGTON

FERRY COUNTY

Ore shipments over the Spokane & B. C. railway for the two weeks ended February 7 were 705 tons, of which 493 were from the Ben Hur mine. The Hope Mining Co., after considerable idleness, has resumed work, and

made a shipment of 40 tons. The Washington Water Power Co. has finished sampling the Surprise, Republic, Ben Hur, and San Poil mines. The Ben Hur Leasing Co. has produced ore worth $44,000 in 11 weeks. A 14-drill air-compressor has been delivered at the mine, also a new boiler. The Fan Lake Mining Co. has been incorporated at Spokane with a capital of $1,500,000.

STEVENS COUNTY

From 80-ft. depth of the new shaft in the Standard Chewelah mine, copper glance ore has been cut, worth $50 per ton. When the new machinery is installed the main shaft will be pumped out, and a cross-cut driven to cut the new ore at 200-ft. depth. Ore in the June-Echo is improving in value.

On the 520-ft. level of the Copper King, at Chewelah, high-grade copper ore has been opened, and shipments will be started in a few weeks.

WYOMING

ALBANY COUNTY

In his biennial report, C. E. Jamison, State Geologist, states that he will make an examination of Centennial, in this county. To investigate the oil and mineral resources of other districts, and prepare geological maps, will take two years and cost $15,000.

CANADA

BRITISH COLUMBIA

(Special Correspondence.)—Spokane interests are opening a good silver-lead district at the head of the Tulameen river. There are several promising claims near the government wagon-road between Leadville and Tulameen City, the latter being a government townsite 20 miles below the former place, on the stage-road between Princeton and Merritt. The Great Northern Railroad Co. has 3 steam-shovels working on its main line up Otter creek to Tulameen. The Canadian Pacific Railroad Co. has applied for a charter to build a branch line to Leadville. About 5 miles from Tulameen there are quantities of peridotite said to contain platinum. Bear Creek is 12 miles away, and will probably develop into a good copper centre.

MAP OF BRITISH COLUMBIA.

Leadville, February 14.

From the first year's development and shipment of 670 tons of ore from the Utica Mines, Ltd., near Kelso, $67,000 gross and $54,155 net was received. A dam has been constructed giving a head of 300 ft., from which 150 to 200 hp. can be obtained. In the War Eagle mine, between the 1200 and 1500-ft. levels, a silver-lead orebody 30 ft. wide has been opened, which is said to be the best yet discovered in British Columbia.

SONORA

In January the Cananea smelter produced 9,000,000 lb. of copper. Shipments through the port of Agua Prieta from mines in the northeastern part of the state were 14,031 tons, valued at ₱2,383,600.

In 1912 the Cananea Consolidated Copper Co., known locally as the 'Four C.,' produced 54,000,000 lb. of copper, while this year's output is estimated at 90,000,000 lb. The present cost of treating a ton of ore is about $2.50. After three months idleness, the Calumet & Sonora mine is in operation. Up to September 30, 1912, the past year's production was 1161 tons of copper concentrate, which contained 2.3 oz. of silver and 11.41% of zinc. Zinc concentrate totaled 1834 tons, averaging 45.70% of zinc. Lead concentrate amounted to 747 tons, containing 63.55% of lead, 31.29 oz. of silver, and 0.94% of copper. These products were smelted at Cananea, Oklahoma, and El Paso, respectively. The net earnings were $98,513. The shaft is down to 525 ft., and on the 300-ft. level a good deal of ore has been broken. W. H. Weed is consulting engineer, and W. H. Tangye, superintendent. The Democrata Mining Co. blew in its 250-ton furnace in December, and during 1912 produced 1,500,000 lb. of copper, but in 1913 will probably yield 18,000,000 lb. The Mexican Metals Co. has been working all the past year, and is now treating 100 tons of ore per day. El Pilar mine, of the Arnold Mining Co., 35 miles northwest of Cananea, will build a 50-ton concentrator, while the Arizona-Sonora company may erect a 50-stamp mill. In the Moctezuma district the Moctezuma Copper Co., at Nacozari, made about 600,000 tons of concentrate, which was smelted at Douglas.

Obituary

GEORGE WILLIAM MAYNARD, a distinguished metallurgist who is best known for his work in introducing the Thomas basic steel process in United States practice, died in New York on February 12. He was born in Brooklyn, June 12, 1839, and studied at Göttingen, Columbia, Royal School of Mines, and Clausthal. After a brief experience as a mine manager in Ireland, he went to Colorado. He served as professor of mining and metallurgy in Renssalaer Polytechnic Institute from 1868 to 1872. For the succeeding six years he served as consulting engineer to steel works in England and copper smelters in Russia, and in 1880 established himself as consulting engineer in New York, where he took a prominent part in the development of the metallurgical industry. He was one of the original members of the American Institute of Mining Engineers and was prominent in a number of other scientific societies, both at home and abroad.

MAX BOEHMER, who died at Denver, Friday, February 14, was one of the best known and best liked of the coterie of engineers that has long made Denver a centre for mining men. Born in Luxemburg in 1847 in an influential family, he received his education at the Polytechnic Institute at Hanover, graduating as a mining engineer in 1869. Shortly thereafter he came to the United States and, serving first with the engineering corps of the U. S. Army in the Mississippi river, to Leadville in 1879. Here he met D. H. Moffat, with whom he was intimately associated for many years. At various times he was connected with most of the large mining companies in Colorado and with many in Idaho, Nevada, Utah, and elsewhere. Two weeks ago, while sampling an incline in the Bunker Hill & Sullivan workings he, as he thought, strained his shoulder, but neither he nor the physician consulted in Denver considered the matter serious. His death, resulting apparently from heart trouble, was entirely unexpected. Mr. Boehmer leaves a widow and two daughters, one the wife of George Argall, and a son, Max Boehmer, Jr., who is a student in the School of Mines. He was a genial likeable man and an able conscientious engineer who stuck close to his work and he leaves a clear record and honorable name.

Market Reports

LOCAL METAL PRICES

San Francisco, February 20.

Antimony	12—12¾c	Quicksilver (flask)	40
Electrolytic Copper	18—18¼c	Tin	53¾—54c
Pig Lead	4 60—5.55c	Spelter	8¼—8¾c

Zinc dust, 1400 lb. casks, per 100 lb., small lots $9.50—9.75; large $7.50—8.50

METAL PRICES

(By wire from New York.)

NEW YORK, February 20.—Copper prices are declining; large sales have now steadied market. Lead remains unchanged and spelter is still weak. Average daily prices for the past week, in cents per pound, based on wholesale transactions, standard brands, are given below.

Date.	Electrolytic Copper.	Lead.	Spelter. St. Louis	Silver, per oz.
Feb. 13	14.87	4.33	6.05	61¾
" 14	14 81	4 33	6 03	61¾
" 15	14.81	4.33	6.00	62⅛
" 16	Sunday.	No market.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

F. L. Sizer is up from Arizona.

H. B. Lamb is in San Francisco.

Gelasio Caetani is in New York.

Frank Reber is here from National.

Edward de Villa is in San Francisco.

P. W. Hull is visiting San Francisco.

J. J. Multer is at Calistoga, California.

James Douglas has returned to New York.

O. B. Perry was in San Francisco this week.

Philip R. Stanhope has returned to Denver.

Thomas T. Read will leave today for Arizona.

James H. Hyde was in San Francisco recently.

A. D. Foote has been in San Francisco this week.

L. D. Ricketts has returned from a trip to the East.

O. H. Hershey passed through San Francisco last Saturday.

Charles Farnham and R. G. French are here from Grass Valley.

Sidney J. Jennings and Frederick Lyon were at Gold Road recently.

M. R. B. Gordon is now in charge at the Cobalt Lake mine, Ontario.

Lionel Lindsay expects to leave early in March for a visit to Japan.

Edgar Rickard arrived in New York Sunday and will visit California.

P. N. Moore attended the A. I. M. E. meeting in New York this week.

F. J. Basedow is up from Australia to visit American mining districts.

E. P. Jennings is now president of the Utah Metal Mining Company.

Karl Eilers is at Salt Lake City and is expected in San Francisco early in March.

R. B. Lamb has been appointed consulting engineer of the Peterson Lake mine, Cobalt.

O. B. Hart is now with the Andrada Mines Co., Macequece, Portuguese East Africa.

J. B. Tyrrell has returned to Toronto, after having spent two months in London, England.

Theodore B. Comstock is president of the California Farm & Home Builders at Los Angeles.

Leon J. Pepperberg has returned from professional work in the Santa Clara Valley oilfields.

George C. Stone has been elected treasurer of the American Institute of Mining Engineers.

L. L. Ferguson is now consulting engineer for the Triangle Mining & Development Company.

Howland Bancroft has been in the hospital at Denver for an appendicitis operation. He is recovering nicely.

At the weekly luncheon of the Engineers' Club of San Francisco next Tuesday at the Palace Hotel at 12:30, plans will be consummated for permanent quarters.

Norman C. Stines has left London for St. Petersburg, going by way of Paris and Berlin, having been appointed mining engineer to the Syssert Estate, in the Urals.

Louis Coderre, Secretary of State for the Dominion of Canada, now has charge of the Canadian Geological Survey and Bureau of Mines, which have been transferred from the Department of the Interior.

C. M. Eye expects to return to California soon, having resigned as manager for the Concheño Mining Co. in the Rayon district, Chihuahua. His temporary address is Box 571, Ocean Park, Los Angeles county.

Among those attending the recent conference called by the Director of the U. S. Bureau of Mines to consider problems relating to gas and oil wells in coalfields were: E. J. Taylor, W. C. Neill, F. W. De Wolf, Richard R. Hice, R. Dawson Hall, A. P. Cameron, A. C. Beeson, B. H. Canon, George W. Schluederberg, A. J. Moorshead, E. B. Moore, John W. Boileau, George S. Rice, O. P. Hood, H. M. Wilson, and Irving C. Allen.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

FATALITY rate in British Columbia mines is 5.24 per 1000 employed.

SALT is produced in the province of Szechuan, China, amounting to 300,000 tons per year, while the output of the districts tributary to the T'o river is 600,000 tons.

LAUNDERS at the Junction North mine are made of ⅛-in. steel plate in three sizes, 4 by 6, 5 by 8, and 7 by 12 in., parabolic in section, and in nearly every case the flow to different machines is made interchangeable.

WILFLEY tables at the Junction North mine, Broken Hill, are fitted with riffles ending in a special curve at the delivery end, the idea being to separate the fine lead from rhodonite gangue. Each table requires about 1 hp., and treats ¾ ton per hour.

CEMENT-GUNS were not invented by an engineer, a cement worker, or even a contractor or builder, but by C. F. Akeley, a taxidermist of Chicago. His idea for the use of the cement-gun was to rapidly and economically build up forms over which the skins of the larger mammals such as elephants and hippopotami might be placed.

ONE of the markets available for Alaska coal, were the coalfields of the territory developed, would be to supply coke to the smelters and foundries on Puget Sound and at Portland, San Francisco, Los Angeles, and the cities on the Pacific coast. Most of the coke now consumed on the Coast is imported from Germany, England, Australia, and China, or is brought from the Eastern states.

DATA for use in figuring requirements for gas-engine practice are as follows: One gallon of fuel oil contains 130,000 B.t.u.; 1 cu. ft. of water gas, for high heat work, contains 260 B.t.u.; 1 cu. ft. of mixed gas, for low heat work, contains 130 B.t.u.; 1 cu. ft. of producer gas, for gas-engine work, contains 95 B.t.u. An efficient gas-engine requires 10,000 B.t.u. per brake horse-power. One long ton of good bituminous coal will produce 40,000 cu. ft. of 260-B.t.u. water gas, or 120,000 cu. ft. of 95-B.t.u. producer gas.

MANGANESE exports from Bombay during the seven months ended October 1912 amounted to 272,795 long tons, of a value of $1,430,539. The shipments to the United States were 70,800 tons, worth $344,831. There was little change from the previous year in amount shipped. The manganese deposits of Central Uruguay will soon have an outlet through a 75-mile branch of the Central Uruguay railway, which is to be constructed from Tacurambo to Cerro Paraguay. The Government is to construct the branch and lease it to the Central railway at $1200 per mile per year.

GAS METERS require testing before use, and in Massachusetts, New York, California, and Maryland all of the meters used must be tested, sealed, and stamped by state officials. Special rules have been adopted in each. In Wisconsin and Nevada the companies are required to test all meters once in three years, and in New Jersey once in six years. The state inspectors test any meter upon formal complaint, but make no other routine meter tests. Certain local meter regulations are still in force in New Jersey, pending the decision of state authorities who are now investigating this matter.

AUTOMOBILE show at Chicago has set aside February 10 to 15 exclusively for the exhibition of commercial vehicles, and business men will be able to inspect them without being annoyed by people attracted by passenger vehicles. There are 77 exhibitors of complete wagons and trucks, of which 33 are specializing in those of 750 to 3000-lb. capacity. Delivery wagons of from 500 to 1000-lb. capacity, in both gasoline and electric types, are shown by 15 firms, prices ranging from $500 to $1800, and $700 to $2500. Seventeen firms have light trucks of 1500-lb. capacity, costing $750 to $2100; 25 show 2240-lb. trucks from $1100 to $2870 for the chassis without body, and 27 have 4480 to 5600-lb. trucks from $1800 to $3100. There will also be exhibits of 6720, 7840, 11,200, 12,320-lb. trucks, either electric or gasoline, with prices from $3100 to $5090. There are also exhibits of 15,680 and 22,400-lb. trucks. In all, there are 95 models of trucks from 500 to 5600 lb., and 72 models of 6720 to 22,400-lb. capacity.

WATER for mining purposes may be acquired on public lands, but certain precautions are to be noted. By locating, rights similar if not equal to those given by a patent are acquired; consequently, where riparian rights are recognized, a located or patented claim has a riparian right to use the water flowing through its ground. This right is not as conclusive as might be wished for, and consequently an appropriation should always be made. Where it is sought to divert the water off the claim having riparian rights, an appropriation must be made. In those states where riparian rights are not recognized, an appropriation must be made. In general, little reliance should be placed upon the riparian rights of a mining claim. Where an unappropriated flowing spring or well is upon a claim, under riparian rights, the claim-owner also owns the water; but where appropriation only is recognized, an appropriation of the flow at the point it leaves the ground of the claim-owner may be made by a stranger. What effect such an appropriation may have on the claim or land-owner's use of the water flowing from the spring or well is not clear; the safe course is to make an appropriation of the water naturally arising on one's own ground. Flowing water that develops naturally or is developed artificially after patent is obtained from the government, is private property and cannot be appropriated. Such water may come from the driving of wells, opening up new springs, driving tunnels, or from ponds arising naturally. The surplus of such water as it leaves the private land may be used and appropriated, but no real right is obtained, for the land-owner may cut off or divert the flow at his pleasure.
